

# FSCQ-Series

FSCQ0565RT / FSCQ0765RT / FSCQ0965RT / FSCQ1265RT  
FSCQ1465RT / FSCQ1565RT / FSCQ1565RP  
Green Mode Fairchild Power Switch (FPS™)

## Features

- Optimized for Quasi-Resonant Converter (QRC)
- Advanced Burst-Mode Operation for under 1W Standby Power Consumption
- Pulse-by-Pulse Current Limit
- Over Load Protection (OLP) - Auto Restart
- Over Voltage Protection (OVP) - Auto Restart
- Abnormal Over Current Protection (AOCP) - Latch
- Internal Thermal Shutdown (TSD) - Latch
- Under Voltage Lock Out (UVLO) with Hysteresis
- Low Startup Current (typical : 25uA)
- Internal High Voltage SenseFET
- Built-in Soft Start (20ms)
- Extended Quasi-Resonant Switching

## Applications

- CTV
- Audio Amplifier

## Related Application Notes

## Description

In general, a Quasi-Resonant Converter (QRC) shows lower EMI and higher power conversion efficiency compared to conventional hard-switched converter with a fixed switching frequency. Therefore, a QRC is well suited for noise-sensitive applications, such as color TV and audio. Each product in the FSCQ-Series contains an integrated Pulse Width Modulation (PWM) controller and a SenseFET, and is specifically designed for quasi-resonant off-line Switch Mode Power Supplies (SMPS) with minimal external components. The PWM controller includes an integrated fixed frequency oscillator, under voltage lockout, leading edge blanking (LEB), optimized gate driver, internal soft start, temperature-compensated precise current sources for a loop compensation, and self protection circuitry. Compared with a discrete MOSFET and PWM controller solution, the FSCQ-Series can reduce total cost, component count, size, and weight, while simultaneously increasing efficiency, productivity, and system reliability. These devices provide a basic platform that is well suited for cost-effective designs of quasi-resonant switching flyback converters.

OUTPUT POWER TABLE <sup>(3)</sup>		
PRODUCT	230VAC ±15% <sup>(2)</sup>	85-265VAC
	Open Frame <sup>(1)</sup>	Open Frame <sup>(1)</sup>
FSCQ0565RT	70W	60 W

### Pin Definitions

Pin Number	Pin Name	Pin Function Description
1	Drain	High voltage power SenseFET drain connection.
2	GND	This pin is the control ground and the SenseFET source.
3	Vcc	This pin is the positive supply input. This pin provides internal operating current for both start-up and steady-state operation.
4	Vfb	This pin is internally connected to the inverting input of the PWM comparator. The collector of an opto-coupler is typically tied to this pin. For stable operation, a capacitor should be placed between this pin and GND. If the voltage of this pin reaches 7.5V, the over load protection triggers, which results in the FPS shutting down.
5	Sync	This pin is internally connected to the sync detect comparator for quasi-resonant switching. In normal quasi-resonant operation, the threshold of the sync comparator is 4.6V/2.6V. Whereas, the sync threshold is changed to 3.0V/1.8V in an extended quasi-resonant operation.

# Electrical Characteristics

## Electrical Characteristics

## Functional Description

1. **Startup:** Figure 4 shows the typical startup circuit and the transformer auxiliary winding for the FSCQ-Series. Before the FSCQ-Series begins switching, it consumes only startup current (typically 25uA). The current supplied from the AC line charges the external capacitor (C<sub>a1</sub>) that is connected to the V<sub>cc</sub> pin. When V<sub>cc</sub> reaches the start voltage of 15V (V<sub>START</sub>), the FSCQ-Series begins switching, and its current consumption increases to I<sub>OP</sub>. Then, the FSCQ-Series continues its normal switching operation and the power required for the FSCQ-Series is supplied from the transformer auxiliary winding, unless V<sub>cc</sub> drops below the stop voltage of 9V (V<sub>STOP</sub>). To guarantee the stable operation of the control IC, V<sub>cc</sub> has under voltage lockout (UVLO) with 6V hysteresis. Figure 5 shows the relationship between the operating supply current of the FSCQ-Series and the supply voltage (V<sub>cc</sub>).

Figure 4. Startup circuit

Figure 5. Relationship Between Operating Supply Current and V<sub>cc</sub> Voltage

The minimum average of the current supplied from the AC is given by

$$I_{sup}^{avg} = \left( \frac{\sqrt{2} \cdot V_{ac}^{min}}{\pi} - \frac{V_{start}}{2} \right) \cdot \frac{1}{R_{str}}$$

where  $V_{ac}^{min}$  is the minimum input voltage,  $V_{start}$  is the FSCQ-Series start voltage (15V), and  $R_{str}$  is the startup resistor. The startup resistor should be chosen so that  $I_{sup}^{avg}$  is larger than the maximum startup current (50uA).

Once the resistor value is determined, the maximum loss in the startup resistor is obtained as

$$Loss = \frac{1}{R_{str}} \cdot \left( \frac{(V_{ac}^{max})^2}{2} + V_{start}^2 - \frac{2\sqrt{2} \cdot V_{start} \cdot V_{ac}^{max}}{\pi} \right)$$

where  $V_{ac}^{max}$  is the maximum input voltage. The startup resistor should have properly-rated dissipation wattage.

2. **Synchronization:** The FSCQ-Series employs a quasi-resonant switching technique to minimize the switching noise and loss. In this technique, a capacitor (Cr) is added between the MOSFET drain and the source as shown in Figure 6. The basic waveforms of the quasi-resonant converter are shown in Figure 7. The external capacitor lowers the rising slope of the drain voltage to reduce the EMI caused when the MOSFET turns off. To minimize the MOSFET's switching loss, the MOSFET should be turned on when the drain voltage reaches its minimum value as shown in Figure 7.

Figure 6. Synchronization Circuit

Figure 7. Quasi-resonant Operation Waveforms

The minimum drain voltage is indirectly detected by monitoring the Vcc winding voltage as shown in Figure 6 and 8. Choose voltage dividers,  $R_{SY1}$  and  $R_{SY2}$ , so that the peak voltage of the sync signal ( $V_{sypk}$ ) is lower than the OVP voltage (12V) to avoid triggering OVP in normal operation. It is typical to set  $V_{sypk}$  to be lower than OVP voltage by 3-4 V. To detect the optimum time to turn on MOSFET, the sync capacitor ( $C_{SY}$ ) should be determined so that  $T_R$  is the same with  $T_Q$  as shown in Figure 8. The  $T_R$  and  $T_Q$  are given as, respectively

$$T_R = R_{SY2} \cdot C_{SY} \cdot \ln\left(\frac{V_{co}}{2.6} \cdot \frac{R_{SY2}}{R_{SY1} + R_{SY2}}\right)$$

$$T_Q = \pi \cdot \sqrt{L_m \cdot C_{eo}}$$

$$V_{co} = \frac{N_a \cdot (V_o + V_{FO})}{N_s} - V_{Fa}$$

where  $L_m$  is the primary side inductance of the transformer, and  $N_s$  and  $N_a$  are the number of turns for the output winding and Vcc winding, respectively,  $V_{FO}$  and  $V_{Fa}$  are the diode forward voltage drops of the output winding and Vcc winding, respectively, and  $C_{eo}$  is the sum of the output capacitance of the MOSFET and the external capacitor, Cr.

Figure 8. Normal Quasi-Resonant Operation Waveforms

Figure 9. Extended Quasi-Resonant Operation

In general, the QRC has a limitation in a wide load range application, since the switching frequency increases as the output load decreases, resulting in a severe switching loss in the light load condition. To overcome this limitation, the FSCQ-Series employs an extended quasi-resonant switching operation. Figure 9 shows the mode change between normal and extended quasi-resonant operations. In the normal quasi-resonant operation, the FSCQ-Series enters into the extended quasi-resonant operation when the switching frequency exceeds 90kHz as the load reduces. To reduce the switching frequency, the MOSFET is turned on when the drain voltage reaches the second minimum level, as shown in Figure 10.

Once the FSCQ-Series enters into the extended quasi-resonant operation, the first sync signal is ignored. After the first sync signal is applied, the sync threshold levels are changed from 4.6V and 2.6V to 3V and 1.8V, respectively, and the MOSFET turn-on time is synchronized to the second sync signal. The FSCQ-Series returns to its normal quasi-resonant operation when the switching frequency reaches 45kHz as the load increases.

Figure 10. Extended Quasi-Resonant Operation Waveforms

**3. Feedback Control:** The FSCQ-Series employs current mode control, as shown in Figure 11. An opto-coupler (such as Fairchild's H11A817A) and shunt regulator (such as Fairchild's KA431) are typically used to implement the feedback network. Comparing the feedback voltage with the voltage across the  $R_{sense}$  resistor plus an offset voltage makes it possible to control the switching duty cycle. When the reference pin voltage of the KA431 exceeds the internal reference voltage of 2.5V, the H11A817A LED current increases, pulling down the feedback voltage and reducing the duty cycle. This event typically happens when the input voltage is increased or the output load is decreased.

**3.1 Pulse-by-Pulse Current Limit:** Because current mode control is employed, the peak current through the SenseFET is limited by the inverting input of the PWM comparator ( $V_{fb}^*$ ) as shown in Figure 11. The feedback current ( $I_{FB}$ ) and internal resistors are designed so that the maximum cathode voltage of diode D2 is about 2.8V, which occurs when all  $I_{FB}$  flows through the internal resistors. Since D1 is blocked when the feedback voltage ( $V_{fb}$ ) exceeds 2.8V, the maximum voltage of the cathode of D2 is clamped at this voltage, thus clamping  $V_{fb}^*$ . Therefore, the peak value of the current through the SenseFET is limited.

**3.2 Leading Edge Blanking (LEB) :** At the instant the internal Sense FET is turned on, there is usually a high current spike through the Sense FET, caused by the external resonant capacitor across the MOSFET and secondary-side rectifier reverse recovery. Excessive voltage across the  $R_{sense}$  resistor can lead to incorrect feedback operation in the current mode PWM control. To counter this effect, the FSCQ-Series employs a leading edge blanking (LEB) circuit. This circuit inhibits the PWM comparator for a short time ( $T_{LEB}$ ) after the Sense FET is turned on.

Figure 11. Pulse Width Modulation (PWM) Circuit

**4. Protection Circuits:** The FSCQ-Series has several self-protective functions such as over load protection (OLP), abnormal over current protection (AOCP), over voltage protection (OVP), and thermal shutdown (TSD). OLP and OVP are auto-restart mode protections, while TSD and AOCP are latch mode protections. Because these protection circuits are fully integrated into the IC without external components, the reliability can be improved without increasing cost.

**-Auto-restart mode protection:** Once the fault condition is detected, switching is terminated and the SenseFET remains off. This causes  $V_{cc}$  to fall. When  $V_{cc}$  falls to the under voltage lockout (UVLO) stop voltage of 9V, the protection is reset and the FSCQ-Series consumes only startup current (25uA). Then, the  $V_{cc}$  capacitor is charged up, since the current supplied through the startup resistor is larger than the current that the FPS consumes. When  $V_{cc}$  reaches the start voltage of 15V, the FSCQ-Series resumes its normal operation. If the fault condition is not removed, the SenseFET remains off and  $V_{cc}$  drops to stop voltage again. In this manner, the auto-restart can alternately enable and disable the switching of the power SenseFET until the fault condition is eliminated (see Figure 12).

**-Latch mode protection:** Once this protection is triggered, switching is terminated and the Sense FET remains off until the AC power line is un-plugged. Then,  $V_{cc}$  continues charging and discharging between 9V and 15V. The latch is reset only when  $V_{cc}$  is discharged to 6V by un-plugging the

AC power line.

Figure 12. Auto Restart Mode Protection

**4.1 Over Load Protection (OLP):** Overload is defined as the load current exceeding its normal level due to an unexpected abnormal event. In this situation, the protection circuit should trigger to protect the SMPS. However, even when the SMPS is in the normal operation, the over load protection circuit can be triggered during the load transition. To avoid this undesired operation, the over load protection circuit is designed to trigger after a specified time to determine whether it is a transient situation or an overload situation. Because of the pulse-by-pulse current limit capability, the maximum peak current through the SenseFET is limited, and therefore the maximum input power is restricted with a given input voltage. If the output consumes more than this maximum power, the output voltage ( $V_o$ ) decreases below the set voltage. This reduces the current through the opto-coupler LED, which also reduces the opto-coupler transistor current, thus increasing the feedback voltage ( $V_{fb}$ ). If  $V_{fb}$  exceeds 2.8V, D1 is blocked, and the 5uA current source starts to charge  $C_B$  slowly up to  $V_{cc}$ . In this condition,  $V_{fb}$  continues increasing until it reaches 7.5V, then the switching operation is terminated as shown in Figure 13. The delay time for shutdown is the time required to charge  $C_B$  from 2.8V to 7.5V with 5uA. In general, a 20 ~ 50 ms delay time is typical for most applications. OLP is implemented in auto restart mode.

Figure 13. Over Load Protection

**4.2 Abnormal Over Current Protection (AOC):** When the secondary rectifier diodes or the transformer pins are shorted, a steep current with extremely high di/dt can flow through the SenseFET during the LEB time. Even though the FSCQ-Series has OLP (Over Load Protection), it is not enough to protect the FSCQ-Series in that abnormal case, since severe current stress will be imposed on the SenseFET until the OLP triggers. The FSCQ-Series has an internal AOC (Abnormal Over Current Protection) circuit as shown in Figure 14. When the gate turn-on signal is applied to the power SenseFET, the AOC block is enabled and monitors the current through the sensing resistor. The voltage across the resistor is then compared with a preset AOC level. If the sensing resistor voltage is greater than the AOC level, the set signal is applied to the latch, resulting in the shutdown of SMPS. This protection is implemented in the latch mode.

Figure 14. AOC Block

**4.3 Over Voltage Protection (OVP) :** If the secondary side feedback circuit malfunctions or a solder defect causes an open in the feedback path, the current through the opto-coupler transistor becomes almost zero. Then,  $V_{fb}$  climbs up in a similar manner to the over load situation, forcing the

preset maximum current to be supplied to the SMPS until the over load protection triggers. Because more energy than required is provided to the output, the output voltage may exceed the rated voltage before the over load protection triggers, resulting in the breakdown of the devices in the secondary side. In order to prevent this situation, an over voltage protection (OVP) circuit is employed. In general, the peak voltage of the sync signal is proportional to the output voltage and the FSCQ-Series uses a sync signal instead of directly monitoring the output voltage. If the sync signal exceeds 12V, an OVP is triggered resulting in a shutdown of SMPS. In order to avoid undesired triggering of OVP during normal operation, the peak voltage of the sync signal should be designed to be below 12V. This protection is implemented in the auto restart mode.

**4.4 Thermal Shutdown (TSD) :** The SenseFET and the control IC are built in one package. This makes it easy for the control IC to detect abnormal over temperature of the SenseFET. When the temperature exceeds approximately 150°C, the thermal shutdown triggers. This protection is implemented in the latch mode.

**5. Soft Start :** The FSCQ-Series has an internal soft-start circuit that increases PWM comparator's inverting input voltage together with the SenseFET current slowly after it starts up. The typical soft start time is 20msec. The pulse width to the power switching device is progressively increased to establish the correct working conditions for transformers, inductors, and capacitors. Increasing the pulse width to the power switching device also helps prevent transformer saturation and reduces the stress on the secondary diode during startup. For a fast build up of the output voltage, an offset is introduced in the soft-start reference current.

**6. Burst Operation :** In order to minimize the power consumption in the standby mode, the FSCQ-Series employs burst operation. Once FSCQ-Series enters into the burst mode, FSCQ-Series allows all output voltages and effective switching frequency to be reduced. Figure 15 shows the typical feedback circuit for C-TV applications. In normal operation, the picture on signal is applied and the transistor Q1 is turned on, which de-couples R3, Dz and D1 from the feedback network. Therefore, only  $V_{O1}$  is regulated by the feedback circuit in normal operation and determined by R1 and R2 as

$$V_{O1}^{norm} = 2.5 \cdot \left( \frac{R_1 + R_2}{R_2} \right)$$

In the standby mode, the picture ON signal is disabled and the transistor Q1 is turned off, which couples R3, Dz, and D1 to the reference pin of KA431. Then,  $V_{O2}$  is determined by the zener diode breakdown voltage. Assuming that the forward voltage drop of D1 is 0.7V,  $V_{O2}$  in standby mode is approximately given by

$$V_{O2}^{stby} = V_Z + 0.7 + 2.5$$

**Figure 15. Typical Feedback Circuit to Drop Output Voltage in Standby Mode**

Figure 17 shows the burst mode operation waveforms. When the picture ON signal is disabled, Q1 is turned off and R3 and Dz are connected to the reference pin of KA431 through D1. Before  $V_{O2}$  drops to  $V_{O2}^{stby}$ , the voltage on the reference pin of KA431 is higher than 2.5V, which increases the current through the opto LED. This pulls down the feedback voltage ( $V_{FB}$ ) of FSCQ-Series and forces FSCQ-Series to stop switching. If the switching is disabled longer than 1.4ms, FSCQ-Series enters into burst operation and the operating current is reduced from  $I_{OP}$  to 0.25mA ( $I_{OB}$ ). Since there is no switching,  $V_{O2}$  decreases until it reaches  $V_{O2}^{stby}$ . As  $V_{O2}$  reaches  $V_{O2}^{stby}$ , the current through the opto LED decreases allowing the feedback voltage to rise. When the feedback voltage reaches 0.4V, FSCQ-Series resumes switching with a predetermined peak drain current of 0.9A. After burst switching for 1.4ms, FSCQ-Series stops switching and checks the feedback voltage. If the feedback voltage is below 0.4V, FSCQ-Series stops switching until the feedback voltage increases to 0.4V. If the feedback voltage is above 0.4V, FSCQ-Series goes back to the normal operation.

The output voltage drop circuit can be implemented alternatively as shown in Figure 16. In the circuit of Figure 16, the FSCQ-Series goes into burst mode, when picture off signal is applied to Q1. Then,  $V_{O2}$  is determined by the zener diode breakdown voltage. Assuming that the forward

voltage drop of opto LED is 1V, the approximate value of  $V_{O2}$  in standby mode is given by

$$V_{O2}^{stby} = V_Z + 1$$

# FSCQ0765RT Typical Application Circuit

Application	Output Power	Input Voltage	Output Voltage (Max Current)
C-TV	83W	Universal input (90-270Vac)	12V (1A)
			18V (0.5A)
			125V (0.4A)
			24V (0.5A)

## Features

- High Efficiency (>83% at 90Vac Input)
- Wider Load Range through the Extended Quasi-Resonant Operation
- Low Standby Mode Power Consumption (<1W)
- Low Component Count
- Enhanced System Reliability Through Various Protection Functions
- Internal Soft-Start (20ms)

## Key Design Notes

- 24V output is designed to drop to around 8V in standby mode

C209	470pF / 1kV	Ceramic Capacitor			

# FSCQ1565RT Typical Application Circuit

Application	Output Power	Input Voltage	Output Voltage (Max Current)
C-TV	160W	Universal input (90-270Vac)	8.5V (0.5A)
			15V (0.5A)
			140V (0.8A)
			24V (1.5A)

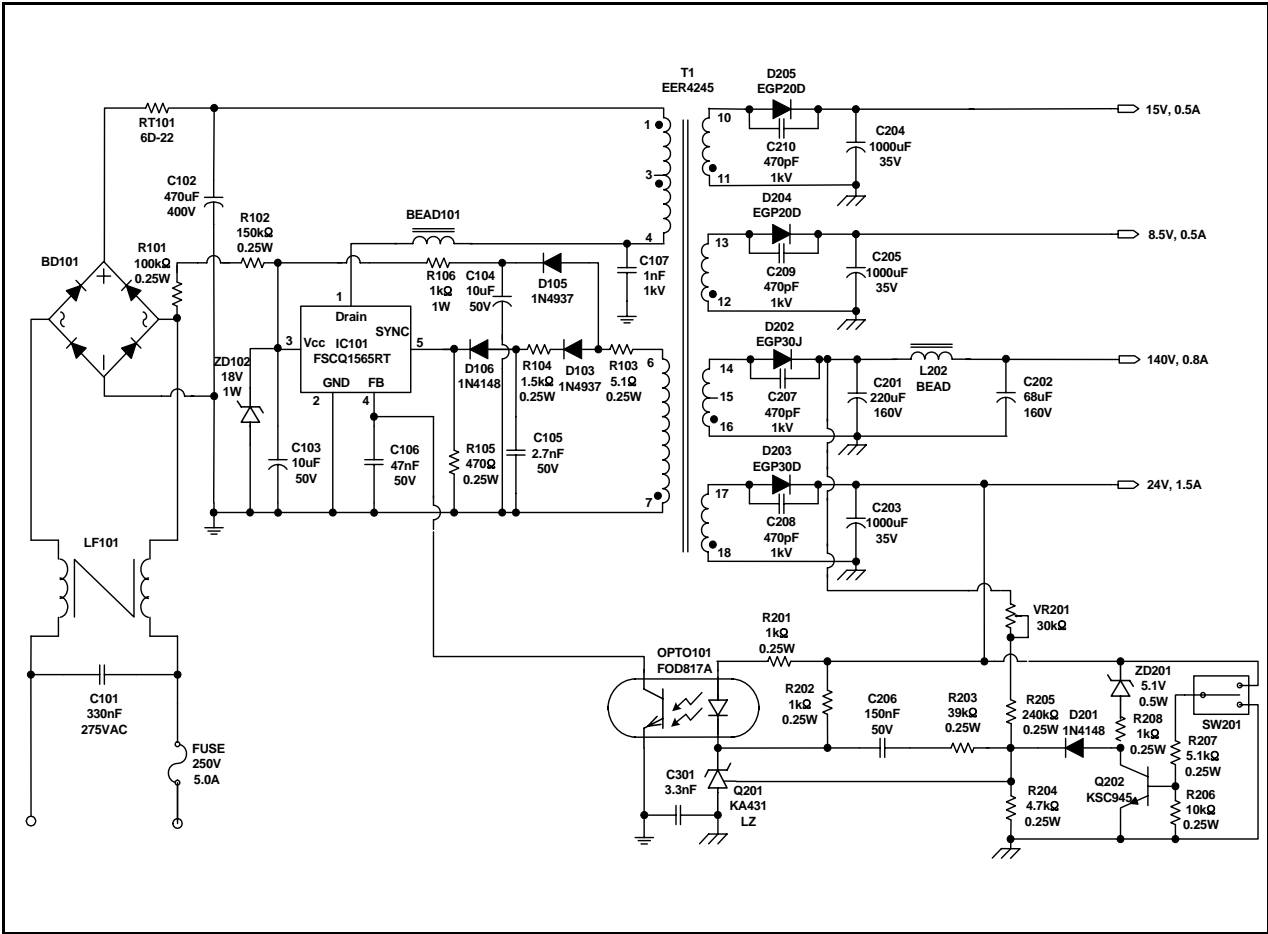

## Features

- High Efficiency (>83% at 90Vac Input)
- Wider Load Range through the Extended Quasi-Resonant Operation
- Low Standby Mode Power Consumption (<1W)
- Low Component Count
- Enhanced System Reliability Through Various Protection Functions
- Internal Soft-Start (20ms)

## Key Design Notes

- 24V output is designed to drop to around 8V in standby mode

## 1. Schematic

## 2. Transformer Schematic Diagram

## 3. Winding Specification

No	Pin (s→f)	Wire	Turns	Winding Method
N <sub>24</sub>	18 - 17	0.65 <sup>φ</sup> × 2	5	Space Winding
N <sub>p1</sub>	1 - 3	0.08 <sup>φ</sup> × 20 × 2	13	Center Winding
N <sub>140V/2</sub>	16 - 15	0.08 <sup>φ</sup> × 20 × 2	15	Center Winding
N <sub>p2</sub>	3 - 4	0.08 <sup>φ</sup> × 20 × 2	13	Center Winding
N <sub>140V/2</sub>	15 - 14	0.08 <sup>φ</sup> × 20 × 2	14	Center Winding
N <sub>8.5V</sub>	12 - 13	0.6 <sup>φ</sup> × 1	2	Space Winding
N <sub>15V</sub>	11 - 10	0.6 <sup>φ</sup> × 1	3	Space Winding
N <sub>a</sub>	7 - 6	0.3 <sup>φ</sup> × 1	8	Space Winding

## 4. Electrical Characteristics

	Pin	Specification	Remarks
Inductance	1 - 4	220uH ± 5%	1kHz, 1V
Leakage Inductance	1 - 4	10uH Max	2 <sup>nd</sup> all short

## 5. Core & Bobbin

Core : EER4245

Bobbin : EER4245(18Pin)

### DISCLAIMER

FAIRCHILD SEMICONDUCTOR RESERVES THE RIGHT TO MAKE CHANGES WITHOUT FURTHER NOTICE TO ANY PRODUCTS HEREIN TO IMPROVE RELIABILITY, FUNCTION OR DESIGN. FAIRCHILD DOES NOT ASSUME ANY LIABILITY ARISING OUT OF THE APPLICATION OR USE OF ANY PRODUCT OR CIRCUIT DESCRIBED HEREIN; NEITHER DOES IT CONVEY ANY LICENSE UNDER ITS PATENT RIGHTS, NOR THE RIGHTS OF OTHERS.

### LIFE SUPPORT POLICY

FAIRCHILD'S PRODUCTS ARE NOT AUTHORIZED FOR USE AS CRITICAL COMPONENTS IN LIFE SUPPORT DEVICES OR SYSTEMS WITHOUT THE EXPRESS WRITTEN APPROVAL OF THE PRESIDENT OF FAIRCHILD SEMICONDUCTOR CORPORATION. As used herein:

1. Life support devices or systems are devices or systems which, (a) are intended for surgical implant into the body, or (b) support or sustain life, and (c) whose failure to perform when properly used in accordance with instructions for use provided in the labeling, can be reasonably expected to result in a significant injury of the user.
2. A critical component in any component of a life support device or system whose failure to perform can be reasonably expected to cause the failure of the life support device or system, or to affect its safety or effectiveness.
