## FLASH MEMORY

## CMOS

## 4M ( $512 \mathrm{~K} \times 8$ ) BIT

## MBM29F040C-55/-70/-90

## ■ FEATURES

- Single 5.0 V read, program and erase

Minimizes system level power requirements

- Compatible with JEDEC-standard commands

Uses same software commands as E ${ }^{2}$ PROMs

- Compatible with JEDEC-standard byte-wide pinouts

32-pin PLCC (Package suffix: PD)
32-pin TSOP(I) (Package suffix: PF)
32-pin TSOP(I) (Package suffix: PFTN - Normal Bend Type, PFTR - Reversed Bend Type)

- Minimum 100,000 write/erase cycles
- High performance

55 ns maximum access time

- Sector erase architecture

8 equal size sectors of 64 K bytes each
Any combination of sectors can be concurrently erased. Also supports full chip erase.

- Embedded Erase ${ }^{\text {TM }}$ Algorithms

Automatically pre-programs and erases the chip or any sector

- Embedded Program ${ }^{\text {TM }}$ Algorithms

Automatically writes and verifies data at specified address

- Data Polling and Toggle Bit feature for detection of program or erase cycle completion
- Low Vcc write inhibit $\leq 3.2 \mathrm{~V}$
- Sector protection

Hardware method disables any combination of sectors from write or erase operations

- Erase Suspend/Resume

Suspends the erase operation to allow a read data in another sector within the same device

## MBM29F040C-55/-70-90

## PACKAGE

32-pin Plastic QFJ (PLCC)

## MBM29F040C-55/-70/-90

## ■ GENERAL DESCRIPTION

The MBM29F040C is a 4M-bit, 5.0 V-only Flash memory organized as 512 K bytes of 8 bits each. The MBM29F040C is offered in a 32 -pin PLCC and 32 -pin TSOP(I) package. This device is designed to be programmed in-system with the standard system 5.0 V Vcc supply. A 12.0 V Vp is not required for write or erase operations. The device can also be reprogrammed in standard EPROM programmers.
The standard MBM29F040C offers access times 55 ns and 90 ns , allowing operation of high-speed microprocessors without wait states. To eliminate bus contention the device has separate chip enable ( $\overline{\mathrm{CE}}$ ), write enable ( $\overline{\mathrm{WE}}$ ), and output enable ( $\overline{\mathrm{OE}}$ ) controls.

The MBM29F040C is pin and command set compatible with JEDEC standard E²PROMs. Commands are written to the command register using standard microprocessor write timings. Register contents serve as input to an internal state-machine which controls the erase and programming circuitry. Write cycles also internally latch addresses and data needed for the programming and erase operations. Reading data out of the device is similar to reading from 12.0 V Flash or EPROM devices.
The MBM29F040C is programmed by executing the program command sequence. This will invoke the Embedded Program Algorithm which is an internal algorithm that automatically times the program pulse widths and verifies proper cell margin. Typically, each sector can be programmed and verified in less than 0.5 seconds. Erase is accomplished by executing the erase command sequence. This will invoke the Embedded Erase Algorithm which is an internal algorithm that automatically preprograms the array if it is not already programmed before executing the erase operation. During erase, the device automatically times the erase pulse widths and verifies proper cell margin.
Any individual sector is typically erased and verified in 1 second. (If already completely preprogrammed.)
The device also features a sector erase architecture. The sector mode allows for 64 K byte sectors of memory to be erased and reprogrammed without affecting other sectors. The MBM29F040C is erased when shipped from the factory.

The device features single 5.0 V power supply operation for both read and write functions. Internally generated and regulated voltages are provided for the program and erase operations. A low Vcc detector automatically inhibits write operations on the loss of power. The end of program or erase is detected by Data Polling of DQ ${ }_{7}$ or by the Toggle Bit feature on $\mathrm{DQ}_{6}$. Once the end of a program or erase cycle has been completed, the device internally resets to the read mode.
Fujitsu's Flash technology combines years of EPROM and E2PROM experience to produce the highest levels of quality, reliability and cost effectiveness. The MBM29F040C memory electrically erases the entire chip or all bits within a sector simultaneously via Fowler-Nordheim tunneling. The bytes are programmed one byte at a time using the EPROM programming mechanism of hot electron injection.

## MBM29F040C-55/-70-90

## FLEXIBLE SECTOR-ERASE ARCHITECTURE

- 64 K Byte per sector
- Individual-sector, multiple-sector, or bulk-erase capability
- Individual or multiple-sector protection is user definable

## ORDERING INFORMATION

## Standard Products

Fujitsu standard products are available in several packages. The order number is formed by a combination of:

## MBM29F040C-55/-70/-90

## ■ FUNCTIONAL DESCRIPTION

## Read Mode

The MBM29F040C has two control functions which must be satisfied in order to obtain data at the outputs. $\overline{C E}$ is the power control and should be used for a device selection. $\overline{O E}$ is the output control and should be used to gate data to the output pins if a device is selected.
Address access time (tacc) is equal to the delay from stable addresses to valid output data. The chip enable access time (tce) is the delay from stable addresses and stable $\overline{\mathrm{CE}}$ to valid data at the output pins. The output enable access time is the delay from the falling edge of OE to valid data at the output pins (assuming the addresses have been stable for at least tacc-toe time).

## Standby Mode

The MBM29F040C has two standby modes, a CMOS standby mode ( $\overline{\mathrm{CE}}$ input held at $\mathrm{V}_{\mathrm{cc}} \pm 0.3 \mathrm{~V}$.), when the current consumed is less than $5 \mu \mathrm{~A}$; and a TTL standby mode ( $\overline{\mathrm{CE}}$ is held at $\mathrm{V}_{H}$ ) when the current required is reduced to approximately 1 mA . During Embedded Algorithm operation, Vcc Active current (Iccz) is required even $\overline{\mathrm{CE}}=\mathrm{V}_{\text {IH. }}$. The device can be read with standard access time (tcE) from either of these standby modes. In the standby mode the outputs are in a high impedance state, independent of the $\overline{\mathrm{OE}}$ input.

If the device is deselected during erasure or programming, the device will draw active current until the operation is completed.

## Output Disable

With the $\overline{\mathrm{OE}}$ input at a logic high level $\left(\mathrm{V}_{\mathrm{H}}\right)$, output from the device is disabled. This will cause the output pins to be in a high impedance state.

## Autoselect

The autoselect mode allows the reading out of a binary code from the device and will identify its manufacturer and type. This mode is intended for use by programming equipment for the purpose of automatically matching the device to be programmed with its corresponding programming algorithm. This mode is functional over the entire temperature range of the device.

To activate this mode, the programming equipment must force $\mathrm{V}_{\mathrm{ID}}(11.5 \mathrm{~V}$ to 12.5 V ) on address pin Ag. Two identifier bytes may then be sequenced from the device outputs by toggling address $A_{o}$ from VIL to $\mathrm{V}_{\mathrm{IH}}$. All addresses are DON'T CARES except $\mathrm{A}_{0}, \mathrm{~A}_{1}$, and $\mathrm{A}_{6}$. (Recommend $\mathrm{V}_{\mathrm{IL}}$ for the other pins.)

The manufacturer and device codes may also be read via the command register, for instances when the MBM29F040C is erased or programmed in a system without access to high voltage on the As pin. The command sequence is illustrated in Table 5. (Refer to Autoselect Command section.)
Byte $0\left(A_{0}=V_{L L}\right)$ represents the manufacture's code (Fujitsu $\left.=04 \mathrm{H}\right)$ and byte $1\left(A_{0}=V_{H}\right)$ represents the device identifier code (MBM29F040C = A4H). These two bytes are given in the Table 3. All identifiers for manufactures and device will exhibit odd parity with the MSB (DQ7) defined as the parity bit. In order to read the proper device codes when executing the autoselect, $\mathrm{A}_{1}$ must be VIL. (See Table 3.)

## MBM29F040C-55/-70/-90

## Write

Device erasure and programming are accomplished via the command register. The contents of the register serve as inputs to the internal state machine. The state machine outputs dictate the function of the device.

The command register itself does not occupy any addressable memory location. The register is a latch used to store the commands, along with the address and data information needed to execute the command. The command register is written by bringing $\overline{\mathrm{WE}}$ to $\mathrm{V}_{\mathrm{LL}}$, while $\overline{\mathrm{CE}}$ is at $\mathrm{V}_{\mathrm{IL}}$ and $\overline{\mathrm{OE}}$ is at $\mathrm{V}_{\mathrm{H}}$. Addresses are latched on the falling edge of $\overline{\mathrm{WE}}$ or $\overline{\mathrm{CE}}$, whichever happens later; while data is latched on the rising edge of $\overline{\mathrm{WE}}$ or $\overline{\mathrm{CE}}$, whichever happens first. Standard microprocessor write timings are used.
Refer to AC Write Characteristics and the Erase/Programming Waveforms for specific timing parameters.

## Sector Protection

The MBM29F040C features hardware sector protection. This feature will disable both program and erase operations in any number of sectors ( 0 through 8 ). The sector protection feature is enabled using programming equipment at the user's site. The device is shipped with all sectors unprotected.
To activate this mode, the programming equipment must force $\mathrm{V}_{\mathrm{ID}}$ on address pin $\mathrm{A}_{9}$ and control pin $\overline{\mathrm{OE}}$, (suggest $\mathrm{V}_{10}=11.5 \mathrm{~V}$ ) and $\overline{\mathrm{CE}}=\mathrm{V}_{1+}$. The sector addresses ( $\mathrm{A}_{18}, \mathrm{~A}_{17}$ and $\mathrm{A}_{16}$ ) should be set to the sector to be protected. Table 4 defines the sector address for each of the eight (8) individual sectors. Programming of the protection circuitry begins on the falling edge of the $\overline{\mathrm{WE}}$ pulse and is terminated with the rising edge of the same. Sector addresses must be held constant during the $\overline{\mathrm{WE}}$ pulse. See figures 11 and 17 sector protection waveforms and algorithm.

## MBM29F040C-55/-70/-90

To verify programming of the protection circuitry, the programming equipment must force $\mathrm{V}_{\text {ID }}$ on address pin $\mathrm{A}_{9}$ with $\overline{\mathrm{CE}}$ and $\overline{\mathrm{OE}}$ at $\mathrm{V}_{1 \mathrm{~L}}$ and $\overline{\mathrm{WE}}$ at $\mathrm{V}_{14}$. Scanning the sector addresses ( $\mathrm{A}_{16}, \mathrm{~A}_{17}$ and $\mathrm{A}_{18}$ ) while ( $\left.\mathrm{A}_{6}, \mathrm{~A}_{1}, \mathrm{~A}_{0}\right)=(0$, 1,0 ) will produce a logical " 1 " code at device output $\mathrm{DQ}_{0}$ for a protected sector. Otherwise the device will read 00 H for unprotected sector. In this mode, the lower order addresses, except for $A_{0}, A_{1}$ and $A_{6}$ are DON'T CARES. Address locations with $A_{1}=V_{I L}$ are reserved for Autoselect manufacturer and device codes.

It is also possible to determine if a sector is protected in the system by writing an Autoselect command. Performing a read operation at the address location $\mathrm{XX02H}$, where the higher order addresses ( $\mathrm{A}_{16}, \mathrm{~A}_{17}$ and $\mathrm{A}_{18}$ ) are the sector address will produce a logical "1" at DQo for a protected sector. See Table 3 for Autoselect codes.

Table 5 MBM29F040C Command Definitions

| Command <br> Sequence <br> Read/Reset | $\begin{gathered} \text { Bus } \\ \text { Wyite } \\ \text { Cycles } \\ \text { Req'd } \end{gathered}$ | First Bus Write Cycle |  | Second Bus Write Cycle |  | Third Bus Write Cycle |  | Fourth Bus Read/Write Cycle |  | Fifth Bus Write Cycle |  | Sixth Bus Write Cycle |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  |  | Addr | Data | Addr | Data | Addr | Data | Addr | Data | Addr | Data | Addr | Data |

| Chip Erase | 6 | 555H | AAH | 2AAH | 55H | 555H | 80H | 555H | AAH | 2AAH | 55H | 555H | 10H |
| Sector Erase | 6 | 555H | AAH | 2AAH | 55H | 555H | 80 H | 555H | AAH | 2AAH | 55H | SA | 30 H |
| Sector Erase Suspend |  | Erase can be suspended during sector erase with Addr ("H" or "L"). Data (BOH) |  |  |  |  |  |  |  |  |  |  |  |
| Sector Erase Resume |  | Erase can be resumed after suspend with Addr ("H" or "L"). Data (30H) |  |  |  |  |  |  |  |  |  |  |  |

Notes: 1. Address bits $\mathrm{A}_{11}$ to $\mathrm{A}_{18}=\mathrm{X}=$ "H" or "L" for all address commands except for Program Address (PA) and Sector Address (SA).
2. Bus operations are defined in Table 2.
3. $R A=$ Address of the memory location to be read.

PA = Address of the memory location to be programmed. Addresses are latched on the falling edge of the WE pulse.
$S A=$ Address of the sector to be erased. The combination of $A_{18}, A_{17}$, and $A_{16}$ will uniquely select any sector.
4. $\mathrm{RD}=$ Data read from location RA during read operation.
$\mathrm{PD}=$ Data to be programmed at location PA. Data is latched on the falling edge of $\overline{\mathrm{WE}}$.
*: Either of the two reset commands will reset the device.

## Command Definitions

Device operations are selected by writing specific address and data sequences into the command register. Writing incorrect address and data values or writing them in the improper sequence will reset the device to read mode. Table 5 defines the valid register command sequences. Note that the Erase Suspend (BOH) and Erase Resume $(30 \mathrm{H})$ commands are valid only while the Sector Erase operation is in progress. Moreover, both Read/ Reset Commands are functionally equivalent, resetting the device to the read mode.

## MBM29F040C-55/-70/-90

## Read/Reset Command

The read or reset operation is initiated by writing the Read/Reset command sequence into the command register. Microprocessor read cycles retrieve array data from the memory. The device remains enabled for reads until the command register contents are altered.

The device will automatically power-up in the read/reset state. In this case, a command sequence is not required to read data. Standard microprocessor read cycles will retrieve array data. This default value ensures that no spurious alteration of the memory content occurs during the power transition. Refer to the AC Read Characteristics and Waveforms for the specific timing parameters.

## Autoselect Command

Flash memories are intended for use in applications where the local CPU alters memory contents. As such, manufacture and device codes must be accessible while the device resides in the target system. PROM programmers typically access the signature codes by raising $\mathrm{A}_{9}$ to a high voltage ( $\mathrm{V}_{\mathrm{ID}}=11.5 \mathrm{~V}$ to 12.5 ). However, multiplexing high voltage onto the address lines is not generally desired system design practice.

The device contains an Autoselect command operation to supplement traditional PROM programming methodology. The operation is initiated by writing the Autoselect command sequence into the command register. Following the command write, a read cycle from address XX00H retrieves the manufacture code of 04 H . A read cycle from address $\mathrm{XX01H}$ returns the device code A4H. (see Table 3.) All manufacturer and device codes will exhibit odd parity with the MSB (DQ7) defined as the parity bit.
Sector state (protection or unprotection) will be informed address XX02H.
Scanning the sector addresses ( $A_{16}, A_{17}, A_{18}$ ) while ( $\left.A_{6}, A_{1}, A_{0}\right)=(0,1,0)$ will produce a logical " 1 " at device output $\mathrm{DQ}_{0}$ for a protected sector. The programming verification should be perform margin mode on the protected sector. (See Table 2 and 3.)
To terminate the operation, it is necessary to write the Read/Reset command sequence into the register, and also to write the Autoselect command during the operation, execute it after writing Read/Reset command sequence.

## Byte Programming

The device is programmed on a byte-by-byte basis. Programming is a four bus cycle operation. There are two "unlock" write cycles. These are followed by the program setup command and data write cycles. Addresses are latched on the falling edge of $\overline{\mathrm{CE}}$ or $\overline{\mathrm{WE}}$, whichever happens later and the data is latched on the rising edge of $\overline{\mathrm{CE}}$ or $\overline{\mathrm{WE}}$, whichever happens first. The rising edge of $\overline{\mathrm{CE}}$ or $\overline{\mathrm{WE}}$ (whichever happens first) begins programming. Upon executing the Embedded Program Algorithm command sequence, the system is not required to provide further controls or timings. The device will automatically provide adequate internally generated program pulses and verify the programmed cell margin.

The automatic programming operation is completed when the data on $\mathrm{DQ}_{7}$ is equivalent to data written to this bit (See Write Operation Status section.) at which time the device returns to the read mode and addresses are no longer latched. (See Table 6, Hardware Sequence Flags.) Therefore, the device requires that a valid address to the device be supplied by the system at this particular instance of time. Hence, Data Polling must be performed at the memory location which is being programmed.

Any commands written to the chip during this period will be ignored.
Programming is allowed in any sequence and across sector boundaries. Beware that a data "0" cannot be programmed back to a " 1 ". Attempting to do so may either hang up the device (Exceed timing limits.), or result in an apparent success according to the data polling algorithm but a read from reset/read mode will show that the data is still " 0 ". Only erase operations can convert " 0 " $s$ to " 1 " $s$.

Figure 13 illustrates the Embedded Program ${ }^{\top}$ M Algorithm using typical command strings and bus operations.

## MBM29F040C-55/-70/-90

## Chip Erase

Chip erase is a six bus cycle operation. There are two "unlock" write cycles. These are followed by writing the "set-up" command. Two more "unlock" write cycles are then followed by the chip erase command.
Chip erase does not require the user to program the device prior to erase. Upon executing the Embedded Erase Algorithm command sequence the device will automatically program and verify the entire memory for an all zero data pattern prior to electrical erase. The system is not required to provide any controls or timings during these operations.
The automatic erase begins on the rising edge of the last $\overline{W E}$ pulse in the command sequence and terminates when the data on DQ7 is " 1 " (see Write Operation Status section.) at which time the device returns to read the mode.

Figure 14 illustrates the Embedded Erase Algorithm using typical command strings and bus operations.

## Sector Erase

Sector erase is a six bus cycle operation. There are two "unlock" write cycles. These are followed by writing the "set-up" command. Two more "unlock" write cycles are then followed by the Sector Erase command. The sector address (Any address location within the desired sector.) is latched on the falling edge of WE, while the command (Data $=30 \mathrm{H}$ ) is latched on the rising edge of $\overline{\mathrm{WE}}$. A time-out of $50 \mu \mathrm{~s}$ from the rising edge of the last sector erase command will initiate the sector erase command(s).

Multiple sectors may be erased concurrently by writing the six bus cycle operations as described above. This sequence is followed with writes of the Sector Erase command to addresses in other sectors desired to be concurrently erased. The time between writes must be less than $50 \mu \mathrm{~s}$, otherwise that command will not be accepted. It is recommended that processor interrupts be disabled during this time to guarantee this condition. The interrupts can be re-enabled after the last Sector Erase command is written. A time-out of $50 \mu \mathrm{~s}$ from the rising edge of the last $\overline{W E}$ will initiate the execution of the Sector Erase command(s). If another falling edge of the WE occurs within the $50 \mu$ s time-out window the timer is reset. (Monitor $\mathrm{DQ}_{3}$ to determine if the sector erase timer window is still open, see section DQ 3 , Sector Erase Timer.) Any command other than Sector Erase or Erase Suspend during this time-out period will reset the device to read mode, ignoring the previous command string. Resetting the device once execution has begun will corrupt the data in the sector. In that case, restart the erase on those sectors and allow them to complete. (Refer to the Write Operation Status section for Sector Erase Timer operation.) Loading the sector erase buffer may be done in any sequence and with any number of sectors (1 to 7 ).

Sector erase does not require the user to program the device prior to erase. The device automatically programs all memory locations in the sector(s) to be erased prior to electrical erase. When erasing a sector or sectors the remaining unselected sectors are not affected. The system is not required to provide any controls or timings during these operations.

The automatic sector erase begins after the $50 \mu \mathrm{~s}$ time out from the rising edge of the $\overline{\mathrm{WE}}$ pulse for the last sector erase command pulse and terminates when the data on DQ $\mathrm{D}_{7}$ is " 1 " (See Write Operation Status section.) at which time the device returns to read mode. During the execution of the Sector Erase command, only the Erase Suspend and Erase Resume commands are allowed. All other commands will reset the device to read mode. Data polling must be performed at an address within any of the sectors being erased.
Figure 14 illustrates the Embedded Erase ${ }^{\text {TM }}$ Algorithm using typical command strings and bus operations.

## MBM29F040C-55/-70/-90

## Erase Suspend

The Erase Suspend command allows the user to interrupt a Sector Erase operation and then perform data reads from or programs to a sector not being erased. This command is applicable ONLY during the Sector Erase operation which include the time-out period for sector erase. The Erase Suspend command will be ignored if written during the Chip Erase operation or Embedded Program Algorithm. Writting the Erase Suspend command during the Sector Erase time-out results in immediate termination of the time-out period and suspension of the erase operation.

Any other command written during the Erase Suspend mode will be ignored except the Erase Resume command. Writing the Erase Resume command resumes the erase operation. The addresses are "DON'T CARES" when writing the Erase Suspend or Erase Resume command.

When the Erase Suspend command is written during the Sector Erase operation, the device will take a maximum of $10 \mu \mathrm{~s}$ to suspend the erase operation. When the devices have entered the erase-suspended mode, the DQ7 bit will be at logic " 1 ", and DQ 6 will stop toggling. The user must use the address of the erasing sector for reading $\mathrm{DQ}_{6}$ and $\mathrm{DQ}_{7}$ to determine if the erase operation has been suspended. Further writes of the Erase Suspend command are ignored.
When the erase operation has been suspended, the devices default to the erase-suspend-read mode. Reading data in this mode is the same as reading from the standard read mode except that the data must be read from sectors that have not been erase-suspended. Successively reading from the erase-suspended sector while the device is in the erase-suspend-read mode will cause $\mathrm{DQ}_{2}$ to toggle. (See the section on $\mathrm{DQ}_{2}$.)
After entering the erase-suspend-read mode, the user can program the device by writing the appropriate command sequence for Program. This Program mode is known as the erase-suspend-program mode. Again, programming in this mode is the same as programming in the regular Program mode except that the data must be programmed to sectors that are not erase-suspended. Successively reading from the erase-suspended sector while the devices are in the erase-suspend-program mode will cause $\mathrm{DQ}_{2}$ to toggle. The end of the erasesuspended Program operation is detected by Data polling of DQ7, or by the Toggle Bit I (DQ6) which is the same as the regular Program operation. Note that $\mathrm{DQ}_{7}$ must be read from the Program address while $\mathrm{DQ}_{6}$ can be read from any address.

To resume the operation of Sector Erase, the Resume command $(30 \mathrm{H})$ should be written. Any further writes of the Resume command at this point will be ignored. Another Erase Suspend command can be written after the chip has resumed erasing.

## MBM29F040C-55/-70/-90

## Write Operation Status

Table 6 Hardware Sequence Flags

| Status |  |  | DQ ${ }_{7}$ | DQ6 | DQ5 | DQ ${ }^{\text {a }}$ | DQ ${ }_{2}$ |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: | :---: |
| In Progress | Embedded Program Algorithm |  | $\overline{\mathrm{DQ}}_{7}$ | Toggle | 0 | 0 | 1 |
|  | Embedded Erase Algorithm |  | 0 | Toggle | 0 | 1 | Toggle |
|  | Erase Suspended Mode | Erase Suspend Read (Erase Suspended Sector) | 1 | 1 | 0 | 0 | Toggle |
|  |  | Erase Suspend Read (Non-Erase Suspended Sector) | Data | Data | Data | Data | Data |
|  |  | Erase Suspend Program Non-Erase Suspended Sector) | $\overline{\mathrm{DQ}}_{7}$ | Toggle (Note 1) | 0 | 0 | (Note 2) |
| Exceeded Time Limits | Embedded Program Algorithm |  | $\overline{\mathrm{DQ}}_{7}$ | Toggle | 1 | 0 | 1 |
|  | Program/Erase in Embedded Erase Algorithm |  | 0 | Toggle | 1 | 1 | N/A |
|  | Erase <br> Suspended <br> Mode | Erase Suspend Program (Non-Erase Suspended Sector) | $\overline{\mathrm{DQ}}{ }_{7}$ | Toggle | 1 | 0 | N/A |

Notes: 1. Performing successive read operations from any address will cause $\mathrm{DQ}_{6}$ to toggle.
2. Reading the byte address being programmed while in the erase-suspend program mode will indicate logic "1" at the DQ2 bit. However, successive reads from the erase-suspended sector will cause DQ2 to toggle. 3. $\mathrm{DQ}_{0}$ and $\mathrm{DQ}_{1}$ are reserve pins for future use. $\mathrm{DQ}_{4}$ is for Fujitsu internal use only.

DQ7

## Data Polling

The MBM29F040C device features $\overline{\text { Data }}$ Polling as a method to indicate to the host that the Embedded Algorithms are in progress or completed. During the Embedded Program Algorithm an attempt to read the device will produce the compliment of the data last written to DQ7. Upon completion of the Embedded Program Algorithm, an attempt to read the device will produce the true data last written to DQ7. During the Embedded Erase Algorithm, an attempt to read the device will produce a " 0 " at the DQ7 output. Upon completion of the Embedded Erase Algorithm an attempt to read the device will produce a " 1 " at the DQ7 output. The flowchart for Data Polling (DQ7) is shown in Figure 15.

For chip erase, and sector erase the $\overline{\text { Data }}$ Polling is valid after the rising edge of the sixth $\overline{W E}$ pulse in the six write pulse sequence. For sector erase, the Data Polling is valid after the last rising edge of the sector erase WE pulse. Data Polling must be performed at sector address within any of the sectors being erased and not a protected sector. Otherwise, the status may not be valid. Once the Embedded Algorithm operation is close to being completed, the MBM29F040C data pins (DQ7) may change asynchronously while the output enable ( $\overline{\mathrm{OE}}$ ) is asserted low. This means that the device is driving status information on $\mathrm{DQ}_{7}$ at one instant of time and then that byte's valid data at the next instant of time. Depending on when the system samples the DQ7 output, it may read the status or valid data. Even if the device has completed the Embedded Algorithm operation and DQ7 has a valid data, the data outputs on $\mathrm{DQ}_{0}$ to $\mathrm{DQ}_{6}$ may be still invalid. The valid data on $\mathrm{DQ}_{0}$ to $\mathrm{DQ}_{7}$ will be read on the successive read attempts.

The Data Polling feature is only active during the Embedded Programming Algorithm, Embedded Erase Algorithm, or sector erase time-out. (See Table 6.)

See Figure 9 for the Data Polling timing specifications and diagrams.

## MBM29F040C-55/-70/-90

## DQ6

## Toggle Bit I

The MBM29F040C also features the "Toggle Bit l" as a method to indicate to the host system that the Embedded Algorithms are in progress or completed.

During an Embedded Program or Erase Algorithm cycle, successive attempts to read ( $\overline{\mathrm{OE}}$ toggling) data from the device will result in DQ6 toggling between one and zero. Once the Embedded Program or Erase Algorithm cycle is completed, DQ6 will stop toggling and valid data will be read on the next successive attempts. During programming, the Toggle Bit I is valid after the rising edge of the fourth $\overline{W E}$ pulse in the four write pulse sequence. For chip erase and sector erase, the Toggle Bit I is valid after the rising edge of the sixth WE pulse in the six write pulse sequence. The Toggle Bit I is active during the sector time out.
In programming, if the sector being written to is protected, the toggle bit will toggle for about $2 \mu \mathrm{~s}$ and then stop toggling without the data having changed. In erase, the device will erase all the selected sectors except for the ones that are protected. If all selected sectors are protected, the chip will toggle the toggle bit for about $100 \mu \mathrm{~s}$ and then drop back into read mode, having changed none of the data.
Either $\overline{\mathrm{CE}}$ or $\overline{\mathrm{OE}}$ toggling will cause the $\mathrm{DQ}_{6}$ to toggle. In addition, an Erase Suspend/Resume command will cause the DQ ${ }_{6}$ to toggle.

See Figure 10 for the Toggle Bit timing specifications and diagrams.

## DQ5

## Exceeded Timing Limits

DQ5 will indicate if the program or erase time has exceeded the specified limits (internal pulse count). Under these conditions DQ5 will produce a " 1 ". This is a failure condition which indicates that the program or erase cycle was not successfully completed. $\overline{\text { Data }}$ Polling $\mathrm{DQ}_{7}, \mathrm{DQ}_{6}$ is the only operating function of the device under this condition. The $\overline{\mathrm{CE}}$ circuit will partially power down the device under these conditions (to approximately 2 $\mathrm{mA})$. The $\overline{\mathrm{OE}}$ and $\overline{\mathrm{WE}}$ pins will control the output disable functions as described in Table 2.
The DQ5 failure condition may also appear if a user tries to program a non blank location without erasing. In this case the device locks out and never completes the Embedded Algorithm operation. Hence, the system never reads a valid data on DQ ${ }_{7}$ bit and $\mathrm{DQ}_{6}$ never stops toggling. Once the device has exceeded timing limits, the DQ5 bit will indicate a " 1 ." Please note that this is not a device failure condition since the device was incorrectly used. If this occurs, reset the device with command sequence.
DQ3

## Sector Erase Timer

After the completion of the initial sector erase command sequence the sector erase time-out will begin. $\mathrm{DQ}_{3}$ will remain low until the time-out is complete. Data Polling and Toggle Bit I are valid after the initial sector erase command sequence.
If $\overline{\text { Data }}$ Polling or the Toggle Bit I indicates the device has been written with a valid erase command. DQ3 may be used to determine if the sector erase timer window is still open. If $\mathrm{DQ}_{3}$ is high ("1") the internally controlled erase cycle has begun; attempts to write subsequent commands to the device will be ignored until the erase operation is completed as indicated by Data Polling or Toggle Bit I. If DQ ${ }_{3}$ is low (" 0 "), the device will accept additional sector erase commands. To insure the command has been accepted, the system software should check the status of $D Q_{3}$ prior to and following each subsequent sector erase command. If $D Q_{3}$ were high on the second status check, the command may not have been accepted.

Refer to Table 6: Hardware Sequence Flags.

## MBM29F040C-55/-70/-90

## DQ2

## Toggle Bit II

This Toggle Bit II, along with DQ6, can be used to determine whether the devices are in the Embedded Erase Algorithm or in Erase Suspend.

Successive reads from the erasing sector will cause $\mathrm{DQ}_{2}$ to toggle during the Embedded Erase Algorithm. If the devices are in the erase-suspended-read mode, successive reads from the erase-suspended sector will cause $\mathrm{DQ}_{2}$ to toggle. When the devices are in the erase-suspended-program mode, successive reads from the byte address of the non-erase suspended sector will indicate a logic " 1 " at the $\mathrm{DQ}_{2}$ bit.
$D Q_{6}$ is different from $D Q_{2}$ in that $\mathrm{DQ}_{6}$ toggles only when the standard program or Erase, or Erase Suspend Program operation is in progress. The behavior of these two status bits, along with that of $D Q_{7}$, is summarized as follows:

| Mode | $\mathbf{D Q}_{7}$ | $\mathbf{D Q}_{6}$ | $\mathbf{D Q}_{\mathbf{7}}$ |
| :--- | :---: | :---: | :---: |
| Program | $\overline{\mathrm{DQ}}_{7}$ | toggles | 1 |
| Erase | 0 | toggles | toggles |
| Erase Suspend Read <br> (Erase-Suspended Sector) <br> (Note 1) | 1 | 1 | toggles |
| Erase Suspend Program | $\overline{\mathrm{DQ}}_{7}$ (Note 2) | toggles | 1 (Note 2) |

Notes: 1 . These status flags apply when outputs are read from a sector that has been erase-suspended.
2. These status flags apply when outputs are read from the byte address of the non-erase suspended sector.

## Data Protection

The MBM29F040C is designed to offer protection against accidental erasure or programming caused by spurious system level signals that may exist during power transitions. During power up the device automatically resets the internal state machine in the Read mode. Also, with its control register architecture, alteration of the memory contents only occurs after successful completion of specific multi-bus cycle command sequences.
The device also incorporates several features to prevent inadvertent write cycles resulting form Vcc power-up and power-down transitions or system noise.

## Low Vcc Write Inhibit

To avoid initiation of a write cycle during Vcc power-up and power-down, a write cycle is locked out for Vcc less than 3.2 V (typically 3.7 V ). If $\mathrm{Vcc}<\mathrm{V}_{\mathrm{Lk}}$, the command register is disabled and all internal program/erase circuits are disabled. Under this condition the device will reset to the read mode. Subsequent writes will be ignored until the $\mathrm{V}_{\mathrm{cc}}$ level is greater than V цко. $^{\text {. }}$

## Write Pulse "Glitch" Protection

Noise pulses of less than 5 ns (typical) on $\overline{\mathrm{OE}}, \overline{\mathrm{CE}}$, or $\overline{\mathrm{WE}}$ will not initiate a write cycle.

## Logical Inhibit

Writing is inhibited by holding any one of $\overline{\mathrm{OE}}=\mathrm{V}_{\mathrm{IL}}, \overline{\mathrm{CE}}=\mathrm{V}_{\mathrm{IH}}$, or $\overline{\mathrm{WE}}=\mathrm{V}_{\mathrm{IH}}$. To initiate a write cycle $\overline{\mathrm{CE}}$ and $\overline{\mathrm{WE}}$ must be a logical zero while $\overline{\mathrm{OE}}$ is a logical one.

## MBM29F040C-55/-70-90

## Power-Up Write Inhibit

Power-up of the device with $\overline{\mathrm{WE}}=\overline{\mathrm{CE}}=\mathrm{V}_{\mathrm{IL}}$ and $\overline{\mathrm{OE}}=\mathrm{V}_{\mathbb{H}}$ will not accept commands on the rising edge of $\overline{\mathrm{WE}}$. The internal state machine is automatically reset to the read mode on power-up.

## MBM29F040C-55/-70/-90

## ABSOLUTE MAXIMUM RATINGS

| Stor | $-55^{\circ} \mathrm{C}$ to $+125^{\circ} \mathrm{C}$ |
| :---: | :---: |
| Ambient Temperature with Power Applied | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Voltage with Respect to Ground All pins except A9, OE (Note 1) | -2.0 V to +7.0 V |
| Vcc (Note 1) | -2.0 V to +7.0 V |
| As, $\overline{\mathrm{OE}}$ (Note 2) | -2.0 V to +13.5 V |

Notes: 1. Minimum DC voltage on input or I/O pins is -0.5 V . During voltage transitions, inputs may negative overshoot $\mathrm{V}_{\text {ss }}$ to -2.0 V for periods of up to 20 ns . Maximum DC voltage on output and I/O pins is Vcc +0.5 V . During voltage transitions, outputs may positive overshoot to $\mathrm{Vcc}+2.0 \mathrm{~V}$ for periods of up to 20 ns .
2. Minimum $D C$ input voltage on $\mathrm{A}_{9}$ and $\overline{\mathrm{OE}}$ pins are -0.5 V . During voltage transitions, $\mathrm{A}_{9}$ and $\overline{\mathrm{OE}} \mathrm{pins}$ may negative overshoot Vss to -2.0 V for periods of up to 20 ns. Maximum DC input voltage on A 9 and $\overline{\mathrm{OE}}$ pins are +13.5 V which may overshoot to 14.0 V for periods of up to 20 ns .

WARNING: Semiconductor devices can be permanently damaged by application of stress (voltage, current, temperature, etc.) in excess of absolute maximum ratings. Do not exceed these ratings.

## ■ RECOMMENDED OPERATING RANGES

WARNING: The recommended operating conditions are required in order to ensure normal operation of the semiconductor device. All of the device's electrical characteristics are warranted when the device is operated within these ranges.
Always use semiconductor devices within their recommended operating condition ranges. Operation outside these ranges may adversely affect reliability and could result in device failure.
No warranty is made with respect to uses, operating conditions, or combinations not represented on the data sheet. Users considering application outside the listed conditions are advised to contact their FUJITSU representatives beforehand.

© FUJITSU LIMITED Printed in Japan

All Rights Reserved.
The contents of this document are subject to change without notice. Customers are advised to consult with FUJITSU sales representatives before ordering.

The information and circuit diagrams in this document are presented as examples of semiconductor device applications, and are not intended to be incorporated in devices for actual use. Also, FUJITSU is unable to assume responsibility for infringement of any patent rights or other rights of third parties arising from the use of this information or circuit diagrams.

FUJITSU semiconductor devices are intended for use in standard applications (computers, office automation and other office equipment, industrial, communications, and measurement equipment, personal or household devices, etc.).

## CAUTION:

Customers considering the use of our products in special applications where failure or abnormal operation may directly affect human lives or cause physical injury or property damage, or where extremely high levels of reliability are demanded (such as aerospace systems, atomic energy controls, sea floor repeaters, vehicle operating controls, medical devices for life support, etc.) are requested to consult with FUJITSU sales representatives before such use. The company will not be responsible for damages arising from such use without prior approval.

Any semiconductor devices have an inhereut chance of failure. You must protect against injury, damage or loss from such failures by incorporating safety design measures into your facility and equipment such as redundancy, fire protection, and prevention of over-current levels and other abnormal operating conditions.

If any products described in this document represent goods or technologies subject to certain restrictions on export under the Foreign Exchange and Foreign Trade Law of Japan, the prior authorization by Japanese government will be required for export of those products from Japan.
