

FEATURES

- Fully Compliant with DECT Specifications
- Single IC DECT Radio
- Integrated UHF VCO (External Resonator)
- Integrated Synthesizer Supporting Extended Frequency Allocation
- Built-In Supply Regulation
- Direct VCO Modulation for DECT Transmit Path
- PLL-Based Demodulator
- Use with Low Cost Plastic Packaged SAW Filters
- Ultralow Power Design
- Operates from +3.0 V to +5.5 V Battery
- User-Selectable Power-Down Modes
- Small 48-Lead LQFP Package

APPLICATIONS

- DECT Cordless Telephones
- DECT-Based Wireless Local Loop Systems
- DECT-Based Wireless Data Systems

DESCRIPTION

The AD6411 provides the complete transmit and receive RF signal processing necessary to implement a digital wireless transceiver based on the Digital Enhanced Cordless Telecommunications (DECT) standard.

The AD6411's receive signal path consists of a mixer, IF amplifiers and PLL demodulator. The low noise, high intercept mixer is a development of the doubly-balanced Gilbert-Cell type. It has a nominal -16 dBm input-referred 1 dB compression point and a -8 dBm input referred third-order intercept. The limiter amplifier provides sufficient gain to drive the PLL demodulator, which provides selectable analog or sliced outputs. The RSSI output provides a voltage proportional to the receive signal strength. It measures nearly 100 dB IF signal strength range with 14 mV/dB gain scaling.

FUNCTIONAL BLOCK DIAGRAM

The transmit path accepts baseband data, which is filtered and applied to the VCO directly. The VCO operates at half the RF carrier frequency, and is doubled to avoid pulling due to leakage from the output.

An on-chip PLL frequency synthesizer provides channel selection. Operating modes are selected either through a serial bus or asynchronous control pins. This allows compatibility with most of the available DECT baseband controller ASICs.

The AD6411 is packaged in a 48-lead LQFP.

NOTES

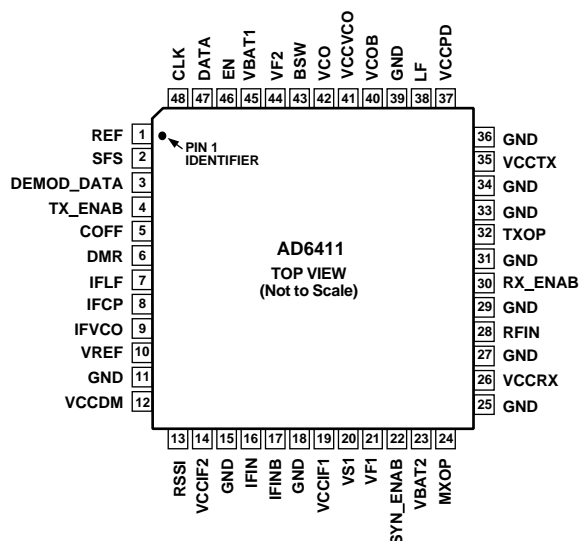

¹Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended rating conditions for extended periods may affect device reliability.

²Thermal Characteristics: 48-lead LQFP package: $\theta_{JA} = +126^{\circ}\text{C}/\text{W}$.

ORDERING GUIDE

Model	Temperature Range	Package Description	Package Option
AD6411AST	-25 $^{\circ}\text{C}$ to +85 $^{\circ}\text{C}$	48-Lead Plastic LQFP	ST-48

PIN CONFIGURATION 48-Lead LQFP (ST-48)

CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although the AD6411 features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

Figure 1. Functional Block Diagram

PRODUCT OVERVIEW

The AD6411 provides most of the active circuitry required to realize a complete low power DECT transceiver.

Figure 1 shows the main sections of the AD6411. It consists, in the receive path, of a UHF mixer and two-stage IF strip with integrated demodulator and data slicer. The transmit path consists of a VCO, frequency doubler and buffer amplifier.

Channel selection is performed by an on-chip PLL synthesizer. All AD6411 operating modes can be controlled by parallel control inputs or the serial interface.

Receive Mixer

The UHF mixer is an improved Gilbert-cell design. The dynamic range at the input of the mixer is determined, at the upper end, by the maximum input signal level of -16 dBm in $50\ \Omega$ at RFIN up to which the mixer remains linear and a valid RSSI signal is provided and, at the lower end, by the noise level.

The local oscillator input of the receive mixer is internally provided by the LO, which is obtained by doubling the on-chip VCO frequency.

The output of the mixer is single-ended. The nominal conversion gain is specified for operation into a 110.592 MHz or 112.32 MHz SAW IF DECT bandpass filter. The power gain of 17 dB is measured between the mixer input and the input of this filter.

IF Circuits and Demodulator

Demodulation is achieved via a PLL. This is shown in detail in Figure 2. An external manufacturing trim is required to achieve the required level of frequency accuracy. The approach is to adjust the capacitor TC1 (with the presence of an unmodulated carrier) such that the dc level at Pin 3 (DEMODO_DATA) is equal to the voltage on the external reference pin VREF.

Two demodulation modes are supported. In one mode any frequency offset due to reference drift or frequency offsets on the incoming carrier are propagated to the output (referred to as “Normal” demodulation). The other method is to use a feature of the DECT system that enables a secondary compensation circuit to track out frequency offsets (“S-field sampling,” which is enabled by the pin SFS—active high together with the configuration bit SFM set over the serial interface).

Figure 2. PLL Demodulator Block Diagram

The block diagram shows the principle of operation of these two modes together with the internal switch settings as shown in Figure 2.

Table I. Supported Demodulation Modes

Mode	SW1	SW2	SW3	Comment
Prior to RX SFS = Don't Care SFM = 0	Open	Closed	Closed	Precharge Loop Filter and C Offset Capacitor
Normal Demod – Active RX SFS = Don't Care SFM = 0	Open	Closed	Open	Use Temperature Compensated Reference Voltage
S-Field Sample SFS = 1 SFM = 1	Closed	Open	Open	
S-Field Hold SFS = 0 SFM = 1	Open	Open	Open	

An important consideration in normal demodulation mode is any drift after the initial setup of the VCO. One mechanism is the Capacitance vs. Temperature coefficient of the external varactor. This has a known characteristic which is compensated by an internal reference voltage generation circuit.

UHF VCO

A single UHF VCO oscillator is provided operating at one-half the required frequency. Therefore, in transmit mode the oscillator operates from (approximately) 940 MHz to 950 MHz, and in receive mode the oscillator operates from (approximately) 884 MHz–895 MHz. This requires a switched resonator design, and band switch control is provided by the AD6411.

A balanced oscillator configuration is used which has the advantages of rejection of common-mode interference and noise, and less coupling to and from other parts of the IC and radio.

Transmit Functions

The DECT transmit function is achieved by direct modulation of the UHF VCO operating at half the final transmit output frequency. An on-chip doubler converts this to the final carrier frequency. In this mode the synthesizer is set to a high impedance mode i.e., “fly-wheeled.” The drift is sufficiently low for both single-slot and double-slot transmit operation.

Synthesizer and LO Functions

A complete synthesizer is implemented on the IC that is capable of generating all the required DECT channel allocations (including the extended DECT bands). This synthesizer can use reference frequencies of either 13.824 MHz or 10.368 MHz, controlled by the RD bit in the control register.

Synthesizer Programming

The required channels are programmed by setting the RD bit in the control register to the correct value, then programming the A and M Counters as shown below through the serial interface.

Transmit

DECT Channel	A Counter	M Counter	Frequency/MHz
9	1	34	1881.792
8	2	34	1883.520
7	3	34	1885.248
6	4	34	1886.976
5	5	34	1888.704
4	6	34	1890.432
3	7	34	1892.160
2	8	34	1893.888
1	9	34	1893.888
0	10	34	1897.344

The A Counter range is 0–31, allowing the AD6411 to be used in the extended DECT bands, up to the following maximum frequency:

A Counter	M Counter	Frequency/MHz
31	34	1933.632

Receive (Local Oscillator Frequency)

Main values are shown for a 110.592 MHz IF frequency. Values in parentheses are for the 112.32 MHz.

DECT Channel	A Counter	M Counter	Frequency/MHz
9	1 (0)	32	1771.200 (1769.472)
8	2 (1)	32	1772.928 (1771.200)
7	3 (2)	32	1774.656 (1772.928)
6	4 (3)	32	1776.384 (1774.656)
5	5 (4)	32	1778.112 (1776.384)
4	6 (5)	32	1779.840 (1778.112)
3	7 (6)	32	1781.568 (1779.840)
2	8 (7)	32	1783.296 (1781.568)
1	9 (8)	32	1785.024 (1783.296)
0	10 (9)	32	1786.752 (1785.024)

Serial Interface

The IC operating modes can be controlled via the 3-wire serial interface or via the three external control lines provided (TX_ENAB, RX_ENAB, SYN_ENAB). The three external control lines allow mode control of the IC if the baseband controller cannot access the serial interface between slots. In either case the 3-wire serial interface is used to program the channel number. Detailed below is the register setup and the serial interface operation.

The serial interface consists of a 16-bit shift register and two registers for configuration of the IC and mode control. This allows mode control of the IC with a single 16-bit write. DATA is the serial data input (data MSB first), CLK is the shift register clock (positive edge trigger), EN (positive edge trigger) is the serial interface enable. All internal register values are retained when sections of the IC are powered down. Figure 3 shows the timing diagram for the serial interface.

Figure 3. Serial Interface Timing Diagram

Parameter	Symbol	Typ	Unit
Maximum Serial Clock Frequency	f_clk	13.824	MHz
Serial Data Set Up Time	t_dst	8	ns
Serial Data Hold Time	t_dhd	8	ns
Enable Set Up to Clock High	t_hen	10	ns
Clock Low to Enable Low	t_den	5	ns

The Least Significant Bit of the serial control word selects either the “one-time setup” register or the operating mode register, with the remaining 15 bits as data. Table II below details the internal IC register mapping.

Table II. Register Mapping

Address (D0)	Function	Comments
0	One-Time IC Setup	See Table III
1	IC Operating Mode	See Table IV

AD6411 INITIAL SETUP

On power-up the state of the IC is *not* defined. A one-time setup register must be loaded through the serial interface port, and is selected when the LSB of the serial word is 0. After this one-time setup, a single serial word controls operation of the IC.

Table III. One-Time IC Setup Register

D7	D6	D5	D4	D3	D2	D1	D0
DMOD	DIV	CP	TX BUF	UHF VCO	BSW	REGS	1

The operating mode register, loaded through the serial port when the LSB is “1,” allows any circuit block to be independently powered on or off. This can be bypassed to enable mode control of the IC via the three external control lines. Transitions between major DECT modes can be made with a single word program (including channel change) when using the serial interface only. Table V defines the bit status for the various IC operating modes when used with the serial interface only.

Table V. Bit Status for the Different Operating Modes

Data Bits (D9 . . . D0) Operating Mode Register	Function	Comments
00 0000 0101	All Off Mode	All Circuits Off
00 0000 0111	Stand-By Mode	Regulators On
00 0111 1111	Prior to TX Slot	VCO, TX Buffer, Dividers, Charge Pump, Regulators Active, VREF (1.4 V) Active
00 0101 1111	Active TX Slot	VCO, TX Buffer, Dividers, Regulator Circuits Active, VREF (1.4 V) Active ¹
00 1110 1011	Prior to RX Slot	VCO ² , Dividers, Charge Pump, Regulators, Demodulator Precharge Circuits Active, VREF (1.4 V) Active
11 1100 1011	Active RX Slot	RX Mixer, VCO ² , Dividers, Regulators, Demodulator, Receive Strip Circuits Active, VREF (1.4 V) Active

NOTES

¹Alternatively it may be possible to power-down the dividers in an active transmit slot depending on the effect of thermal transients on VCO pulling. In this mode the dividers are biased but inactive. This can also be implemented when external control lines are used with bits TXM, RXM1, RXM0.

²Band switch output is determined by the status of BSW. Band switch output is Low when BSW is high, high when BSW is low. In Table V, band switch output is high for AcRx and PrRx slots, otherwise it is low.

CHANNEL SELECTION/FREQUENCY CONTROL

The M0 and A4–A0 bits in the operating mode register control the channel selection for the AD6411 synthesizer. The M0 bit selects the M Counter division ratio.

M0: M Counter Divide Ratio

M0	Function
0	M Divide Ratio 32
1	M Divide Ratio 34

The A4 through A0 bits control the A counter division ratio, and control the channel selection. Refer to the section of this data sheet on Synthesizer Programming for a mapping of channel frequency to synthesizer divider words.

A4–A0: A Counter Division Ratio

“A”	A4	A3	A2	A1	A0
0	0	0	0	0	0
1	0	0	0	0	1
2	0	0	0	1	0
3	0	0	0	1	1
–	–	–	–	–	–
30	1	1	1	1	0
31	1	1	1	1	1

ANALOG/RF INTERFACE DETAILS

The AD6411 is an advanced 1.9 GHz radio transceiver circuit and requires careful attention to the selection of external components. The AD6411 is readily capable of performance that meets the ETS-300-176-1 (formerly TBR06) DECT radio specifications. This section of the data sheet will describe suggestions for external componentry that will allow the design of a complete DECT RF transceiver.

Low Noise Amplifier

An external LNA is required to meet the RF leakage specifications in ETS-300-176-1. The following circuit, based on a Siemens BFP405 discrete transistor, is representative of a suitable LNA. The SC1.89 SAW filter removes images prior to the down converter. The filter is matched to the AD6411 input with a printed inductor and fixed capacitor. Complete details of the circuit, with transmission-line dimensions, can be found in Siemens Application Note No. 020.

Figure 4. LNA circuit

AD6411

UHF VCO Tank Circuit

The UHF VCO is probably the most critical part of an AD6411-based DECT radio. The design shown in Figure 5 uses a printed inductor, a BBY53 (or equivalent) common-cathode dual varactor, and a PIN-diode (BAR63-03W or equivalent) band switch to cover the DECT band. The capacitance added to the tank circuit by the PIN-diode is needed to switch the VCO to the DECT receive band. It is switched out of the circuit in the transmit mode, in which the VCO is directly modulated by baseband transmit data. With this scheme, no manufacturing trim is needed to tune the VCO to the DECT band. Tank component values will need slight modification to cover the “extended DECT” frequency bands. The dimensions of tank inductor L1 will depend on the circuit board material and thickness used. Contact Analog Devices for assistance on UHF tank inductor layout.

Figure 5. UHF VCO Circuit

Power Management

The AD6411 reduces the external components needed for power management in a DECT radio by integrating voltage regulators on-chip. The circuit can therefore operate directly from a 3.0 V to 5.5 V unregulated battery supply.

There are two regulators. The first, VS1 (Pins 20, 21 and 23), uses an external BCW68F (or similar) PNP pass transistor to provide a regulated 2.75 V nominal supply voltage to most of the AD6411 circuitry. The second regulator, VS2 (Pins 41, 44, and 45), is intended to provide the regulated voltage to the UHF VCO section and should not be used for other circuitry.

PASS TRANSISTORS: BCW68F OR EQUIVALENT

Figure 6. Voltage Regulator Circuitry

Transmit/Receive Switching

Since the same antenna is used for both transmit and receive, a switch consisting of PIN diodes and printed transmission lines is used to disconnect the receive path from the antenna during transmit periods. A suggested circuit is shown in Figure 7. Complete details can be found in Siemens Application Note No. 007.
