

System Peripheral Clock Source

Description

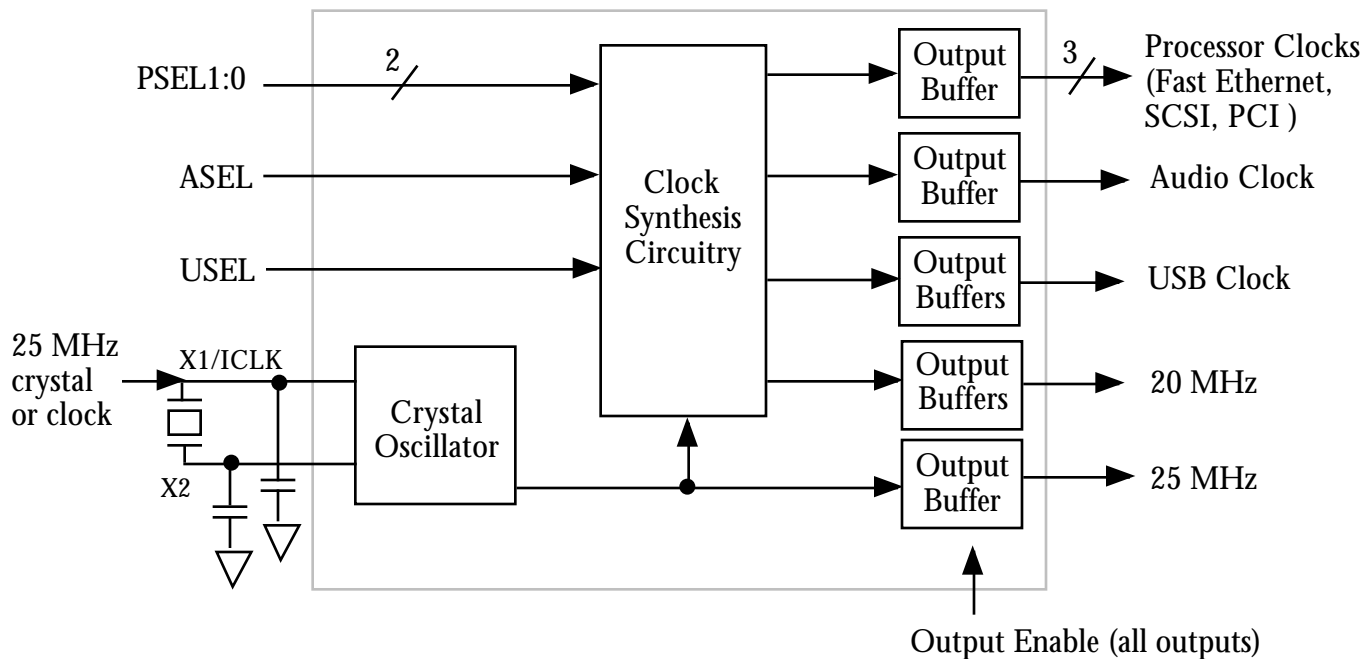

The ICS650-21 is a low cost, low jitter, high performance clock synthesizer for system peripheral applications. Using analog/digital Phase-Locked Loop (PLL) techniques, the device accepts a parallel resonant 25 MHz crystal input to produce up to eight output clocks. The device provides clocks for PCI, SCSI, Fast Ethernet, Ethernet, USB, and AC97. The user can select one of three USB frequencies, and also one of two AC97 audio frequencies. The OE pin puts all outputs into a high impedance state for board level testing. All frequencies are generated with less than one ppm error, meeting the demands of SCSI and Ethernet clocking.

The ICS650 can be mask customized to produce any frequencies from 1 to 150 MHz.

External Components

The ICS650 requires a minimum number of external components for proper operation. Decoupling capacitors of 0.1µF should be connected between VDD and GND (on pins 4 and 6, and pins 16 and 14), as close to the chip as possible. A series termination resistor of 33Ω may be used for each clock output. The 25.000 MHz crystal must be connected as close to the chip as possible. The crystal should be a fundamental mode, parallel resonant, 30ppm or better (to meet the Ethernet specs). Crystal capacitors should be connected from pins X1 to ground and X2 to ground. The value of these capacitors is given by the following equation, where C_L is the crystal load capacitance: Crystal caps (pF) = $(C_L - 12) \times 2$. So for a crystal with 16pF load capacitance, two 8pF caps should be used. If a clock input is used, drive it into X1 and leave X2 unconnected.
