LINEAR TECHNOLOGY

LTC4059

900mA Linear Li-Ion Battery Charger with Thermal Regulation in 2 × 2 DFN

FEATURES

- **Programmable Charge Current Up to 900mA with ±5% Accuracy**
- **Charge Current Monitor Output for Charge Termination***
- **Constant-Current/Constant-Voltage Operation with Thermal Regulation to Maximize Charging Rate Without Risk of Overheating***
- Constant-Current Source Mode for Charging Nickel Batteries
- No External MOSFET, Sense Resistor or Blocking Diode Required
- Operating Supply Voltage from 3.75V to 8V
- Charges Single Cell Li-Ion Batteries Directly from USB Port
- Preset 4.2V Charge Voltage with 0.6% Accuracy
- 10µA Supply Current in Shutdown Mode
- Tiny 6-Lead (2mm × 2mm) DFN Package

APPLICATIONS

- Wireless PDAs
- Cellular Phones
- Portable Electronics
- Wireless Headsets
- Digital Cameras

DESCRIPTION

The LTC®4059 is a constant-current/constant-voltage linear charger for single cell lithium-ion batteries. Its 2mm × 2mm DFN package and low external component count make the LTC4059 especially well suited for portable applications. Furthermore, the LTC4059 is designed to work within USB power specifications.

No external sense resistor, MOSFET or blocking diode is required. Thermal feedback regulates the charge current to limit the die temperature during high power operation or high ambient thermal conditions. The charge voltage is fixed at 4.2V and the charge current can be programmed with a resistor.

When the input supply (wall adapter or USB supply) is removed, the LTC4059 automatically enters a low current state, dropping the battery current drain to less than 1µA. With power applied, the LTC4059 can be put into shutdown mode, reducing the supply current to 10µA.

The LTC4059 can also be used as a constant current source to charge Nickel cells. Other features include undervoltage lockout protection and a current monitor pin which can indicate when to terminate a charge cycle.
The LTC4059 is available in a 6-lead, low profile (0.8mm) 2mm × 2mm DFN package.

PIN FUNCTIONS

GND (Pins 1, 7): Ground/Exposed Pad. The exposed package pad is ground and must be soldered to the PC board for maximum heat transfer.

Li̅C̅C̅ (Pin 2): Li-Ion/Constant Current Input Pin. Pulling this pin above $V_{Li\overline{CC}}$ disables voltage mode thereby providing a constant current to the BAT pin. This feature is useful for charging Nickel chemistry batteries. Tie to GND if unused.

BAT (Pin 3): Charge Current Output. Provides charge current to the battery and regulates the final float voltage to 4.2V. An internal precision resistor divider from this pin sets this float voltage and is disconnected in shutdown mode.

V_{CC} (Pin 4): Positive Input Supply Voltage. This pin provides power to the charger. V_{CC} can range from 3.75V to 8V. This pin should be bypassed with at least a 1μF capacitor. When V_{CC} is within 35mV of the BAT pin

voltage, the LTC4059 enters shutdown mode, dropping I_{BAT} to less than 4μA.

PROG (Pin 5): Charge Current Program and Charge Current Monitor Pin. Connecting a 1% resistor, R_{PROG}, to ground programs the charge current. When charging in constant-current mode, this pin servos to 1.21V. In all modes, the voltage on this pin can be used to measure the charge current using the following formula:

$$I_{BAT} = \frac{V_{PROG}}{R_{PROG}} \bullet 1000$$

E̅N̅ (Pin 6): Enable Input Pin. Pulling this pin above the manual shutdown threshold (V_{MS} is typically 0.92V) puts the LTC4059 in shutdown mode, thus terminating a charge cycle. In shutdown mode, the LTC4059 has less than 30μA supply current and less than 1μA battery drain current. Enable is the default state, but the pin should be tied to GND if unused.

BLOCK DIAGRAM

Figure 1

OPERATION

The LTC4059 is a linear battery charger designed primarily for charging single cell lithium-ion batteries. Featuring an internal P-channel power MOSFET, the charger uses a constant-current/constant-voltage charge algorithm with programmable current. Charge current can be programmed up to 900mA with a final float voltage accuracy of ±0.6%. No blocking diode or external sense resistor is required; thus, the basic charger circuit requires only two external components. The Li|CC pin disables constant-voltage operation and turns the LTC4059 into a precision current source capable of charging Nickel chemistry batteries. Furthermore, the LTC4059 is designed to operate from a USB power source.

An internal thermal limit reduces the programmed charge current if the die temperature attempts to rise above a preset value of approximately 115°C. This feature protects the LTC4059 from excessive temperature, and allows the user to push the limits of the power handling capability of a given circuit board without risk of damaging the LTC4059 or external components. Another benefit of the LTC4059

thermal limit is that charge current can be set according to typical, not worst-case, ambient temperatures for a given application with the assurance that the charger will automatically reduce the current in worst-case conditions.

The charge cycle begins when the voltage at the V_{CC} pin rises approximately 150mV above the BAT pin voltage, a 1% program resistor is connected from the PROG pin to ground, and the $\overline{EN}$ pin is pulled below the shutdown threshold (typically 0.85V).

If the BAT pin voltage is below 4.2V (or the Li|CC pin is pulled above $V_{Li|\overline{CC}}$) the LTC4059 will charge the battery with the programmed current. This is constant-current mode. When the BAT pin approaches the final float voltage (4.2V), the LTC4059 enters constant-voltage mode and the charge current begins to decrease.

To terminate the charge cycle the $\overline{EN}$ should be pulled above the shutdown threshold. Alternatively, reducing the input voltage below the BAT pin voltage will also terminate the charge cycle.

APPLICATIONS INFORMATION

Programming Charge Current

The charge current is programmed using a single resistor from the PROG pin to ground. The battery charge current is 1000 times the current out of the PROG pin. The program resistor and the charge current are calculated using the following equations:

$$R_{PROG} = 1000 \bullet \frac{1.21V}{I_{CHG}}, \ I_{CHG} = 1000 \bullet \frac{1.21V}{R_{PROG}}$$

The charge current out of the BAT pin can be determined at any time by monitoring the PROG pin voltage and using the following equation:

$$I_{BAT} = \frac{V_{PROG}}{R_{PROG}} \bullet 1000$$

Undervoltage Lockout (UVLO)

An internal undervoltage lockout circuit monitors the input voltage and keeps the charger in undervoltage lockout until V_{CC} rises approximately 150mV above the BAT pin voltage. The UVLO circuit has a built-in hysteresis of 115mV. If the BAT pin voltage is below approximately 2.75V, then the charger will remain in undervoltage lockout until V_{CC} rises above approximately 3V. During undervoltage lockout conditions, maximum battery drain current is 4μA.

Shutdown Mode

Charging can be terminated by pulling the $\overline{EN}$ pin above the shutdown threshold (approximately 0.92V). In shutdown mode, the battery drain current is reduced to less than 1μA and the supply current to 10μA.

APPLICATIONS INFORMATION

USB and Wall Adapter Power

Although the LTC4059 allows charging from a USB port, a wall adapter can also be used to charge Li-Ion batteries. Figure 2 shows an example of how to combine wall adapter and USB power inputs. A P-channel MOSFET, MP1, is used to prevent back conducting into the USB port when a wall adapter is present and Schottky diode, D1, is used to prevent USB power loss through the 1k pull-down resistor.

Typically a wall adapter can supply significantly more current than the 500mA limited USB port. Therefore, an N-channel MOSFET, MN1, and an extra program resistor are used to increase the charge current to 850mA when the wall adapter is present.

Figure 2. Combining Wall Adapter and USB Power

Constant Current/Constant Voltage/ Constant Temperature

The LTC4059 uses a unique architecture to charge a battery in a constant-current, constant-voltage and constant-temperature fashion. Figure 1 shows a simplified block diagram of the LTC4059. Three of the amplifier feedback loops shown control the constant-current, CA, constant-voltage, VA, and constant-temperature, TA modes. A fourth amplifier feedback loop, MA, is used to increase the output impedance of the current source pair, M1 and M2 (note that M1 is the internal P-channel power MOSFET). It ensures that the drain current of M1 is exactly 1000 times greater than the drain current of M2.

Amplifiers CA and VA are used in separate feedback loops to force the charger into constant-current or voltage mode, respectively. Diodes D1 and D2 provide priority to either the constant-current or constant-voltage loop;

whichever is trying to reduce the charge current the most. The output of the other amplifier saturates low which effectively removes its loop from the system. When in constant-current mode, CA servos the voltage at the PROG pin to be 1.21V. VA servos its inverting input to precisely 1.21V when in constant-voltage mode and the internal resistor divider made up of R1 and R2 ensures that the battery voltage is maintained at 4.2V. The PROG pin voltage gives an indication of the charge current during constant-voltage mode as discussed in the Programming Charge Current section.

Transconductance amplifier, TA, limits the die temperature to approximately 115°C when in constant-temperature mode. TA acts in conjunction with the constant-current loop. When the die temperature exceeds approximately 115°C, TA sources current through R3. This causes CA to reduce the charge current until the PROG pin voltage plus the voltage across R3 equals 1.21V. Diode D3 ensures that TA does not affect the charge current when the die temperature is below approximately 115°C. The PROG pin voltage continues to give an indication of the charge current.

In typical operation, the charge cycle begins in constant-current mode with the current delivered to the battery equal to $1210V/R_{PROG}$. If the power dissipation of the LTC4059 results in the junction temperature approaching 115°C, the amplifier (TA) will begin decreasing the charge current to limit the die temperature to approximately 115°C. As the battery voltage rises, the LTC4059 either returns to constant-current mode or enters constant-voltage mode straight from constant-temperature mode. Regardless of mode, the voltage at the PROG pin is proportional to the current delivered to the battery.

Power Dissipation

The conditions that cause the LTC4059 to reduce charge current through thermal feedback can be approximated by considering the power dissipated in the IC. For high charge currents, the LTC4059 power dissipation is approximately:

$$P_D = (V_{CC} - V_{BAT}) \bullet I_{BAT}$$

where P_D is the power dissipated, V_{CC} is the input supply voltage, V_{BAT} is the battery voltage and I_{BAT} is the charge

APPLICATIONS INFORMATION

current. It is not necessary to perform any worst-case power dissipation scenarios because the LTC4059 will automatically reduce the charge current to maintain the die temperature at approximately 115°C. However, the approximate ambient temperature at which the thermal feedback begins to protect the IC is:

$$T_A = 115°C - P_D\theta_{JA}$$

$$T_A = 115°C - (V_{CC} - V_{BAT}) \bullet I_{BAT} \bullet \theta_{JA}$$

Example: Consider an LTC4059 operating from a 5V wall adapter providing 900mA to a 3.7V Li-Ion battery. The ambient temperature above which the LTC4059 will begin to reduce the 900mA charge current is approximately:

$$T_A = 115°C - (5V - 3.7V) \bullet (900mA) \bullet 50°C/W$$

$$T_A = 115°C - 1.17W \bullet 50°C/W = 115°C - 59°C$$

$$T_A = 56°C$$

The LTC4059 can be used above 56°C, but the charge current will be reduced from 900mA. The approximate current at a given ambient temperature can be calculated:

$$I_{BAT} = \frac{115°C - T_A}{(V_{CC} - V_{BAT}) \bullet \theta_{JA}}$$

Using the previous example with an ambient temperature of 65°C, the charge current will be reduced to approximately:

$$I_{BAT} = \frac{115°C - 65°C}{(5V - 3.7V) \bullet 50°C/W} = \frac{50°C}{65°C/A}$$

$$I_{BAT} = 770mA$$

Furthermore, the voltage at the PROG pin will change proportionally with the charge current as discussed in the Programming Charge Current section.

It is important to remember that LTC4059 applications do not need to be designed for worst-case thermal conditions since the IC will automatically reduce power dissipation when the junction temperature reaches approximately 115°C.

Board Layout Considerations

In order to be able to deliver maximum charge current under all conditions, it is critical that the exposed metal pad on the backside of the LTC4059 package is soldered to the PC board ground. Correctly soldered to a 2500mm^2 double sided 1oz copper board the LTC4059 has a thermal resistance of approximately 60°C/W. Failure to make thermal contact between the exposed pad on the backside of the package and the copper board will result in thermal resistances far greater than 60°C/W. As an example, a correctly soldered LTC4059 can deliver over 900mA to a battery from a 5V supply at room temperature. Without a backside thermal connection, this number could drop to less than 500mA.

Stability Considerations

The LTC4059 contains two control loops: constant voltage and constant current. The constant-voltage loop is stable without any compensation when a battery is connected with low impedance leads. Excessive lead length, however, may add enough series inductance to require a bypass capacitor of at least 1μF from BAT to GND. Furthermore, a 4.7μF capacitor with a 0.2Ω to 1Ω series resistor from BAT to GND is required to keep ripple voltage low when the battery is disconnected.

High value capacitors with very low ESR (especially ceramic) reduce the constant-voltage loop phase margin. Ceramic capacitors up to 22μF may be used in parallel with a battery, but larger ceramics should be decoupled with 0.2Ω to 1Ω of series resistance.

In constant-current mode, the PROG pin is in the feedback loop, not the battery. Because of the additional pole created by PROG pin capacitance, capacitance on this pin must be kept to a minimum. With no additional capacitance on the PROG pin, the charger is stable with program resistor values as high as 12k. However, additional capacitance on this node reduces the maximum allowed program resistor. The pole frequency at the PROG pin should be kept above 500kHz. Therefore, if the PROG pin is loaded

APPLICATIONS INFORMATION

with a capacitance, C_{PROG}, the following equation should be used to calculate the maximum resistance value for R_{PROG}:

$$R_{PROG} \leq \frac{1}{2\pi \cdot 5 \cdot 10^5 \cdot C_{PROG}}$$

Average, rather than instantaneous, battery current may be of interest to the user. For example, if a switching power supply operating in low current mode is connected in parallel with the battery, the average current being pulled out of the BAT pin is typically of more interest than the instantaneous current pulses. In such a case, a simple RC filter can be used on the PROG pin to measure the average

battery current as shown in Figure 3. A 20k resistor has been added between the PROG pin and the filter capacitor to ensure stability.

V_CC Bypass Capacitor

Many types of capacitors can be used for input bypassing; however, caution must be exercised when using multilayer ceramic capacitors. Because of the self-resonant and high Q characteristics of some types of ceramic capacitors, high voltage transients can be generated under some start-up conditions, such as connecting the charger input to a live power source. For more information, refer to Application Note 88.
