SiS 746 AMD Athlon™/AMD Duron™ Clock Synthesizer

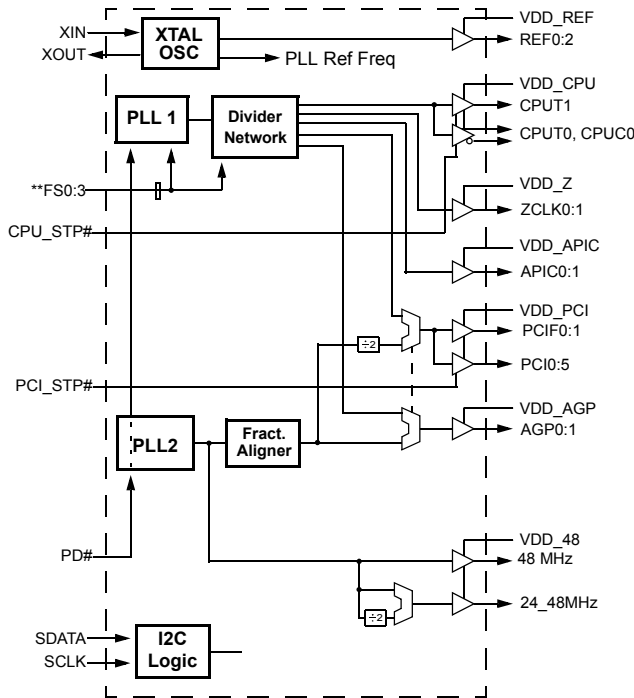

CY28372

Features

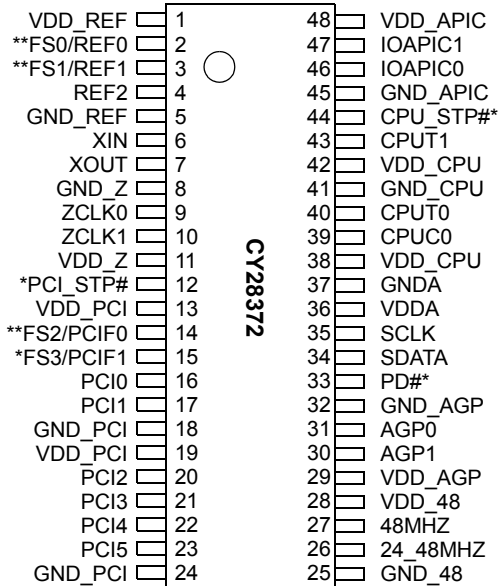

- Supports AMD Athlon™/Duron™ CPU
- 3.3V and 2.5V power supply
- Eight copies of PCI clocks
- One 48-MHz USB clock
- Two copies of ZCLK clocks
- One 48-MHz/24-MHz programmable SIO clock
- One differential CPU clock (opendrain)
- One singled-ended CPU clock (opendrain)
- SMBus support with readback capabilities
- Spread Spectrum electromagnetic interference (EMI) reduction
- 48-pin SSOP package

Pin Description

Pin #.	Name	Type	Description
6	XIN	I	Crystal Connection or External Reference Frequency Input. This pin has dual functions. It can be used as an external 14.318-MHz crystal connection or as an external reference frequency input.
7	XOUT	O	Crystal Connection. Connection for an external 14.318-MHz crystal. If using an external reference, this pin must be left unconnected.
4	REF2	O	Reference Clock. 14.31818 reference outputs.
2, 3	REF[0:1]/ FS[0:1]	O	Reference Clock. 14.31818 reference outputs.
		I	Frequency Select. Sampled upon power-on to determine device operating frequency.
14, 15	PCIF[0:1]/ FS[2:3]	O	Free-running PCI. Independent of PCI_STP#.
		I	Frequency Select. Sampled upon power-on to determine device operating frequency.
16, 17, 20, 21, 22, 23	PCI [0:5]	O	PCI Clock.
12	PCI_STP#	I	PCI Stop. Stops all PCI clocks
40 39	CPUT0 CPUC0	O	Differential CPU Outputs.
43	CPUT1	O	“True” Clock of Differential CPU Outputs. For chipset host bus
44	CPU_STP#	I	CPU Stop. Stops all CPU clocks
9, 10	ZCLK[0:1]	O	MuTIOL Clock Outputs.
46, 47	IOAPIC[0:1]	O	IOAPIC. 2.5 V clock outputs
27	48MHz	O	48-MHz Clock. USB clock outputs
26	24_48MHz	O	24-MHz or 48-MHz Clock. Selectable SIO clock outputs. Default output frequency is 24 MHz, but can be configured for 48 MHz through I ² C.
31, 30	AGP[0:1]	O	AGP Clock.
34	SDATA	I/O	I²C Data. 5v tolerant
35	SCLK	I	I²C Clock. 5v tolerant
33	PD#	I	Power-down Control. Turns off all clock outputs and shuts down device
36	VDDA	PWR	3.3V Analog Power/Ground. Power supply for core logic, PLL circuitry
37	GNDA	PWR	
1, 5, 8, 11, 13, 18, 19, 24, 25, 28, 29, 32	VDD_REF, GND_REF, GND_Z, VDD_Z, VDD_PCI, GND_PCI, GND_48, VDD_48, VDD_AGP, GND_AGP	PWR	3.3V Power and Ground. Power supply for respective output buffers.
38, 41, 42 48, 45	VDD_CPU, GND_CPU, VDD_APIC, GND_APIC	PWR	2.5V Power and Ground. Power supply for respective output buffers.

Serial Data Interface

To enhance the flexibility and function of the clock synthesizer, a two-signal serial interface is provided. Through the Serial Data Interface, various device functions, such as individual clock output buffers, can be individually enabled or disabled. The registers associated with the Serial Data Interface initialize to their default setting upon power-up, and therefore use of this interface is optional. Clock device register changes are normally made upon system initialization, if any are required. The interface can also be used during system operation for power management functions.

Data Protocol

The clock driver serial protocol accepts byte write, byte read, block write, and block read operations from the controller. For block write/read operation, the bytes must be accessed in sequential order from lowest to highest byte (most significant bit first) with the ability to stop after any complete byte has been transferred. For byte write and byte read operations, the system controller can access individually indexed bytes. The offset of the indexed byte is encoded in the command code, as described in *Table 2*.

The block write and block read protocol is outlined in *Table 3* while *Table 4* outlines the corresponding byte write and byte read protocol. The slave receiver address is 11010010 (D2h).

Dial-A-Frequency Feature

SMBus Dial-a-Frequency feature is available in this device via Byte13 and Byte14. P is a large value PLL constant that depends on the frequency selection achieved through the hardware selectors (FS). P value may be determined from the following table.

PD# (Power-down) Clarification

The PD# (Power-down) pin is used to shut off ALL clocks prior to shutting off power to the device. PD# is an asynchronous active LOW input. This signal is synchronized internally to the device powering down the clock synthesizer. PD# is an asynchronous function for powering up the system. When PD# is low, all clocks are driven to a LOW value and held there and the VCO and PLLs are also powered down. All clocks are shut down in a synchronous manner so has not to cause glitches while transitioning to the low 'stopped' state.

PD# – Assertion

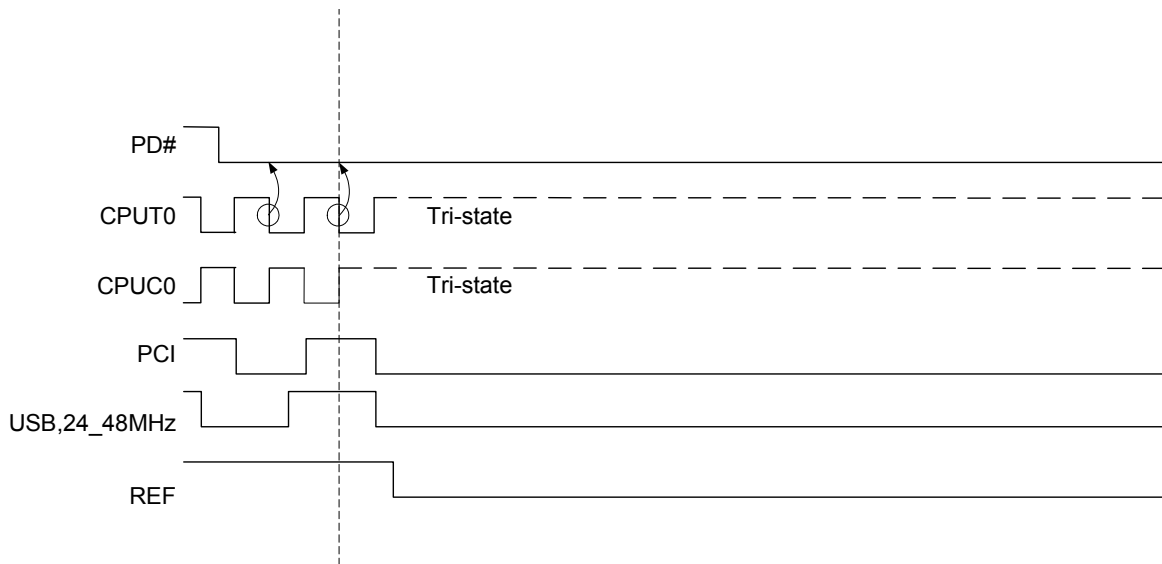

Figure 1. Power-down Assertion Timing Waveforms

PD# – Deassertion

After the clock chip internal PLL is powered up and locked, all outputs will be enabled within a few clock cycles of each other, with the first to last active clock taking no more than two full PCI clock cycles.

Figure 2. Power Down Deassertion Timing Waveforms

Table 6. PD# Functionality

PD#	CPUT	CPUC	AGP	PCIF/PCI	48MHz
1	Normal	Normal	Normal	Normal	Normal
0	Float	Float	Low	Low	Low

CPU_STP# Clarification

The CPU_STP# signal is an active LOW input used for synchronous stopping and starting the CPU output clocks while the rest of the clock generator continues to function.

CPU_STP# – Assertion

When CPU_STP# pin is asserted, all CPUT/C outputs that are set with the SMBus configuration to be stoppable via assertion of CPU_STP# will be stopped after being sampled by two rising CPUC clock edges. The final state of the stopped CPU signals is CPUT = CPUC = three-state.

Figure 3. CPU_STP# Assertion Waveform

CPU_STP# Deassertion

The deassertion of the CPU_STP# signal will cause all CPUT/C outputs that were stopped to resume normal operation in a synchronous manner. Synchronous manner meaning that no short or stretched clock pulses will be produced when the clock resumes. The maximum latency from the deassertion to active outputs is no more than two CPUC clock cycles.

Figure 4. CPU_STP# Deassertion Waveform
PCI_STP# Assertion

The PCI_STP# signal is an active LOW input used for synchronous stopping and starting the PCI outputs while the rest of the clock generator continues to function. The set-up time for capturing PCI_STP# going LOW is 10 ns (t_{setup}). The PCIF clocks will not be affected by this pin if their control bits in the SMBus register are set to allow them to be free running.

Figure 5. PCI_STP# Assertion Waveform
PCI_STP# - Deassertion

The deassertion of the PCI_STP# signal will cause all PCI and stoppable PCIF clocks to resume running in a synchronous manner within two PCI clock periods after PCI_STP# transitions to a high level.
