200MHz Unity-Gain Stable Operational Amplifier

The EL2073 is a precision voltage-feedback amplifier featuring a 200MHz gain-bandwidth product, fast settling time, excellent differential gain and differential phase performance, and a minimum of 50mA output current drive over temperature.

The EL2073 is unity-gain stable with a -3dB bandwidth of 400MHz. It has a very low 200µV of input offset voltage, only 2µA of input bias current, and a fully symmetrical differential input. Like all voltage-feedback operational amplifiers, the EL2073 allows the use of reactive or non-linear components in the feedback loop. This combination of speed and versatility makes the EL2073 the ideal choice for all op-amp applications requiring high speed and precision, including active filters, integrators, sample-and-holds, and log amps. The low distortion, high output current, and fast settling makes the EL2073 an ideal amplifier for signal-processing and digitizing systems.

Pinout

**EL2073
(8-PIN PDIP, SO)
TOP VIEW**

Features

- 200MHz gain-bandwidth product
- Unity-gain stable
- Ultra low video distortion = 0.01%/0.015° @ NTSC/PAL
- Conventional voltage-feedback topology
- Low offset voltage = 200µV
- Low bias current = 2µA
- Low offset current = 0.1µA
- Output current = 50mA over temperature
- Fast settling = 13ns to 0.1%
- Low distortion = -60dB HD2, -70dB HD3 @ 20MHz, 2V_{PP} A_V = +1

Applications

- High resolution video
- Active filters/integrators
- High-speed signal processing
- ADC/DAC buffers
- Pulse/RF amplifiers
- Pin diode receivers
- Log amplifiers
- Photo multiplier amplifiers
- High speed sample-and-holds

Ordering Information

dP	Differential Phase	NTSC	25°C		0.015	0.05	°pp
dG	Differential Gain	30MHz	25°C		0.1		%pp
dP	Differential Phase	30MHz	25°C		0.1		°pp
VBW	± 0.1 dB Bandwidth Flatness		25°C	25	50		MHz

NOTES:

1. Large-signal bandwidth calculated using $LSBW = \text{Slew Rate} / 2\pi V_{PEAK}$.
2. All distortion measurements are made with $V_{OUT} = 2V_{PP}$, $R_L = 100\Omega$.
3. Video performance measured at $A_V = +1$ with 2 times normal video level across $R_L = 100\Omega$. This corresponds to standard video levels across a back-terminated 50Ω load, i.e., 0–100 IRE, 40IREpp giving a $1V_{PP}$ video signal across the 50Ω load. For other values of R_L , see curves.

Applications Information

Product Description

The EL2073 is a wideband monolithic operational amplifier built on a high-speed complementary bipolar process. The EL2073 uses a classical voltage-feedback topology which allows it to be used in a variety of applications where current-feedback amplifiers are not appropriate because of restrictions placed upon the feedback element used with the amplifier. The conventional topology of the EL2073 allows, for example, a capacitor to be placed in the feedback path, making it an excellent choice for applications such as active

filters, sample-and-holds, or integrators. Similarly, because of the ability to use diodes in the feedback network, the EL2073 is an excellent choice for applications such as log amplifiers.

The EL2073 also has excellent DC specifications: 200μV, V_{OS} , 2μA I_B , 0.1μA I_{OS} , and 90dB of CMRR. These specifications allow the EL2073 to be used in DC-sensitive applications such as difference amplifiers. Furthermore, the current noise of the EL2073 is only 3.2pA/√Hz, making it an excellent choice for high-sensitivity transimpedance amplifier configurations.

Gain-Bandwidth Product

The EL2073 has a gain-bandwidth product of 200MHz. For gains greater than 4, its closed-loop -3dB bandwidth is approximately equal to the gain-bandwidth product divided by the noise gain of the circuit. For gains less than 4, higher-order poles in the amplifier's transfer function contribute to even higher closed loop bandwidths. For example, the EL2073 has a -3dB bandwidth of 400MHz at a gain of +1, dropping to 200MHz at a gain of +2. It is important to note that the EL2073 has been designed so that this "extra" bandwidth in low-gain applications does not come at the expense of stability. As seen in the typical performance curves, the EL2073 in a gain of +1 only exhibits 1dB of peaking with a 100Ω load.

Video Performance

An industry-standard method of measuring the video distortion of a component such as the EL2073 is to measure the amount of differential gain (dG) and differential phase (dP) that it introduces. To make these measurements, a 0.286V_{PP} (40 IRE) signal is applied to the device with 0V DC offset (0 IRE) at either 3.58MHz for NTSC, 4.43MHz for PAL, or 30MHz for HDTV. A second measurement is then made at 0.714V DC offset (100 IRE). Differential gain is a measure of the change in amplitude of the sine wave, and is measured in percent. Differential phase is a measure of the change in phase, and is measured in degrees.

For signal transmission and distribution, a back-terminated cable (75Ω in series at the drive end, and 75Ω to ground at the receiving end) is preferred since the impedance match at both ends will absorb any reflections. However, when double termination is used, the received signal is halved; therefore a gain of 2 configuration is typically used to compensate for the attenuation.

The EL2073 has been designed to be among the best video amplifiers in the marketplace today. It has been thoroughly characterized for video performance in the topology described above, and the results have been included as minimum dG and dP specifications and as typical performance curves. In a gain of +2, driving 150Ω, with standard video test levels at the input, the EL2073 exhibits dG and dP of only 0.01% and 0.015° at NTSC and PAL. Because dG and dP vary with different DC offsets, the superior video performance of the EL2073 has been characterized over the entire DC offset range from -0.714V to +0.714V. For more information, refer to the curves of dG and dP vs DC Input Offset.

The excellent output drive capability of the EL2073 allows it to drive up to 4 back-terminated loads with excellent video performance. With 4 150Ω loads, dG and dP are only 0.15% and 0.08° at NTSC and PAL. For more information, refer to the curves for Video Performance vs Number of 150Ω Loads.

Output Drive Capability

The EL2073 has been optimized to drive 50Ω and 75Ω loads. It can easily drive 6V_{PP} into a 50Ω load. This high output drive capability makes the EL2073 an ideal choice for RF, IF and video applications. Furthermore, the current drive of the EL2073 remains a minimum of 50mA at low temperatures. The EL2073 is current-limited at the output, allowing it to withstand momentary shorts to ground. However, power dissipation with the output shorted can be in excess of the power-dissipation capabilities of the package.

Capacitive Loads

Although the EL2073 has been optimized to drive resistive loads as low as 50Ω, capacitive loads will decrease the amplifier's phase margin which may result in peaking, overshoot, and possible oscillation. For optimum AC

performance, capacitive loads should be reduced as much as possible or isolated via a series output resistor. Coax lines can be driven, as long as they are terminated with their characteristic impedance. When properly terminated, the capacitance of coaxial cable will not add to the capacitive load seen by the amplifier. Capacitive loads greater than 10pF should be buffered with a series resistor (Rs) to isolate the load capacitance from the amplifier output. A curve of recommended Rs vs Cload has been included for reference. Values of Rs were chosen to maximize resulting bandwidth without peaking.

Printed-Circuit Layout

As with any high-frequency device, good PCB layout is necessary for optimum performance. Ground-plane construction is highly recommended, as is good power supply bypassing. A 1μF–10μF tantalum capacitor is recommended in parallel with a 0.01μF ceramic capacitor. All pin lengths should be as short as possible, and all bypass capacitors should be as close to the device pins as possible. Parasitic capacitances should be kept to an absolute minimum at both inputs and at the output. Resistor values should be kept under 1000Ω to 2000Ω because of the RC time constants associated with the parasitic capacitance. Metal-film and carbon resistors are both acceptable, use of wire-wound resistors is not recommended because of parasitic inductance. Similarly, capacitors should be low-inductance for best performance. If possible, solder the EL2073 directly to the PC board without a socket. Even high quality sockets add parasitic capacitance and inductance which can potentially degrade performance. Because of the degradation of AC performance due to parasitics, the use of surface-mount components (resistors, capacitors, etc.) is also recommended.
