

## 600kHz/1.2MHz PWM Step-Up Regulator

The ISL97516 is a high frequency, high efficiency step-up voltage regulator operated at constant frequency PWM mode. With an internal 2.0A, 200mΩ MOSFET, it can deliver up to 1A output current at over 90% efficiency. The selectable 600kHz and 1.2MHz allows smaller inductors and faster transient response. An external compensation pin gives the user greater flexibility in setting frequency compensation allowing the use of low ESR Ceramic output capacitors.

When shut down, it draws <math><1\mu\text{A}</math> of current and can operate down to 2.3V input supply. These features along with 1.2MHz switching frequency makes it an ideal device for portable equipment and TFT-LCD displays.

The ISL97516 is available in an 8 Ld MSOP package with a maximum height of 1.1mm. The device is specified for operation over the full -40°C to +85°C temperature range.

### Pinout

### Features

- >90% Efficiency
- 2.0A, 200mΩ Power MOSFET
- 2.3V to 5.5V Input
- Up to 25V Output
- 600kHz/1.2MHz Switching Frequency Selection
- Adjustable Soft-Start
- Internal Thermal Protection
- 1.1mm Max Height 8 Ld MSOP Package
- Pb-free Plus Anneal Available (RoHS compliant)

### Applications

- TFT-LCD displays
- DSL modems
- PCMCIA cards
- Digital cameras
- GSM/CDMA phones
- Portable equipment
- Handheld devices

### Ordering Information

PART NUMBER (Note)	PART MARKING	PACKAGE (Pb-Free)	PKG. DWG. #
ISL97516IUZ-T	7516Z	8 Ld MSOP	MDP0043
ISL97516IUZ-TK	7516Z	8 Ld MSOP	MDP0043

NOTE: Intersil Pb-free plus anneal products employ special Pb-free material sets; molding compounds/die attach materials and 100% matte tin plate termination finish, which are RoHS compliant and compatible with both SnPb and Pb-free soldering operations. Intersil Pb-free products are MSL classified at Pb-free peak reflow temperatures that meet or exceed the Pb-free requirements of IPC/JEDEC J STD-020.

Applications Information

The ISL97516 is a high frequency, high efficiency boost regulator operated at constant frequency PWM mode. The boost converter stores energy from an input voltage source and deliver it to a higher output voltage. The input voltage range is 2.3V to 5.5V and output voltage range is 5V to 25V. The switching frequency is selectable between 600kHz and 1.2MHz allowing smaller inductors and faster transient response. An external compensation pin gives the user greater flexibility in setting output transient response and tighter load regulation. The converter soft-start characteristic can also be controlled by external C<sub>SS</sub> capacitor. The EN pin allows the user to completely shutdown the device.

Boost Converter Operations

Figure 11 shows a boost converter with all the key components. In steady state operating and continuous conduction mode where the inductor current is continuous, the boost converter operates in two cycles. During the first cycle, as shown in Figure 12, the internal power FET turns

on and the Schottky diode is reverse biased and cuts off the current flow to the output. The output current is supplied from the output capacitor. The voltage across the inductor is V<sub>IN</sub> and the inductor current ramps up in a rate of V<sub>IN</sub>/L, L is the inductance. The inductance is magnetized and energy is stored in the inductor. The change in inductor current is:

$$\Delta I_{L1} = \Delta T1 \times \frac{V_{IN}}{L}$$

$$\Delta T1 = \frac{D}{F_{SW}}$$

D = Duty Cycle

$$\Delta V_O = \frac{I_{OUT}}{C_{OUT}} \times \Delta T_1 \tag{EQ. 1}$$

During the second cycle, the power FET turns off and the Schottky diode is forward biased, (Figure 13). The energy stored in the inductor is pumped to the output supplying output current and charging the output capacitor. The Schottky diode side of the inductor is clamp to a Schottky diode above the output voltage. So the voltage drop across the inductor is  $V_{IN} - V_{OUT}$ . The change in inductor current during the second cycle is:

$$\Delta I_L = \Delta T_2 \times \frac{V_{IN} - V_{OUT}}{L}$$

$$\Delta T_2 = \frac{1 - D}{F_{SW}} \quad (EQ. 2)$$

For stable operation, the same amount of energy stored in the inductor must be taken out. The change in inductor current during the two cycles must be the same.

$$\Delta I_1 + \Delta I_2 = 0$$

$$\frac{D}{F_{SW}} \times \frac{V_{IN}}{L} + \frac{1 - D}{F_{SW}} \times \frac{V_{IN} - V_{OUT}}{L} = 0$$

$$\frac{V_{OUT}}{V_{IN}} = \frac{1}{1 - D} \quad (EQ. 3)$$

FIGURE 13. BOOST CONVERTER - CYCLE 2, POWER SWITCH OPEN

**Output Voltage**

An external feedback resistor divider is required to divide the output voltage down to the nominal 1.294V reference voltage. The current drawn by the resistor network should be limited to maintain the overall converter efficiency. The maximum value of the resistor network is limited by the feedback input bias current and the potential for noise being coupled into the feedback pin. A resistor network less than 100k is recommended. The boost converter output voltage is determined by the relationship:

$$V_{OUT} = V_{FB} \times \left( 1 + \frac{R_1}{R_2} \right) \quad (EQ. 4)$$

The nominal VFB voltage is 1.294V.

**Inductor Selection**

The inductor selection determines the output ripple voltage, transient response, output current capability, and efficiency. Its selection depends on the input voltage, output voltage, switching frequency, and maximum output current. For most applications, the inductance should be in the range of 2μH to 33μH. The inductor maximum DC current specification must be greater than the peak inductor current required by the regulator. The peak inductor current can be calculated:

$$I_{L(PEAK)} = \frac{I_{OUT} \times V_{OUT}}{V_{IN}} + 1/2 \times \frac{V_{IN} \times (V_{OUT} - V_{IN})}{L \times V_{OUT} \times FREQ} \quad (EQ. 5)$$

**Output Capacitor**

Low ESR capacitors should be used to minimized the output voltage ripple. Multilayer ceramic capacitors (X5R and X7R) are preferred for the output capacitors because of their lower ESR and small packages. Tantalum capacitors with higher ESR can also be used. The output ripple can be calculated as:

$$\Delta V_O = \frac{I_{OUT} \times D}{F_{SW} \times C_O} + I_{OUT} \times ESR \quad (EQ. 6)$$

For noise sensitive application, a 0.1μF placed in parallel with the larger output capacitor is recommended to reduce the switching noise coupled from the LX switching node.

### Schottky Diode

In selecting the Schottky diode, the reverse break down voltage, forward current and forward voltage drop must be considered for optimum converter performance. The diode must be rated to handle 2.0A, the current limit of the ISL97516. The breakdown voltage must exceed the maximum output voltage. Low forward voltage drop, low leakage current, and fast reverse recovery will help the converter to achieve the maximum efficiency.

### Input Capacitor

The value of the input capacitor depends the input and output voltages, the maximum output current, the inductor value and the noise allowed to put back on the input line. For most applications, a minimum 10 $\mu$ F is required. For applications that run close to the maximum output current limit, input capacitor in the range of 22 $\mu$ F to 47 $\mu$ F is recommended.

The ISL97516 is powered from the VIN. A High frequency 0.1 $\mu$ F bypass cap is recommended to be close to the VIN pin to reduce supply line noise and ensure stable operation.

### Loop Compensation

The ISL97516 incorporates a transconductance amplifier in its feedback path to allow the user some adjustment on the transient response and better regulation. The ISL97516 uses current mode control architecture which has a fast current sense loop and a slow voltage feedback loop. The fast current feedback loop does not require any compensation. The slow voltage loop must be compensated for stable operation. The compensation network is a series RC network from COMP pin to ground. The resistor sets the high frequency integrator gain for fast transient response and the capacitor sets the integrator zero to ensure loop stability. For most applications, the compensation resistor in the range of 2k to 7.5k and the compensation capacitor in the range of 3nF to 10nF.

### Soft-Start

The soft-start is provided by an internal 6 $\mu$ A current source charges the external C<sub>SS</sub>, the peak MOSFET current is limited by the voltage on the capacitor. This in turn controls the rising rate of the output voltage. The regulator goes through the start-up sequence as well after the EN pin is pulled to HI.

### Frequency Selection

The ISL97516 switching frequency can be user selected to operate at either constant 620kHz or 1.25MHz. Connecting F<sub>SEL</sub> pin to ground sets the PWM switching frequency to 620kHz. When connecting F<sub>SEL</sub> high or V<sub>DD</sub>, the switching frequency is set to 1.25MHz.

### Shutdown Control

When the EN pin is pulled down, the ISL97516 is shutdown reducing the supply current to <1 $\mu$ A.

### Maximum Output Current

The MOSFET current limit is nominally 2.0A and guaranteed 1.7A. This restricts the maximum output current, I<sub>OMAX</sub>, based on the following formula:

$$I_L = I_{L-AVG} + (1/2 \times \Delta I_L) \quad (\text{EQ. 7})$$

where:

I<sub>L</sub> = MOSFET current limit

I<sub>L-AVG</sub> = average inductor current

$\Delta I_L$  = inductor ripple current

$$\Delta I_L = \frac{V_{IN} \times [(V_O + V_{DIODE}) - V_{IN}]}{L \times (V_O + V_{DIODE}) \times F_S} \quad (\text{EQ. 8})$$

V<sub>DIODE</sub> = Schottky diode forward voltage, typically, 0.6V

F<sub>S</sub> = switching frequency, 600kHz or 1.2MHz

$$I_{L-AVG} = \frac{I_{OUT}}{1-D}$$

D = MOSFET turn-on ratio:

$$D = 1 - \frac{V_{IN}}{V_{OUT} + V_{DIODE}} \quad (\text{EQ. 9})$$

Table 1 gives typical maximum I<sub>OUT</sub> values for 1.2MHz switching frequency and 10 $\mu$ H inductor.

TABLE 1.

V <sub>IN</sub> (V)	V <sub>OUT</sub> (V)	I <sub>OMAX</sub> (mA)
2.5	5	870
2.5	9	500
2.5	12	380
3.3	5	1150
3.3	9	655
3.3	12	500
5	9	990
5	12	750

### Cascaded MOSFET Application

An 25V N-channel MOSFET is integrated in the boost regulator. For the applications where the output voltage is greater than 25V, an external cascaded MOSFET is needed as shown in Figure 12. The voltage rating of the external MOSFET should be greater than A<sub>VDD</sub>.

FIGURE 14. CASCADED MOSFET TOPOLOGY FOR HIGH OUTPUT VOLTAGE APPLICATIONS

### DC PATH BLOCK APPLICATION

Note that there is a DC path in the boost converter from the input to the output through the inductor and diode, hence the input voltage will be seen at output with a forward voltage drop of diode before the part is enabled. If this voltage is not desired, the following circuit can be inserted between input and inductor to disconnect the DC path when the part is disabled.
