## Single and Dual Ultra-Low Noise, Ultra-Low Distortion, Rail-to-Rail, Low Power Op Amp

The ISL55191 and ISL55291 are single and dual high speed operational amplifiers featuring low noise, low distortion, and rail-to-rail output drive capability. They are designed to operate with single and dual supplies from +5 VDC ( $\pm 2.5 \mathrm{VDC}$ ) down to +3 VDC ( $\pm 1.5 \mathrm{VDC}$ ). These amplifiers draw 6.1 mA of quiescent supply current per amplifier. For power conservation, this family offers a low-power shutdown mode that reduces supply current to $21 \mu \mathrm{~A}$ and places the amplifiers' output into a high impedance state. The ISL55191 ENABLE logic places the device in the shutdown mode with $\mathrm{EN}=0$ and the ISL55291 is placed in the shutdown mode with $\overline{\mathrm{EN}}=1$.

These amplifiers have excellent input and output overload recovery times and outputs that swing rail-to-rail. Their input common mode voltage range includes ground. The ISL55191 and ISL55291 are stable at gains as low as 10 with an input referred noise voltage of $1.3 \mathrm{nV} / \mathrm{VHz}$ and harmonic distortion products -94dBc (2nd) and -104dBc (3rd) below a $1 \mathrm{MHz} 2 \mathrm{~V}_{\mathrm{P}-\mathrm{P}}$ signal.
The ISL55191 is available in space-saving 8 Ld DFN and 8 Ld SOIC packages. The ISL55291 is available in a 10 Ld MSOP package.

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and $100 \%$ matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb -free soldering operations. Intersil Pb -free products are MSL classified at Pb -free peak reflow temperatures that meet or exceed the Pb -free requirements of IPC/JEDEC J STD-020.

## Features

- $1.3 \mathrm{nV} / \sqrt{ } \mathrm{Hz}$ input voltage noise, $\mathrm{f}_{\mathrm{O}}=1 \mathrm{kHz}$
- Harmonic Distortion $-94 \mathrm{dBc},-104 \mathrm{dBc}, \mathrm{f}_{\mathrm{O}}=1 \mathrm{MHz}$
- Stable at gains as low as 10
- 800 MHz gain bandwidth product $\left(A_{V}=10\right)$
- $260 \mathrm{~V} / \mu \mathrm{s}$ slew rate
- 6.1 mA supply current $(21 \mu \mathrm{~A}$ in disable mode)
- $800 \mu \mathrm{~V}$ maximum offset voltage
- $12 \mu \mathrm{~A}$ input bias current
- 3 V to 5.5 V single supply voltage range
- Rail-to-rail output
- Pb-free plus anneal available (RoHS compliant)

## Applications

- High speed pulse applications
- Low noise signal processing
- ADC buffers
- DAC output amplifiers
- Radio systems
- Portable equipment

## Applications Information

## Product Description

The ISL55191 and ISL55291 are voltage feedback operational amplifiers designed for communication and imaging applications requiring very low voltage and current noise. Both parts features low distortion while drawing moderately low supply current. The ISL55191 and ISL55291 use a classical voltage-feedback topology which allows them to be used in a variety of applications where currentfeedback amplifiers are not appropriate because of restrictions placed upon the feedback element used with the amplifier.

## Enable/Power-Down

Both devices can be operated from a single supply with a voltage range of +3 V to +5 V , or from split $\pm 1.5 \mathrm{~V}$ to $\pm 2.5 \mathrm{~V}$. The logic level input to the ENABLE pins are TTL compatible and are referenced to the -V terminal in both single and split supply applications. The following discussion assumes single supply operation.

The ISL55191 uses a logic "0" (<0.8V) to disable the amplifier and the ISL55291 uses a logic "1" (>2V) to disable its amplifiers. In this condition, the output(s) will be in a high impedance state and the amplifier(s) current will be reduced to $21 \mu \mathrm{~A}$. The ISL55191 has an internal pull-up on the EN pin and is enabled by either floating or tying the EN pin to a voltage >2V. The ISL55291 has internal pull-downs on the $\overline{\mathrm{EN}}$ pins and are enabled by either floating or tying the $\overline{\mathrm{EN}}$ pins to a voltage $<0.8 \mathrm{~V}$. The enable pins should be tied directly to their respective supply pins when not being used ( $\overline{\mathrm{EN}}$ tied to -V for the ISL55291 and EN tied to +V for the ISL55191).

## Current Limiting

The ISL55191 and ISL55291 have no internal currentlimiting circuitry. If the output is shorted, it is possible to exceed the Absolute Maximum Rating for output current or power dissipation, potentially resulting in the destruction of the device.

## Power Dissipation

It is possible to exceed the $+150^{\circ} \mathrm{C}$ maximum junction temperatures under certain load and power-supply conditions. It is therefore important to calculate the maximum junction temperature ( $\mathrm{T}_{\mathrm{JMAX}}$ ) for all applications to determine if power supply voltages, load conditions, or package type need to be modified to remain in the safe operating area. These parameters are related as follows:

$$
\begin{equation*}
\mathrm{T}_{\text {JMAX }}=\mathrm{T}_{\text {MAX }}+\left(\theta_{\mathrm{JA}} \times \mathrm{PD}_{\mathrm{MAXTOTAL}}\right) \tag{EQ.1}
\end{equation*}
$$

where:

- PDMAXTOTAL is the sum of the maximum power dissipation of each amplifier in the package ( $\mathrm{PD}_{\mathrm{MAX}}$ )
- $\mathrm{PD}_{\mathrm{MAX}}$ for each amplifier can be calculated as follows:

(EQ. 2)
where:
- $\mathrm{T}_{\text {MAX }}=$ Maximum ambient temperature
- $\theta_{\mathrm{JA}}=$ Thermal resistance of the package
- $P D_{\text {MAX }}=$ Maximum power dissipation of 1 amplifier
- $\mathrm{V}_{\mathrm{S}}=$ Supply voltage
- $I_{\text {MAX }}=$ Maximum supply current of 1 amplifier
- $V_{\text {OUTMAX }}=$ Maximum output voltage swing of the application
- $\mathrm{R}_{\mathrm{L}}=$ Load resistance

## Power Supply Bypassing and Printed Circuit Board Layout

As with any high frequency device, good printed circuit board layout is necessary for optimum performance. Low impedance ground plane construction is essential. Surface mount components are recommended, but if leaded components are used, lead lengths should be as short as possible. The power supply pins must be well bypassed to reduce the risk of oscillation. The combination of a $4.7 \mu \mathrm{~F}$ tantalum capacitor in parallel with a $0.01 \mu \mathrm{~F}$ capacitor has been shown to work well when placed at each supply pin.

For good AC performance, parasitic capacitance should be kept to a minimum, especially at the inverting input. When ground plane construction is used, it should be removed from the area near the inverting input to minimize any stray capacitance at that node. Carbon or Metal-Film resistors are acceptable with the Metal-Film resistors giving slightly less peaking and bandwidth because of additional series inductance. Use of sockets (particularly for the SOIC package) should be avoided if possible. Sockets add parasitic inductance and capacitance which will result in additional peaking and overshoot.

For inverting gains, this parasitic capacitance has little effect because the inverting input is a virtual ground, but for noninverting gains, this capacitance (in conjunction with the feedback and gain resistors) creates a pole in the feedback path of the amplifier. This pole, if low enough in frequency, has the same destabilizing effect as a zero in the forward open-loop response. The use of large-value feedback and gain resistors exacerbates the problem by further lowering the pole frequency (increasing the possibility of oscillation.).

FIGURE 44. GROUND SIDE CURRENT SENSE AMPLIFIER

## Current Sense Application Circuit

The schematic in Figure 44 provides an example of utilizing the ISL55191 high speed performance with the ground sensing input capability to implement a single-supply, G = 10 differential low side current sense amplifier. The reference voltage applied to $\mathrm{V}_{\text {REF }}(+2.5 \mathrm{~V}$ ) defines the amplifier output OA current sense reference voltage at one half the supply voltage level ( $\mathrm{V}_{\mathrm{S}}=+5 \mathrm{VDC}$ ), and $\mathrm{R}_{\text {SENSE }}$ sets the current sense gain and full scale values. In this example the current gain is 10A/V over a maximum current range of slightly less than $\pm 25 \mathrm{~A}$ with $\mathrm{R}_{\text {SENSE }}=0.01 \Omega$. The amplifier $\mathrm{V}_{\text {IO }}$ error $(800 \mu \mathrm{~V}$ max $)$ and input bias offset current $\mathrm{l}_{\mathrm{I}}$ error $(0.7 \mu \mathrm{~A})$ together contribute less than $10 \mathrm{mV}(100 \mathrm{~mA})$ at the output for better than $0.2 \%$ full scale accuracy.

The amplifier's high slew rate and fast pulse response make this circuit suitable for low-side current sensing in PMWM and motor control applications. The excellent input overload recovery response enables the circuit to maintain performance in the presence of parasitic inductance that cause fast rise and falling edge spikes that can momentarily overload the input stage of the amplifier.

NOTES:

1. Controlling dimensions are in mm . Dimensions in () for reference only
2. Unless otherwise specified, tolerance : Decimal $\pm 0.05$

Angular $\pm 2^{\circ}$
3. Dimensioning and tolerancing conform to JEDEC STD MO220-D.
4. The configuration of the pin \#1 identifier is optional, but must be located within the zone indicated. The pin \#1 identifier may be either a mold or mark feature.
5. Tiebar shown (if present) is a non-functional feature.
