Precision Low Drift 2.048 V/2.5 V/4.096 V/ 5.0 V SOT-23 Reference with Shutdown

ADR390/ADR391/ADR392/ADR395

FEATURES

Initial Accuracy: ±6 mV Max
Low TCV_O: 25 ppm/°C Max
Load Regulation: 60 ppm/mA
Line Regulation: 25 ppm/V
Low Supply Headroom: 0.3 V
Wide Operating Range: (V_{OUT} + 0.3 V) to 15 V
Low Power: 120 μA Max
Shutdown to Less Than 3 μA Max
Output Current: 5 mA
Wide Temperature Range:
–40°C to +85°C for ADR390, ADR391
–40°C to +125°C for ADR392, ADR395
Tiny 5-Lead SOT-23 Package

APPLICATIONS

Battery-Powered Instrumentation
Portable Medical Instruments
Data Acquisition Systems
Industrial Process Control Systems
Fault Protection Critical Systems
Automotive

GENERAL DESCRIPTION

The ADR390, ADR391, ADR392, and ADR395 are precision 2.048 V, 2.5 V, 4.096 V, and 5 V band gap voltage references featuring high accuracy and stability and low power consumption in a tiny footprint. Patented temperature drift curvature correction techniques minimize nonlinearity of the voltage change with temperature. The wide operating range and low power consumption with additional shutdown capability make them ideal for battery-powered applications. The V_{OUT} Sense Pin enables greater accuracy by supporting full Kelvin operation in PCBs employing thin or long traces.

The ADR390, ADR391, ADR392, and ADR395 are micropower, low dropout voltage (LDV) devices that provide a stable output voltage from supplies as low as 300 mV above the output voltage. ADR390 and ADR391 are specified over the industrial range (–40°C to +85°C), while ADR392 and ADR395 are specified over the extended industrial range (–40°C to +125°C). Each is available in the tiny 5-lead SOT-23 package.

The combination of V_{OUT} sense and shutdown functions also enables a number of unique applications combining precision reference/regulation with fault decision and overcurrent protection. Details are provided in the Applications section.

PIN CONFIGURATION
5-Lead SOT-23
(RT Suffix)

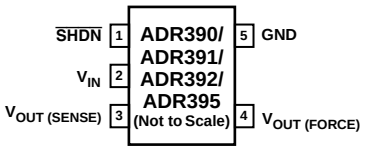

Table I. ADR39x Products

Part Number	Nominal Output Voltage (V)
ADR390	2.048
ADR391	2.500
ADR392	4.096
ADR395	5.000

NOTES
[1] Absolute Maximum Ratings apply at 25°C, unless otherwise noted.
[2] Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

ORDERING GUIDE

Model	Temperature Range	Package Description	Package Option	Top Mark	Output Voltage	Number of Parts Per Reel
ADR390ART–RL7	–40°C to +85°C	5-Lead SOT-23	RT-5	R0A	2.048	3,000
ADR390ART–RL	–40°C to +85°C	5-Lead SOT-23	RT-5	R0A	2.048	10,000

ADR392ART-RL	–40°C to +125°C	5-Lead SOT-23	RT-5	RCA	4.096	10,000
ADR395ART-RL7	–40°C to +125°C	5-Lead SOT-23	RT-5	RDA	5.000	3,000

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the ADR390/ADR391/ADR392/ADR395 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

PARAMETER DEFINITION

Temperature Coefficient (TCV_O)

The change of output voltage over the operating temperature change and normalized by the output voltage at 25°C, expressed in ppm/°C. The equation follows:

$$TCV_O\left[ppm/^\circ C\right] = \frac{V_O\left(T_2\right) - V_O\left(T_1\right)}{V_O\left(25^\circ C\right) \times \left(T_2 - T_1\right)} \times 10^6$$

where:

$V_O(25°C)$ = V_O at 25°C

$V_O(T_1)$ = V_O at temperature1

$V_O(T_2)$ = V_O at temperature2

Line Regulation ($\Delta V_O/\Delta V_{IN}$)

The change in output voltage due to a specified change in input voltage. It includes the effects of self-heating. Line regulation is expressed in either percent per volt, parts per million per volt, or microvolts per volt change in input voltage.

Load Regulation ($\Delta V_O/\Delta I_{LOAD}$)

The change in output voltage due to a specified change in load current. It includes the effects of self-heating. Load regulation is expressed in either microvolts per milliampere, parts per million per milliampere, or Ω of dc output resistance.

Input Capacitor

Input capacitors are not required on the ADR39x. There is no limit for the value of the capacitor used on the input, but a 1 µF to 10 µF capacitor on the input will improve transient response in applications where the supply suddenly changes. An additional 0.1 µF in parallel will also help in reducing noise from the supply.

Output Capacitor

The ADR39x does not need output capacitors for stability under any load condition. An output capacitor, typically 0.1 µF, will filter out any low level noise voltage and will not affect the operation of the part. On the other hand, the load transient response can be improved with an additional 1 µF to 10 µF output capacitor in parallel. A capacitor here will act as a source of stored energy for a sudden increase in load current. The only parameter that will degrade, by adding an output capacitor, is turn-on time and it depends on the size of the capacitor chosen.

Long-Term Stability

Typical shift in output voltage over 1000 hours at a controlled temperature. Figure 1 shows a sample of parts measured at different intervals in a controlled environment of 50°C for 1000 hours.

$$\Delta V_O = V_O\left(t_0\right) - V_O\left(t_1\right)$$

$$\Delta V_O\left[ppm\right] = \frac{V_O\left(t_0\right) - V_O\left(t_1\right)}{V_O\left(t_0\right)} \times 10^6$$

where:

$V_O(t_0)$ = V_O at time 0

$V_O(t_1)$ = V_O after 1000 hours operation at a controlled temperature

Thermal Hysteresis (V_{O_HYS})

The change of output voltage after the device is cycled through temperature from +25°C to –40°C to +85°C and back to +25°C. This is a typical value from a sample of parts put through such a cycle.

$$V_{O\_HYS} = V_O\left(25^\circ C\right) - V_{O\_TC}$$

$$V_{O\_HYS}\left[ppm\right] = \frac{V_O\left(25^\circ C\right) - V_{O\_TC}}{V_O\left(25^\circ C\right)} \times 10^6$$

where:

$V_O(25°C)$ = V_O at 25°C

V_{O_TC} = V_O at 25°C after temperature cycle at +25°C to –40°C to +85°C and back to +25°C

THEORY OF OPERATION

Band gap references are the high performance solution for low supply voltage and low power voltage reference applications, and the ADR390/ADR391/ADR392/ADR395 is no exception. The uniqueness of this product lies in its architecture. By observing Figure 2, the ideal zero TC band gap voltage is referenced to the output, not to ground. Therefore, if noise exists on the ground line, it will be greatly attenuated on V_{OUT}. The band gap cell consists of the pnp pair Q51 and Q52, running at unequal current densities. The difference in V_{BE} results in a voltage with a positive TC, which is amplified by the ratio of $2\times\frac{R58}{R54}$. This PTAT voltage, combined with V_{BE}s of Q51 and Q52, produces the stable band gap voltage.

Reduction in the band gap curvature is performed by the ratio of the resistors R44 and R59, one of which is linearly temperature dependent. Precision laser trimming and other patented circuit techniques are used to further enhance the drift performance.

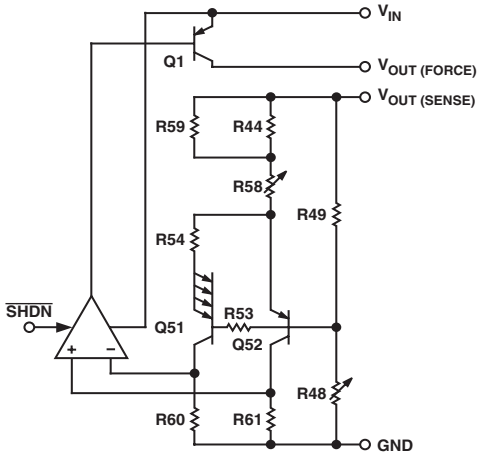

Figure 2. Simplified Schematic

Device Power Dissipation Considerations

The ADR390/ADR391/ADR392/ADR395 is capable of delivering load currents to 5 mA with an input voltage that ranges from 2.8 V (ADR391 only) to 15 V. When this device is used in applications with large input voltages, care should be taken to avoid exceeding the specified maximum power dissipation or junction temperature that could result in premature device failure. The following formula should be used to calculate a device's maximum junction temperature or dissipation:

$$P_D = \frac{T_J - T_A}{\theta_{JA}}$$

In this equation, T_J and T_A are, respectively, the junction and ambient temperatures, P_D is the device power dissipation, and θ_{JA} is the device package thermal resistance.

Shutdown Mode Operation

The ADR390/ADR391/ADR392/ADR395 includes a shutdown feature that is TTL/CMOS level compatible. A logic LOW or a zero volt condition on the $\overline{SHDN}$ Pin is required to turn the device off. During shutdown, the output of the reference becomes a high impedance state where its potential would then be determined by external circuitry. If the shutdown feature is not used, the $\overline{SHDN}$ Pin should be connected to V_{IN} (Pin 2).

APPLICATIONS

BASIC VOLTAGE REFERENCE CONNECTION

The circuit in Figure 3 illustrates the basic configuration for the ADR39x family. Decoupling capacitors are not required for circuit stability. The ADR39x family is capable of driving capacitive loads from 0 µF to 10 µF. However, a 0.1 µF ceramic output capacitor is recommended to absorb and deliver the charge as is required by a dynamic load.

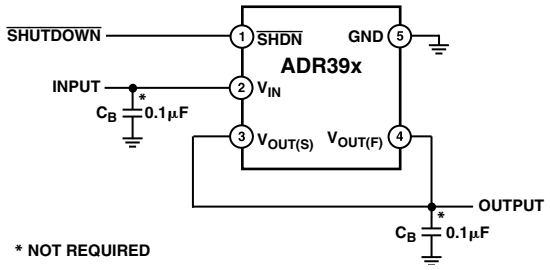

Figure 3. Basic Configuration for the ADR39x Family

Stacking Reference ICs for Arbitrary Outputs

Some applications may require two reference voltage sources, which are a combined sum of standard outputs. Figure 4 circuit shows how this "stacked output" reference can be implemented:

OUTPUT TABLE

U1/U2	V_{OUT1} (V)	V_{OUT2} (V)
ADR390/ADR390	2.048	4.096
ADR391/ADR391	2.5	5.0
ADR392/ADR392	4.096	8.192
ADR395/ADR395	5	10

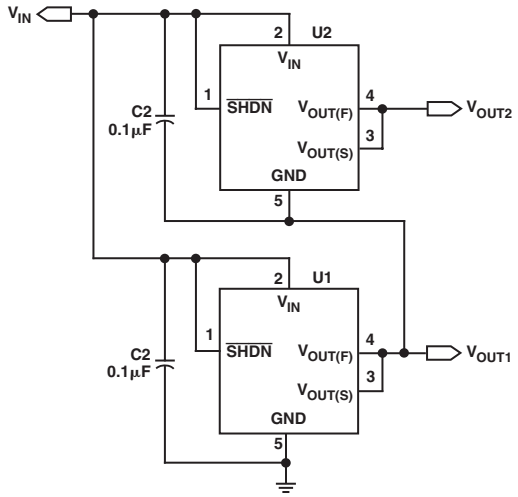

Figure 4. Stacking Voltage References with the ADR390/ADR391/ADR392/ADR395

Two reference ICs are used, fed from an unregulated input, V_{IN}. The outputs of the individual ICs are simply connected in series, which provides two output voltages V_{OUT1} and V_{OUT2}. V_{OUT1} is the terminal voltage of U1, while V_{OUT2} is the sum of this voltage and the terminal voltage of U2. U1 and U2 are simply chosen for the two voltages that supply the required outputs (see Output Table). For example, if both U1 and U2 are ADR391s, V_{OUT1} is 2.5 V and V_{OUT2} is 5.0 V.

While this concept is simple, a precaution is in order. Since the lower reference circuit must sink a small bias current from U2, plus the base current from the series PNP output transistor in U2, either the external load of U1 or R1 must provide a path for this current. If the U1 minimum load is not well defined, the resistor R1 should be used, set to a value that will conservatively pass 600 µA of current with the applicable V_{OUT1} across it. Note that the two U1 and U2 reference circuits are locally treated as macrocells, each having its own bypasses at input and output for best stability. Both U1 and U2 in this circuit can source dc currents up to their full rating. The minimum input voltage, V_{IN}, is determined by the sum of the outputs, V_{OUT2}, plus the dropout voltage of U2.

A Negative Precision Reference without Precision Resistors

A negative reference can be easily generated by adding an op amp, A1, and configured as shown in Figure 5. V_{OUTF} and V_{OUTS} are at virtual ground and therefore the negative reference can be taken directly from the output of the op amp. The op amp must be dual supply, low offset, and rail-to-rail if the negative supply voltage is close to the reference output.

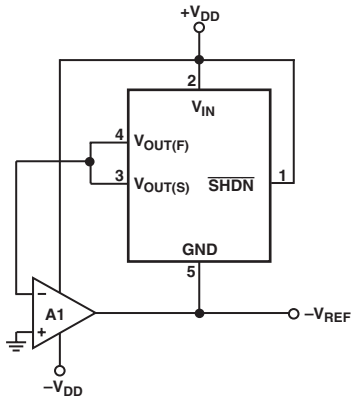

Figure 5. Negative Reference

General-Purpose Current Source

Many times in low power applications, the need arises for a precision current source that can operate on low supply voltages. As shown in Figure 6, the ADR390/ADR391/ADR392/ADR395 can be configured as a precision current source. The circuit configuration illustrated is a floating current source with a grounded load. The reference's output voltage is bootstrapped across R_{SET}, which sets the output current into the load. With this configuration, circuit precision is maintained for load currents in the range from the reference's supply current, typically 90 µA to approximately 5 mA.

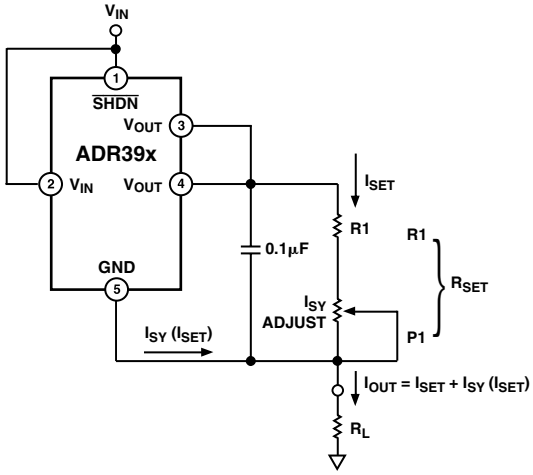

Figure 6. A General-Purpose Current Source

High Power Performance with Current Limit

In some cases, the user may want higher output current delivered to a load and still achieve better than 0.5% accuracy out of the ADR39x. The accuracy for a reference is normally specified on the data sheet with no load. However, the output voltage changes with load current.

The circuit in Figure 7 provides high current without compromising the accuracy of the ADR39x. The series pass transistor Q1 provides up to 1 A load current. The ADR39x delivers only the base drive to Q1 through the force pin. The sense pin of the ADR39x is a regulated output and is connected to the load.

The transistor Q2 protects Q1 during short circuit limit faults by robbing its base drive. The maximum current is $I_{LMAX} \approx 0.6\ V/R_S$.

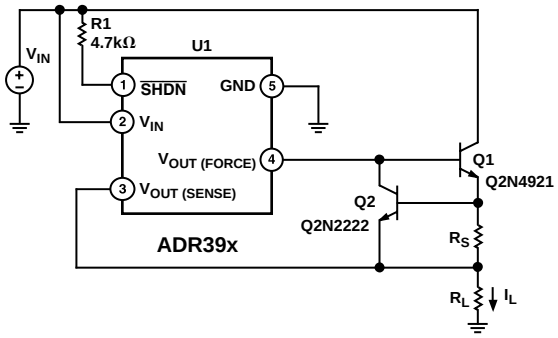

Figure 7. ADR39x for High Power Performance with Current Limit

A similar circuit function can also be achieved with the Darlington transistor configuration (see Figure 8).
