A27020 Series

Preliminary

256K X 8 OTP CMOS EPROM

Features

- 262,144 X 8 bit organization
- Programming voltage: 12.75V
- Access time: 55/70 ns (max.)
- Current: Operating: 30mA (max.) at 5MHz
Standby: 100μA (max.)
- All inputs and outputs are directly TTL-compatible
- Available in 32-pin DIP and 32-pin PLCC packages

General Description

The A27020 chip is a high-performance 2,097,152 bit one-time programmable read only memory (OTP EPROM) organized as 256K by 8 bits. The A27020 requires only 5V power supply in normal read mode

operation and any input signals are TTL levels. The A27020 is available in industry standard 32 pin dual-in-line and 32 pin PLCC packages.

Functional Description

Read Mode

The A27020 has two control functions, both of which must be logically active in order to obtain data at the outputs. $\overline{CE}$ is the power control and should be used for device selection. $\overline{OE}$ is the output control and should be used to data to the output pins, which is independent of device selection. Assuming that addresses are stable, address access time (t_{AA}) is equal to the delay from $\overline{CE}$ to output (t_{CE}). Data is available at the output after a delay (t_{OE}) from the falling edge of $\overline{OE}$, as long as $\overline{CE}$ has been low and the addresses have been stable for at least $t_{acc} - t_{OE}$.

Standby Mode

The A27020 has a standby mode which reduces the active current from 30mA to 100 μ A. The A27020 is placed in the standby mode by applying a CMOS high signal to $\overline{CE}$. When in the standby mode, the output are in a high impedance state, independent of the $\overline{OE}$.

Auto Identify Mode

Absolute Maximum Ratings*

Ambient Operating Temperature (T_A) -10°C to +85°C
 Storage Temperature Plastic Package (T_{STG})
 -55°C to 125°C
 Applied Input Voltage (V_i):
 All Pins Except A9, VPP and VCC
 -0.6V to VCC + 0.6V
 A9, VPP -0.6V to 13.5V
 VCC -0.6V to 7.0V
 Output Voltage (V_o) -0.6V to 7.0V (Note 1)

Notes:

1. During voltage transitions, the input may undershoot GND to -2.0V for periods less than 20 ns. Maximum DC voltage on input and I/O may overshoot to VCC + 2.0V for periods less than 20 ns.
2. When transitions, A9 and VPP may undershoot GND to -2.0V for periods less than 20 ns. Maximum DC input voltage on A9 and VPP is +13.5V which may overshoot to 14.0V for period less than 20 ns.

The auto identify mode allows the reading out of a binary code from a EPROM that will identify its manufacturer and type. This mode is intended for use by programming equipment for the purpose of automatically matching the device to be programmed with its corresponding programming algorithm.

To activate the mode, the programming equipment must apply 12.0V $\pm$ 0.5V on address line A9 of the A27020. Three identification code can be read from data output pin by toggling A0 and A1. The other addresses must be held at V_{IL} during this mode. Byte 0 (with A0 at V_{IL} , A1 at V_{IL}) represents the manufacturer code which is 37H. Byte 1 and Byte 2 represent the device code and continuation code, which is 64H and 7FH respectively. All identifiers for these codes will possess odd parity, with MSB (IO7) defined the parity bit.

*Comments

Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to this device. These are stress ratings only. Functional operation of this device at these or any other conditions above those indicated in the operational sections of this specification is not implied or intended. Exposure to the absolute maximum rating conditions for extended periods may affect device reliability.

Programming and Program Verify

The programming flowchart is shown in Page 10.

The A27020 is shipped with all bits being set to "1". Programming causes relevant bits to be changed to "0". The programming mode is started by setting VCC to +6.25V and VPP to +12.75V, while $\overline{CE}$ and $\overline{PGM}$ are at V_{IL} , and $\overline{OE}$ is at V_{IH} . Data to be programmed can be directly input in the 8 bit format through the data bus.

The write programming algorithm reduces programming time by using 100 μ s pulse followed by a byte verification to determine whether the byte has been successfully programmed. If the data does not pass the verification,

an additional pulse programming is applied for a maximum of 25 pulses. On completion of 1 byte programming and, The verified address is incremented. After the final address is completed, all bytes are verified again with VCC = 5.0 Volt.

Program Inhibit

This mode is used to program one of multiple A27020 whose $\overline{OE}$, $\overline{PGM}$, VPP, VCC, address bus and data bus are connected in parallel. When programming is performed, other A27020 can be inhibited from being programmed by setting their $\overline{CE}$ pins to V_{IH} .
