### 6.4 BASIC INTERVAL TIMER

The basic interval timer includes the following functions.

- A fixed frequency (2.048 kHz) can be output to the P23/BUZ pin for use in generating buzzer sounds and trimming system clock oscillator frequencies.
- The frequency divider can be cleared, so this watch can be started at 0 second.

Fig. 6-5 Timer/Event Counter Block Diagram

\* Instruction execution

**6.7 TIMER/PULSE GENERATOR**

  4. \*6 to \*10 indicate addressable areas.

(4) Description of the machine cycle column

S indicates the number of machine cycles required for skip operation by an instruction having skip function.

The S value varies as follows:

- When not skipped ..... S = 0
- When 1-byte or 2-byte instructions are skipped ..... S = 1
- When 3-byte instructions are skipped (BR !adder, CALL !adder instruction) ... S = 2

**Note** GETI instruction is skipped in one machine cycle.

One machine cycle is equal to one cycle (= t<sub>cy</sub>) of CPU clock φ and three time periods are available according to PCC setting.

- \* 1. Oscillator characteristics only. Refer to the description of AC characteristics for details of instruction execution time.
- 2. Time required for oscillation to become stabilized after VDD reaches MIN. of the oscillation voltage range or after STOP mode release.
- 3. When the oscillator frequency is 4.19 MHz < fx ≤ 5.0 MHz, PPC = 0011 should not be selected as the instruction execution time. If PCC = 0011 is selected, one machine cycle is less than 0.95 μs, and the specification MIN. value of 0.95 μs will not be achieved.

**Note** When the system clock oscillator is used, the following points should be noted concerning wiring in the section enclosed by dots, in order to prevent the effects of wiring capacitance, etc. ★

- Keep the wiring as short as possible.
- Do not cross any other signal lines, and keep clear of lines in which a high fluctuating current flows.
- Ensure that oscillator capacitor connection points are always at the same potential as VDD. Do not connect in a power supply pattern in which a high current flows.
- Do not take a signal from the oscillator.

The subsystem clock oscillator is designed to be a circuit with the low amplification factor to achieve low consumption current, with the result that it is more prone to misoperation due to noise than the main system clock oscillator. Therefore, when using the subsystem clock, special care is required for the wiring method.
