

CS5101

Secondary Side Post Regulator for AC/DC and DC/DC Multiple Output Converters

The CS5101 is a bipolar monolithic secondary side post regulator (SSPR) which provides tight regulation of multiple output voltages in AC-DC or DC-DC converters. Leading edge pulse width modulation is used with the CS5101.

The CS5101 is designed to operate over an 8.0 V to 45 V supply voltage (V_{CC}) range and up to a 75 V drive voltage (V_C).

The CS5101 features include a totem pole output with 1.5 A peak output current capability, externally programmable overcurrent protection, an on chip 2.0% precision 5.0 V reference, internally compensated error amplifier, externally synchronized switching frequency, and a power switch drain voltage monitor. It is available in a 14 lead plastic DIP or a 16 lead wide body SO package.

Features

- 1.5 A Peak Output (Grounded Totem Pole)
- 8.0 V to 75 V Gate Drive Voltage
- 8.0 V to 45 V Supply Voltage
- 300 ns Propagation Delay
- 1.0% Error Amplifier Reference Voltage
- Lossless Turn On and Turn Off
- Sleep Mode: < 100 μ A
- Overcurrent Protection with Dedicated Differential Amp
- Synchronization to External Clock
- External Power Switch Drain Voltage Monitor

–	4	DGND	Digital ground.

CIRCUIT DESCRIPTION

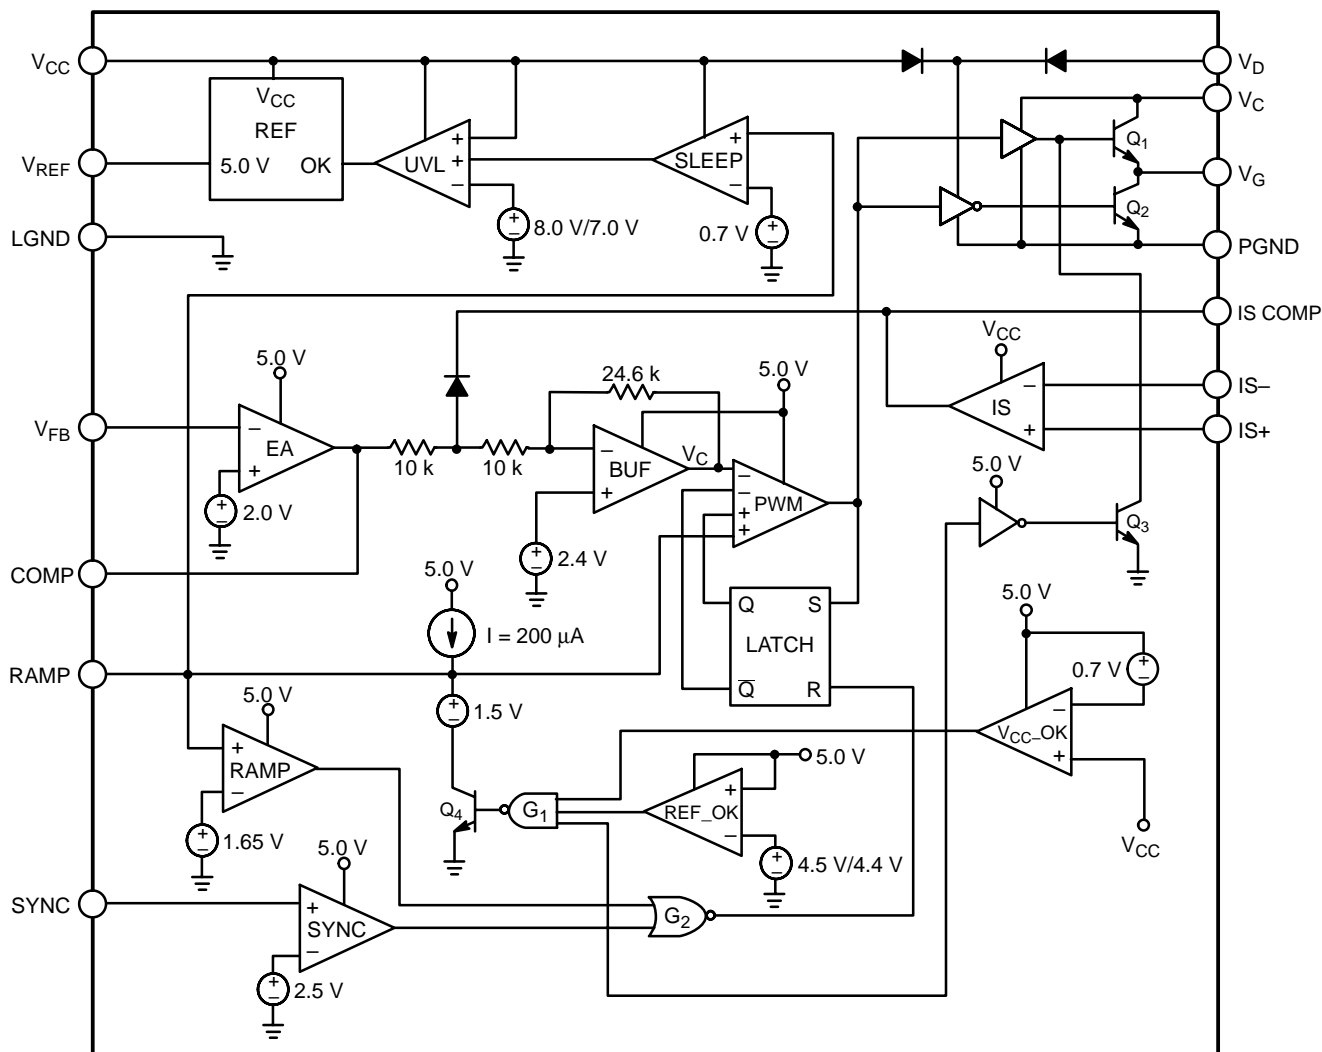

Figure 2. Block Diagram

Theory of Operation

The CS5101 is designed to regulate voltages in multiple output power supplies. Functionally, it is similar to a magnetic amplifier, operating as a switch with a delayed turn-on. It can be used with both single ended and dual ended topologies.

The V_{FB} voltage is monitored by the error amplifier EA. It is compared to an internal reference voltage and the amplified differential signal is fed through an inverting amplifier into the buffer, BUF. The buffered signal is compared at the PWM comparator with the ramp voltage generated by capacitor C_R . When the ramp voltage V_R exceeds the control voltage V_C , the output of the PWM comparator goes high, latching its state through the LATCH, the output stage transistor Q_1 turns on, and the external power switch, usually an N-FET, turns on.

SYNC Function

The SYNC circuit is activated at time t_1 (Figure 3) when the voltage at the SYNC pin exceeds the threshold level (2.5V) of the SYNC comparator. The external ramp capacitor C_R is allowed to charge through the internal current source I (200 μ A). At time t_2 , the ramp voltage intersects with the control voltage V_C and the output of the PWM comparator goes high, turning on the output stage and the external power switch. At the same time, the PWM comparator is latched by the RS latch, LATCH.

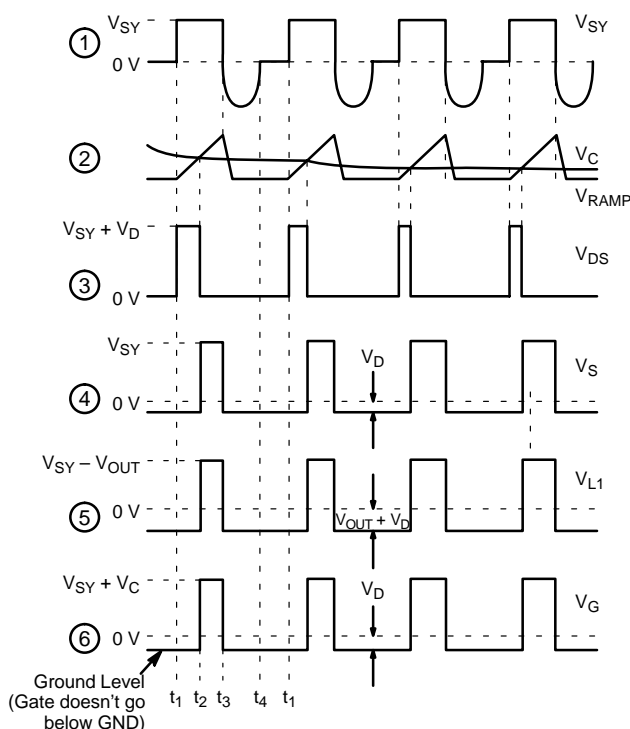

Figure 3. Waveforms for CS5101. The Number to the Left of Each Curve Refers to a Node On the Application Diagram on Page 2.

The logic state of the LATCH can be changed only when both the voltage level of the trailing edge of the power pulse at the SYNC pin is less than the threshold voltage of the SYNC comparator (2.5 V) and the RAMP voltage is less than the threshold voltage of the RAMP comparator (1.65 V). On the negative going transition of the secondary side pulse V_{SY} , gate G_2 output goes high, resetting the latch at time t_3 . Capacitor C_R is discharged through transistor Q_4 . C_R 's output goes low disabling the output stage, and the external power switch (an N-FET) is turned off.

RAMP Function

The value of the ramp capacitor C_R is based on the switching frequency of the regulator and the maximum duty cycle of the secondary pulse V_{SY} .

If the RAMP pin is pulled externally to 0.3 V or below, the SSPR is disabled. Current drawn by the IC is reduced to less than 100 μ A, and the IC is in SLEEP mode.

FAULT Function

The voltage at the V_{CC} pin is monitored by the undervoltage lockout comparator with hysteresis. When V_{CC} falls below the UVL threshold, the 5.0 V reference and all the circuitry running off of it is disabled. Under this condition the supply current is reduced to less than 500 μ A.

The V_{CC} supply voltage is further monitored by the V_{CC_OK} comparator. When V_{CC} is reduced below $V_{REF} - 0.7$ V, a fault signal is sent to gate G_1 . This fault signal, which determines if V_{CC} is absent, works in conjunction with the ramp signal to disable the output, but only after the current cycle has finished and the RS latch is reset. Therefore this fault will not cause the output to turn off during the middle of an on pulse, but rather will utilize lossless turn-off. This feature protects the FET from overvoltage stress. This is accomplished through gate G_1 by driving transistor Q_4 on.

An additional fault signal is derived from the REF_OK comparator. V_{REF} is monitored so to disable the output through gate G_1 when the V_{REF} voltage falls below the OK threshold. As in the V_{CC_OK} fault, the REF_OK fault disables the output after the current cycle has been completed. The fault logic will operate normally only when V_{REF} voltage is within the specification limits of REF_OK.

DRAIN Function

The drain pin, V_D monitors the voltage on the drain of the power switch and derives energy from it to keep the output stage in an off state when V_C or V_{CC} is below the minimum specified voltage.
