4-Mbit (128K x 32) Pipelined Sync SRAM

Features

- **Registered inputs and outputs for pipelined operation**
- **128K × 32 common I/O architecture**
- **3.3V core power supply**
- **2.5V / 3.3V I/O operation**
- **Fast clock-to-output times**
  - **— 2.6 ns (for 250-MHz device)**
  - **— 2.8 ns (for 200-MHz device)**
  - **— 3.5 ns (for 166-MHz device)**
  - **— 4.0 ns (for 133-MHz device)**
- **Provide high-performance 3-1-1-1 access rate**
- **User-selectable burst counter supporting Intel® Pentium® interleaved or linear burst sequences**
- **Separate processor and controller address strobes**
- **Synchronous self-timed writes**
- **Asynchronous output enable**
- **Lead-Free 100-pin TQFP and 119-ball BGA packages**
- **"ZZ" Sleep Mode Option**

Functional Description[1]

The CY7C1339G SRAM integrates 131,072 x 32 SRAM cells with advanced synchronous peripheral circuitry and a two-bit counter for internal burst operation. All synchronous inputs are gated by registers controlled by a positive-edge-triggered Clock Input (CLK). The synchronous inputs include all addresses, all data inputs, address-pipelining Chip Enable ($\overline{CE_1}$), depth-expansion Chip Enables (CE_2 and $\overline{CE_3}$), Burst Control inputs ($\overline{ADSC}$, $\overline{ADSP}$, and $\overline{ADV}$), Write Enables ($\overline{BW}_{[A:D]}$, and $\overline{BWE}$), and Global Write ($\overline{GW}$). Asynchronous inputs include the Output Enable ($\overline{OE}$) and the ZZ pin.

Addresses and chip enables are registered at rising edge of clock when either Address Strobe Processor ($\overline{ADSP}$) or Address Strobe Controller ($\overline{ADSC}$) are active. Subsequent burst addresses can be internally generated as controlled by the Advance pin ($\overline{ADV}$).

Address, data inputs, and write controls are registered on-chip to initiate a self-timed Write cycle. This part supports Byte Write operations (see Pin Descriptions and Truth Table for further details). Write cycles can be one to four bytes wide as controlled by the byte write control inputs. $\overline{GW}$ when active LOW causes all bytes to be written.

The CY7C1339G operates from a +3.3V core power supply while all outputs may operate with either a +2.5 or +3.3V supply. All inputs and outputs are JEDEC-standard JESD8-5-compatible.

Pin Definitions

Name	I/O	Description
A_0, A_1, A	Input-Synchronous	**Address Inputs used to select one of the 128K address locations**. Sampled at the rising edge of the CLK if $\overline{ADSP}$ or $\overline{ADSC}$ is active LOW, and $\overline{CE}_1$, CE_2, and $\overline{CE}_3$ are sampled active. A1, A0 are fed to the two-bit counter.
$\overline{BW}_A, \overline{BW}_B$ $\overline{BW}_C, \overline{BW}_D$	Input-Synchronous	**Byte Write Select Inputs, active LOW**. Qualified with $\overline{BWE}$ to conduct byte writes to the SRAM. Sampled on the rising edge of CLK·
$\overline{GW}$	Input-Synchronous	**Global Write Enable Input, active LOW**. When asserted LOW on the rising edge of CLK, a global write is conducted (ALL bytes are written, regardless of the values on $BW_{[A:D]}$ and $\overline{BWE}$).
$\overline{BWE}$	Input-Synchronous	**Byte Write Enable Input, active LOW**. Sampled on the rising edge of CLK. This signal must be asserted LOW to conduct a byte write.
CLK	Input-Clock	**Clock Input**. Used to capture all synchronous inputs to the device. Also used to increment the burst counter when $\overline{ADV}$ is asserted LOW, during a burst operation.
$\overline{CE}_1$	Input-Synchronous	**Chip Enable 1 Input, active LOW**. Sampled on the rising edge of CLK. Used in conjunction with CE_2 and $\overline{CE}_3$ to select/deselect the device. $\overline{ADSP}$ is ignored if $\overline{CE}_1$ is HIGH. $\overline{CE}_1$ is sampled only when a new external address is loaded.
CE_2	Input-Synchronous	**Chip Enable 2 Input, active HIGH**. Sampled on the rising edge of CLK. Used in conjunction with $\overline{CE}_1$ and $\overline{CE}_3$ to select/deselect the device. CE_2 is sampled only when a new external address is loaded.
$\overline{CE}_3$	Input-Synchronous	**Chip Enable 3 Input, active LOW**. Sampled on the rising edge of CLK. Used in conjunction with $\overline{CE}_1$ and CE_2 to select/deselect the device. $\overline{CE}_3$ is sampled only when a new external address is loaded. Not connected for BGA. Where referenced, $\overline{CE}_3$ is assumed active throughout this document for BGA.
$\overline{OE}$	Input-Asynchronous	**Output Enable, asynchronous input, active LOW**. Controls the direction of the I/O pins. When LOW, the I/O pins behave as outputs. When deasserted HIGH, I/O pins are tri-stated, and act as input data pins. $\overline{OE}$ is masked during the first clock of a read cycle when emerging from a deselected state.

Pin Definitions (continued)

Name	I/O	Description
$\overline{ADV}$	Input-Synchronous	**Advance Input signal, sampled on the rising edge of CLK, active LOW**. When asserted, it automatically increments the address in a burst cycle.
$\overline{ADSP}$	Input-Synchronous	**Address Strobe from Processor, sampled on the rising edge of CLK, active LOW**. When asserted LOW, addresses presented to the device are captured in the address registers. A1, A0 are also loaded into the burst counter. When ADSP and ADSC are both asserted, only ADSP is recognized. ASDP is ignored when $\overline{CE}_1$ is deasserted HIGH.
$\overline{ADSC}$	Input-Synchronous	**Address Strobe from Controller, sampled on the rising edge of CLK, active LOW**. When asserted LOW, addresses presented to the device are captured in the address registers. A1, A0 are also loaded into the burst counter. When ADSP and ADSC are both asserted, only ADSP is recognized.
ZZ	Input-Asynchronous	**ZZ "sleep" Input, active HIGH**. When asserted HIGH places the device in a non-time-critical "sleep" condition with data integrity preserved. For normal operation, this pin has to be LOW or left floating. ZZ pin has an internal pull-down.
DQs	I/O-Synchronous	**Bidirectional Data I/O lines**. As inputs, they feed into an on-chip data register that is triggered by the rising edge of CLK. As outputs, they deliver the data contained in the memory location specified by the addresses presented during the previous clock rise of the read cycle. The direction of the pins is controlled by $\overline{OE}$. When $\overline{OE}$ is asserted LOW, the pins behave as outputs. When HIGH, DQs are placed in a tri-state condition.
V_{DD}	Power Supply	**Power supply inputs to the core of the device**.
V_{SS}	Ground	**Ground for the core of the device**.
V_{DDQ}	I/O Power Supply	**Power supply for the I/O circuitry**.
V_{SSQ}	I/O Ground	**Ground for the I/O circuitry**.
MODE	Input-Static	**Selects Burst Order**. When tied to GND selects linear burst sequence. When tied to V_{DD} or left floating selects interleaved burst sequence. This is a strap pin and should remain static during device operation. Mode Pin has an internal pull-up.
NC		**No Connects**. Not internally connected to the die

Functional Overview

All synchronous inputs pass through input registers controlled by the rising edge of the clock. All data outputs pass through output registers controlled by the rising edge of the clock. Maximum access delay from the clock rise (t_{CO}) is 2.6 ns (250-MHz device).

The CY7C1339G supports secondary cache in systems utilizing either a linear or interleaved burst sequence. The interleaved burst order supports Pentium and i486™ processors. The linear burst sequence is suited for processors that utilize a linear burst sequence. The burst order is user selectable, and is determined by sampling the MODE input. Accesses can be initiated with either the Processor Address Strobe ($\overline{ADSP}$) or the Controller Address Strobe ($\overline{ADSC}$). Address advancement through the burst sequence is controlled by the $\overline{ADV}$ input. A two-bit on-chip wraparound burst counter captures the first address in a burst sequence and automatically increments the address for the rest of the burst access.

Byte Write operations are qualified with the Byte Write Enable ($\overline{BWE}$) and Byte Write Select ($\overline{BW}_{[A:D]}$) inputs. A Global Write Enable ($\overline{GW}$) overrides all Byte Write inputs and writes data to all four bytes. All writes are simplified with on-chip synchronous self-timed Write circuitry.

Three synchronous Chip Selects ($\overline{CE}_1$, CE_2, $\overline{CE}_3$) and an asynchronous Output Enable ($\overline{OE}$) provide for easy bank

selection and output tri-state control. $\overline{ADSP}$ is ignored if $\overline{CE}_1$ is HIGH.

Single Read Accesses

This access is initiated when the following conditions are satisfied at clock rise: (1) $\overline{ADSP}$ or $\overline{ADSC}$ is asserted LOW, (2) $\overline{CE}_1$, CE_2, $\overline{CE}_3$ are all asserted active, and (3) the Write signals ($\overline{GW}$, $\overline{BWE}$) are all deserted HIGH. $\overline{ADSP}$ is ignored if $\overline{CE}_1$ is HIGH. The address presented to the address inputs (A) is stored into the address advancement logic and the Address Register while being presented to the memory array. The corresponding data is allowed to propagate to the input of the Output Registers. At the rising edge of the next clock the data is allowed to propagate through the output register and onto the data bus within 2.6 ns (250-MHz device) if $\overline{OE}$ is active LOW. The only exception occurs when the SRAM is emerging from a deselected state to a selected state, its outputs are always tri-stated during the first cycle of the access. After the first cycle of the access, the outputs are controlled by the $\overline{OE}$ signal. Consecutive single Read cycles are supported. Once the SRAM is deselected at clock rise by the chip select and either ADSP or ADSC signals, its output will tri-state immediately.

Single Write Accesses Initiated by $\overline{ADSP}$

This access is initiated when both of the following conditions are satisfied at clock rise: (1) $\overline{ADSP}$ is asserted LOW, and (2) $\overline{CE}_1$, CE_2, $\overline{CE}_3$ are all asserted active. The address presented to A is loaded into the address register and the

address advancement logic while being delivered to the memory array. The Write signals (GW, BWE, and BW$_{[A:D]}$) and ADV inputs are ignored during this first cycle.

ADSP-triggered Write accesses require two clock cycles to complete. If GW is asserted LOW on the second clock rise, the data presented to the DQs inputs is written into the corresponding address location in the memory array. If GW is HIGH, then the Write operation is controlled by BWE and BW$_{[A:D]}$ signals. The CY7C1339G provides Byte Write capability that is described in the Write Cycle Descriptions table. Asserting the Byte Write Enable input (BWE) with the selected Byte Write (BW$_{[A:D]}$) input, will selectively write to only the desired bytes. Bytes not selected during a Byte Write operation will remain unaltered. A synchronous self-timed Write mechanism has been provided to simplify the Write operations.

Because the CY7C1339G is a common I/O device, the Output Enable (OE) must be deserted HIGH before presenting data to the DQs inputs. Doing so will tri-state the output drivers. As a safety precaution, DQs are automatically tri-stated whenever a Write cycle is detected, regardless of the state of OE.

Single Write Accesses Initiated by ADSC

ADSC Write accesses are initiated when the following conditions are satisfied: (1) ADSC is asserted LOW, (2) ADSP is deserted HIGH, (3) CE$_1$, CE$_2$, CE$_3$ are all asserted active, and (4) the appropriate combination of the Write inputs (GW, BWE, and BW$_{[A:D]}$) are asserted active to conduct a Write to the desired byte(s). ADSC-triggered Write accesses require a single clock cycle to complete. The address presented to A is loaded into the address register and the address advancement logic while being delivered to the memory array. The ADV input is ignored during this cycle. If a global Write is conducted, the data presented to the DQs is written into the corresponding address location in the memory core. If a Byte Write is conducted, only the selected bytes are written. Bytes not selected during a Byte Write operation will remain unaltered. A synchronous self-timed Write mechanism has been provided to simplify the Write operations.

Because the CY7C1339G is a common I/O device, the Output Enable (OE) must be deserted HIGH before presenting data to the DQs inputs. Doing so will tri-state the output drivers. As a safety precaution, DQs are automatically tri-stated whenever a Write cycle is detected, regardless of the state of OE.

Burst Sequences

The CY7C1339G provides a two-bit wraparound counter, fed by A1, A0, that implements either an interleaved or linear burst sequence. The interleaved burst sequence is designed specifically to support Intel Pentium applications. The linear burst sequence is designed to support processors that follow a linear burst sequence. The burst sequence is user selectable through the MODE input.

Asserting ADV LOW at clock rise will automatically increment the burst counter to the next address in the burst sequence. Both Read and Write burst operations are supported.

Sleep Mode

The ZZ input pin is an asynchronous input. Asserting ZZ places the SRAM in a power conservation "sleep" mode. Two clock cycles are required to enter into or exit from this "sleep" mode. While in this mode, data integrity is guaranteed. Accesses pending when entering the "sleep" mode are not considered valid nor is the completion of the operation guaranteed. The device must be deselected prior to entering the "sleep" mode. CE$_1$, CE$_2$, CE$_3$, ADSP, and ADSC must remain inactive for the duration of t$_{ZZREC}$ after the ZZ input returns LOW.

Interleaved Burst Address Table (MODE = Floating or V$_{DD}$)

First Address A1, A0	Second Address A1, A0	Third Address A1, A0	Fourth Address A1, A0
00	01	10	11
01	00	11	10

WRITE Cycle, Suspend Burst	Current	H	X	X	L	X	H	H	L	X	L-H	D

Notes:
2. X = "Don't Care." H = Logic HIGH, L = Logic LOW.
3. $\overline{WRITE}$ = L when any one or more Byte Write enable signals ($\overline{BW}_A$, $\overline{BW}_B$, $\overline{BW}_C$, $\overline{BW}_D$) and $\overline{BWE}$ = L or $\overline{GW}$= L. $\overline{WRITE}$ = H when all Byte write enable signals (BW_A, BW_B, BW_C, BW_D), BWE, GW = H.
4. The DQ pins are controlled by the current cycle and the $\overline{OE}$ signal. $\overline{OE}$ is asynchronous and is not sampled with the clock.
5. CE_1, CE_2, and $\overline{CE}_3$ are available only in the TQFP package. BGA package has only 2 chip selects $\overline{CE}_1$ and CE_2.
6. The SRAM always initiates a read cycle when ADSP is asserted, regardless of the state of GW, BWE, or $BW_{[A: D]}$. Writes may occur only on subsequent clocks after the $\overline{ADSP}$ or with the assertion of $\overline{ADSC}$. As a result, $\overline{OE}$ must be driven HIGH prior to the start of the write cycle to allow the outputs to tri-state. $\overline{OE}$ is a don't care for the remainder of the write cycle
7. $\overline{OE}$ is asynchronous and is not sampled with the clock rise. It is masked internally during write cycles. During a read cycle all data bits are tri-state when $\overline{OE}$ is inactive or when the device is deselected, and all data bits behave as output when $\overline{OE}$ is active (LOW).

Partial Truth Table for Read/Write [2, 8]

AC Test Loads and Waveforms

3.3V I/O Test Load

(a)   (b)   (c)

2.5V I/O Test Load

(a)   (b)   (c)
Note:
11. Tested initially and after any design or process change that may affect these parameters

Switching Characteristics Over the Operating Range[12, 13, 14, 15, 16, 17]

| Parameter	Description	250 MHz Min.	250 MHz Max	200 MHz Min.	200 MHz Max	166 MHz Min.	166 MHz Max	133 MHz Min.	133 MHz Max	Unit
t_{POWER}	V_{DD}(Typical) to the first Access[12]	1		1		1		1		ms
Clock										
t_{CYC}	Clock Cycle Time	4.0		5.0		6.0		7.5		ns
t_{CH}	Clock HIGH	1.7		2.0		2.5		3.0		ns
t_{CL}	Clock LOW	1.7		2.0		2.5		3.0		ns
Output Times										
t_{CO}	Data Output Valid After CLK Rise		2.6		2.8		3.5		4.0	ns
t_{DOH}	Data Output Hold After CLK Rise	1.0		1.0		1.5		1.5		ns
t_{CLZ}	Clock to Low-Z[13, 14, 15]	0		0		0		0		ns
t_{CHZ}	Clock to High-Z[13, 14, 15]		2.6		2.8		3.5		4.0	ns
t_{OEV}	$\overline{OE}$ LOW to Output Valid		2.6		2.8		3.5		4.0	ns
t_{OELZ}	$\overline{OE}$ LOW to Output Low-Z[13, 14, 15]	0		0		0		0		ns
t_{OEHZ}	$\overline{OE}$ HIGH to Output High-Z[13, 14, 15]		2.6		2.8		3.5		4.0	ns
Set-up Times										
t_{AS}	Address Set-up Before CLK Rise	1.2		1.2		1.5		1.5		ns
t_{ADS}	$\overline{ADSC}$, $\overline{ADSP}$ Set-up Before CLK Rise	1.2		1.2		1.5		1.5		ns
t_{ADVS}	$\overline{ADV}$ Set-up Before CLK Rise	1.2		1.2		1.5		1.5		ns
t_{WES}	$\overline{GW}$, $\overline{BWE}$, $\overline{BW_X}$ Set-up Before CLK Rise	1.2		1.2		1.5		1.5		ns
t_{DS}	Data Input Set-up Before CLK Rise	1.2		1.2		1.5		1.5		ns
t_{CES}	Chip Enable Set-Up Before CLK Rise	1.2		1.2		1.5		1.5		ns
Hold Times										
t_{AH}	Address Hold After CLK Rise	0.3		0.5		0.5		0.5		ns
t_{ADH}	$\overline{ADSP}$, $\overline{ADSC}$ Hold After CLK Rise	0.3		0.5		0.5		0.5		ns
t_{ADVH}	$\overline{ADV}$ Hold After CLK Rise	0.3		0.5		0.5		0.5		ns
t_{WEH}	$\overline{GW}$, $\overline{BWE}$, $\overline{BW_X}$ Hold After CLK Rise	0.3		0.5		0.5		0.5		ns
t_{DH}	Data Input Hold After CLK Rise	0.3		0.5		0.5		0.5		ns
t_{CEH}	Chip Enable Hold After CLK Rise	0.3		0.5		0.5		0.5		ns

Shaded areas contain advance information.

Notes:
12. This part has a voltage regulator internally; t_{POWER} is the time that the power needs to be supplied above V_{DD}(minimum) initially before a read or write operation can be initiated.
13. t_{CHZ}, t_{CLZ}, t_{OELZ}, and t_{OEHZ} are specified with AC test conditions shown in part (b) of AC Test Loads. Transition is measured ± 200 mV from steady-state voltage.
14. At any given voltage and temperature, t_{OEHZ} is less than t_{OELZ} and t_{CHZ} is less than t_{CLZ} to eliminate bus contention between SRAMs when sharing the same data bus. These specifications do not imply a bus contention condition, but reflect parameters guaranteed over worst case user conditions. Device is designed to achieve High-Z prior to Low-Z under the same system conditions
15. This parameter is sampled and not 100% tested.
16. Timing reference level is 1.5V when V_{DDQ} = 3.3V and is 1.25V when V_{DDQ} = 2.5V.
17. Test conditions shown in (a) of AC Test Loads unless otherwise noted.

## Switching Waveforms

Read Cycle Timing[18]

Burst continued with new base address

Deselect cycle

ADV suspends burst.

Burst wraps around to its initial state

Single READ

BURST READ

DON'T CARE

UNDEFINED
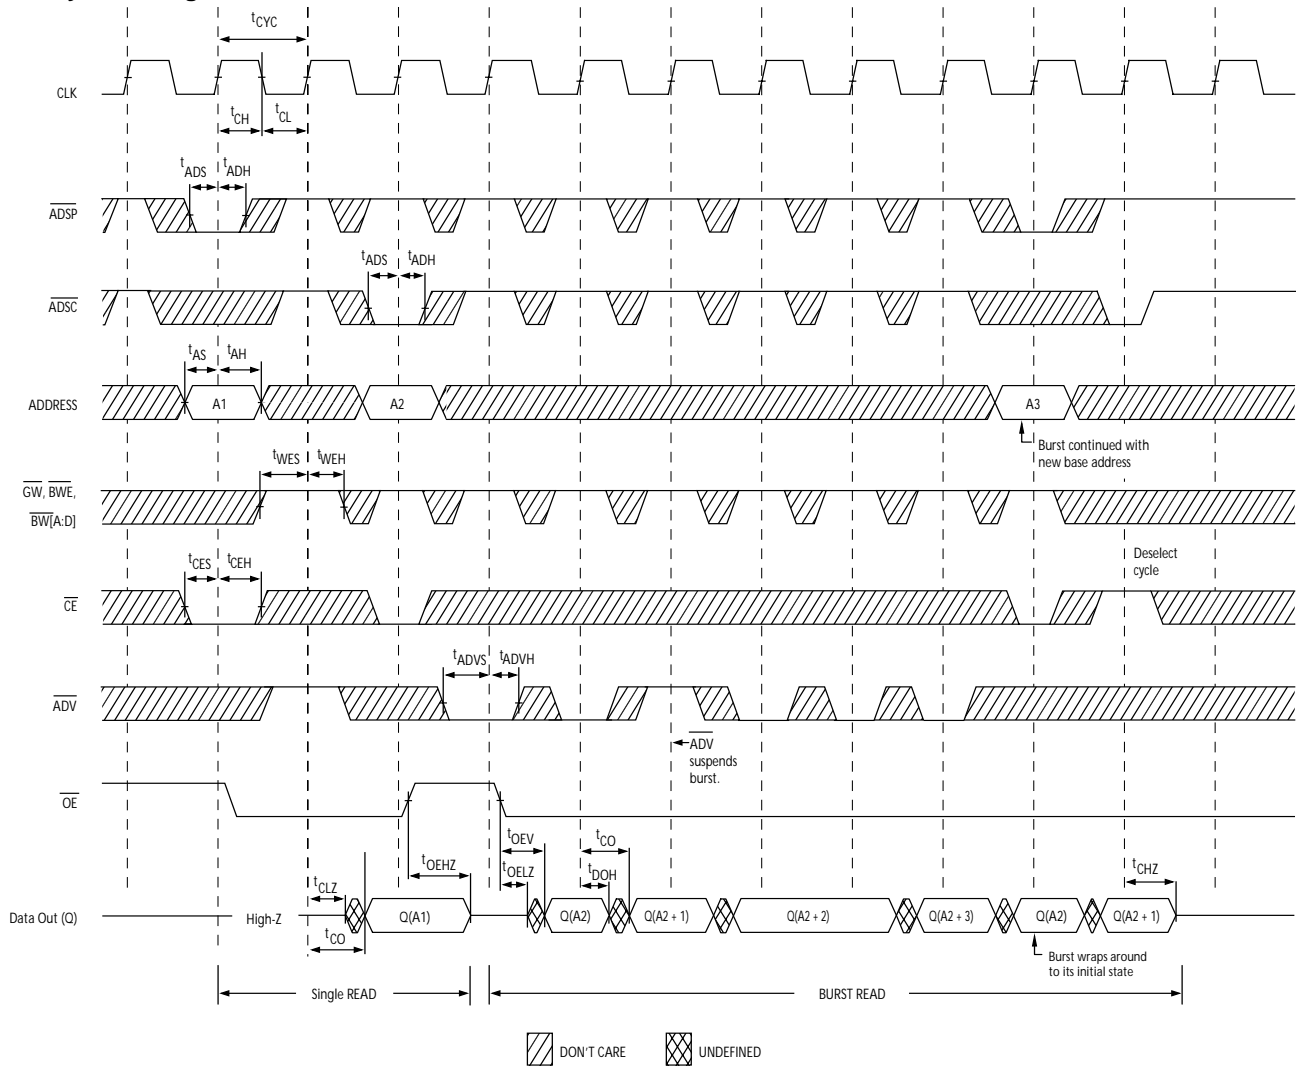

Notes:
18. On this diagram, when $\overline{CE}$ is LOW, $\overline{CE_1}$ is LOW, CE_2 is HIGH and $\overline{CE_3}$ is LOW. When $\overline{CE}$ is HIGH, $\overline{CE_1}$ is HIGH or CE_2 is LOW or $\overline{CE_3}$ is HIGH.
19. Full width write can be initiated by either $\overline{GW}$ LOW; or by $\overline{GW}$ HIGH, $\overline{BWE}$ LOW and $\overline{BW}_{[A:D]}$ LOW.

Switching Waveforms (continued)

Write Cycle Timing[18, 19]
Switching Waveforms (continued)

Read/Write Cycle Timing[18, 20, 21]
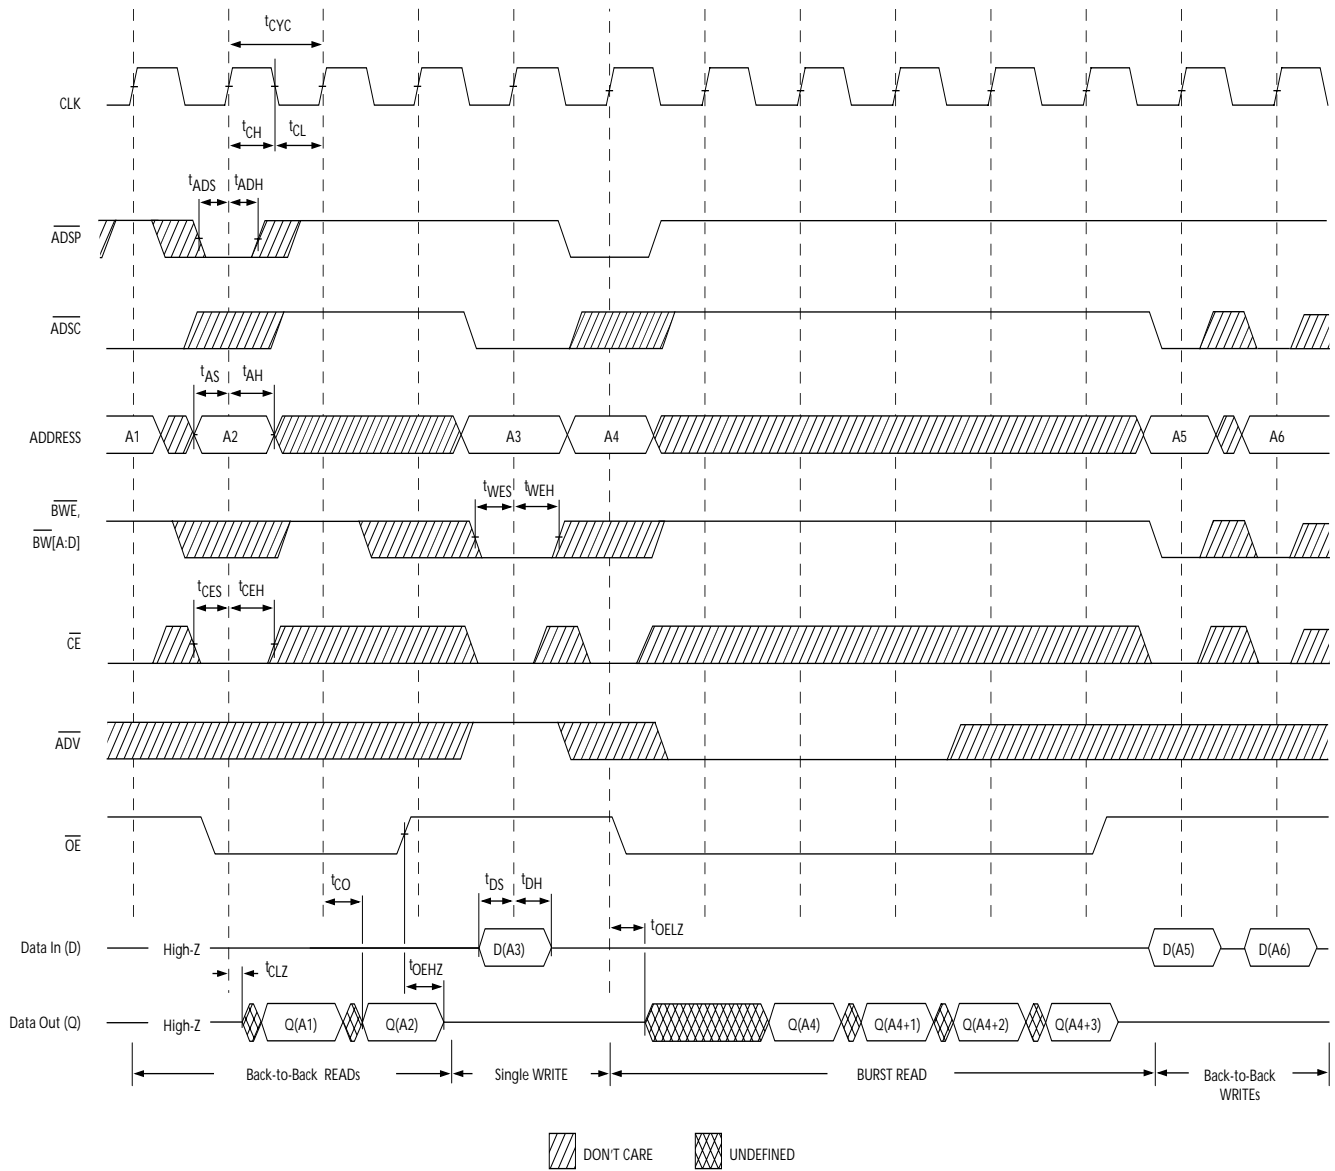

Note:
20. The data bus (Q) remains in high-Z following a WRITE cycle, unless a new read access is initiated by $\overline{ADSP}$ or $\overline{ADSC}$.
21. GW is HIGH.

Switching Waveforms (continued)

ZZ Mode Timing [22, 23]
