

FEATURES

- **8 DACs in the Board Space of an S0-8**
- 2.7V to 5.5V Single Supply Operation
- $I_{CC(TYP)} = 450\mu A$, Just $56\mu A$ per DAC
- **$1\mu A$ Sleep Mode for Extended Battery Life**
- Restores Last DAC Setting After Sleep
- Asynchronous CLR Function
- Power-On Reset Initializes All DACs to Zero
- **Rail-to-Rail Voltage Outputs Drive up to 1000pF**
- Three-Wire Serial Interface with Schmitt Trigger Inputs and Daisy-Chain Capability
- Differential Nonlinearity: $\leq \pm 0.75\text{LSB}$ Max

APPLICATIONS

- Mobile Communications
- Digitally Controlled Amplifiers and Attenuators
- Portable Battery-Powered Instruments
- Automatic Calibration for Manufacturing
- Remote Industrial Devices

DESCRIPTION

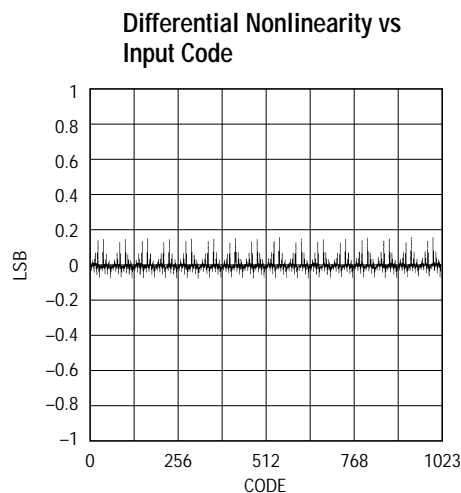

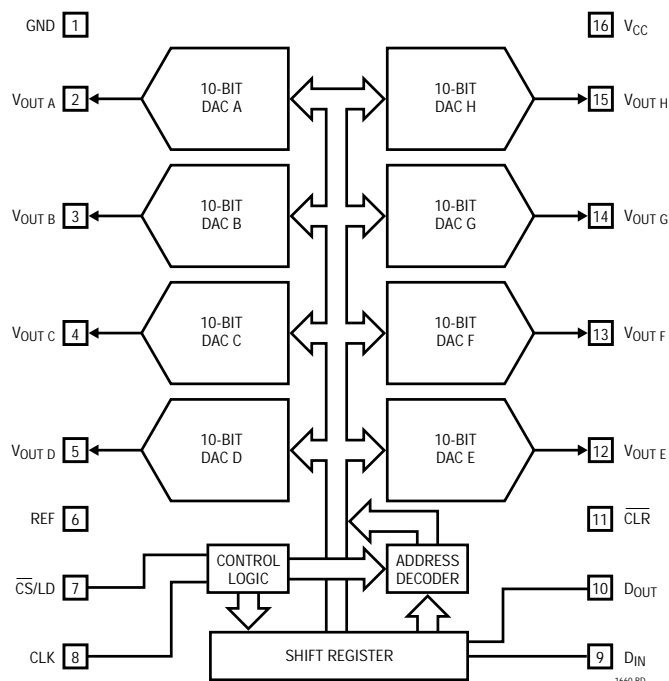

The LTC[®]1660 integrates eight high quality addressable 10-bit digital-to-analog converters (DACs) in a single tiny 16-pin Narrow SSOP package. Each buffered DAC consumes just $56\mu A$ total supply current, yet is capable of supplying DC output currents in excess of 5mA and reliably driving capacitive loads up to 1000pF.

Linear Technology's proprietary, inherently monotonic architecture provides excellent linearity while allowing for an exceptionally small external form factor.

Ultralow supply current, power-saving Sleep Mode and extremely compact size make the LTC1660 ideal for battery-powered applications, while its straightforward usability, high performance and wide supply range make it an excellent choice as a general purpose converter.

 LTC and LT are registered trademarks of Linear Technology Corporation.

The ● denotes specifications which apply over the full operating temperature range.

Note 1: Absolute maximum ratings are those values beyond which the life of a device may be impaired.

Note 2: Nonlinearity and monotonicity are defined from code 20 to code 1023 (full scale). See Applications Information.

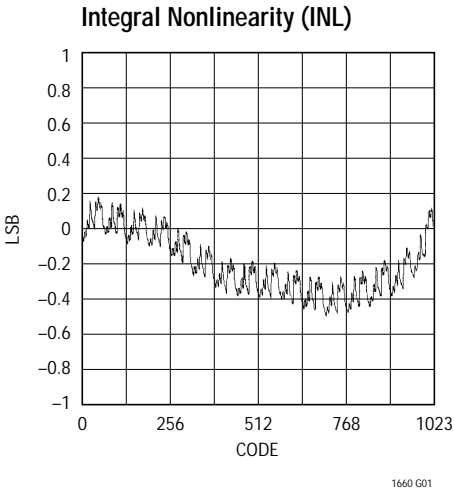

Note 3: Digital inputs at 0V or V_{CC} .

Note 4: Load is $10k\Omega$ in parallel with $100pF$.

Note 5: $V_{CC} = V_{REF} = 5V$. DAC switched between $0.1V_{FS}$ and $0.9V_{FS}$, i.e., codes $k = 102$ and $k = 922$.

Note 6: Guaranteed by design and not subject to test.

TYPICAL PERFORMANCE CHARACTERISTICS

PIN FUNCTIONS

GND (Pin 1): System Ground.

$V_{OUT A}$ to $V_{OUT H}$ (Pins 2-5 and 12-15): DAC Analog Voltage Outputs. The output range is

$$0 \text{ to } V_{REF} \left(1 - \frac{1}{1024}\right)$$

REF (Pin 6): Reference Voltage Input. $0V \leq V_{REF} \leq V_{CC}$.

\overline{CS}/LD (Pin 7): Serial Interface Chip Select/Load Input. When \overline{CS}/LD is low, CLK is enabled for shifting data on D_{IN} into the register. When \overline{CS}/LD is pulled high, CLK is disabled and data is loaded from the shift register into the specified DAC register(s), updating the analog output(s). CMOS and TTL compatible.

CLK (Pin 8): Serial Interface Clock Input. CMOS and TTL compatible.

D_{IN} (Pin 9): Serial Interface Data Input. Data on the D_{IN} pin is shifted into the 16-bit register on the rising edge of CLK. CMOS and TTL compatible.

D_{OUT} (Pin 10): Serial Interface Data Output. Data appears on D_{OUT} 16 positive CLK edges after being applied to D_{IN} . May be tied to D_{IN} of another LTC1660 for daisy-chain operation. CMOS and TTL compatible.

CLR (Pin 11): Asynchronous Clear Input. All internal shift and DAC registers are cleared to zero at the falling edge of the CLR signal, forcing the analog outputs to zero scale. CMOS and TTL compatible.

V_{CC} (Pin 16): Supply Voltage Input. $2.7V \leq V_{CC} \leq 5.5V$.

DEFINITIONS

Differential Nonlinearity (DNL): The difference between the measured change and the ideal 1LSB change for any two adjacent codes. The DNL error between any two codes is calculated as follows:

$$DNL = (\Delta V_{OUT} - LSB)/LSB$$

Where ΔV_{OUT} is the measured voltage difference between two adjacent codes.

Digital Feedthrough: The glitch that appears at the analog output caused by AC coupling from the digital inputs when they change state. The area of the glitch is specified in (nV)(sec).

Full-Scale Error (FSE): The deviation of the actual full-scale voltage from ideal. FSE includes the effects of offset and gain errors (see Applications Information).

Integral Nonlinearity (INL): The deviation from a straight line passing through the endpoints of the DAC transfer curve (Endpoint INL). Because the output cannot go below zero, the linearity is measured between full scale and the lowest code which guarantees the output will be greater

than zero. The INL error at a given input code is calculated as follows:

$$INL = [V_{OUT} - V_{OS} - (V_{FS} - V_{OS})(code/1023)]/LSB$$

Where V_{OUT} is the output voltage of the DAC measured at the given input code.

Least Significant Bit (LSB): The ideal voltage difference between two successive codes.

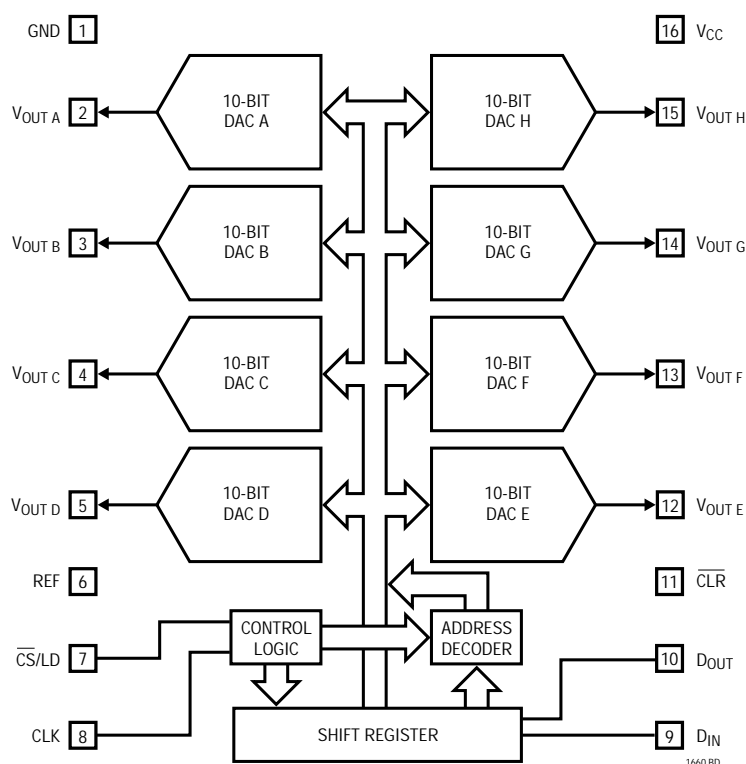

$$LSB = V_{REF}/1024$$

Resolution (n): Defines the number of DAC output states (2^n) that divide the full-scale range. Resolution does not imply linearity.

Voltage Offset Error (V_{OS}): Nominally, the voltage at the output when the DAC is loaded with all zeros. A single supply DAC can have a true negative offset, but the output cannot go below zero (see Applications Information).

For this reason, single supply DAC offset is measured at the lowest code that guarantees the output will be greater than zero.

BLOCK DIAGRAM

TIMING DIAGRAM

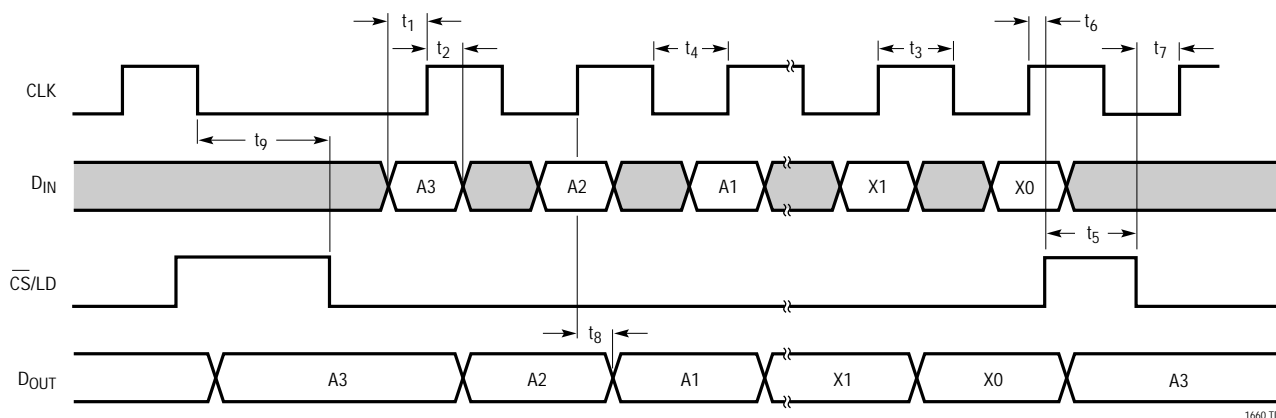

Figure 1

OPERATION

Transfer Function

The ideal transfer function for the LTC1660 is

$$V_{OUT(IDEAL)} = \left(\frac{k}{1024} \right) V_{REF}$$

where k is the decimal equivalent of the binary DAC input code D9-D0 and V_{REF} is the voltage at REF (Pin 6).

Serial Interface

Data on the D_{IN} input is shifted into the 16-bit register ($\overline{CS/LD}$ must be held low) on the positive edge of CLK. The 4-bit DAC address, A3-A0, is loaded first (see Table 2), then the 10-bit input code, D9-D0, ordered MSB-to-LSB in each case. Two don't-care bits, X1 and X0, are loaded last. When the full 16-bit word has been shifted in, $\overline{CS/LD}$ is pulled high, loading the DAC register with the word and causing the addressed DAC output(s) to update (see Figure 2). The clock is disabled internally when $\overline{CS/LD}$ is high. Note: CLK must be low before $\overline{CS/LD}$ is pulled low.

The buffered serial output of the shift register is available on the D_{OUT} pin, which swings from GND to V_{CC} . Data appears on D_{OUT} 16 positive CLK edges after being applied to D_{IN}.

Multiple LTC1660's can be controlled from a single 3-wire serial port (i.e., CLK, D_{IN} and $\overline{CS/LD}$) by using the included "daisy-chain" facility. A series of m chips is configured by

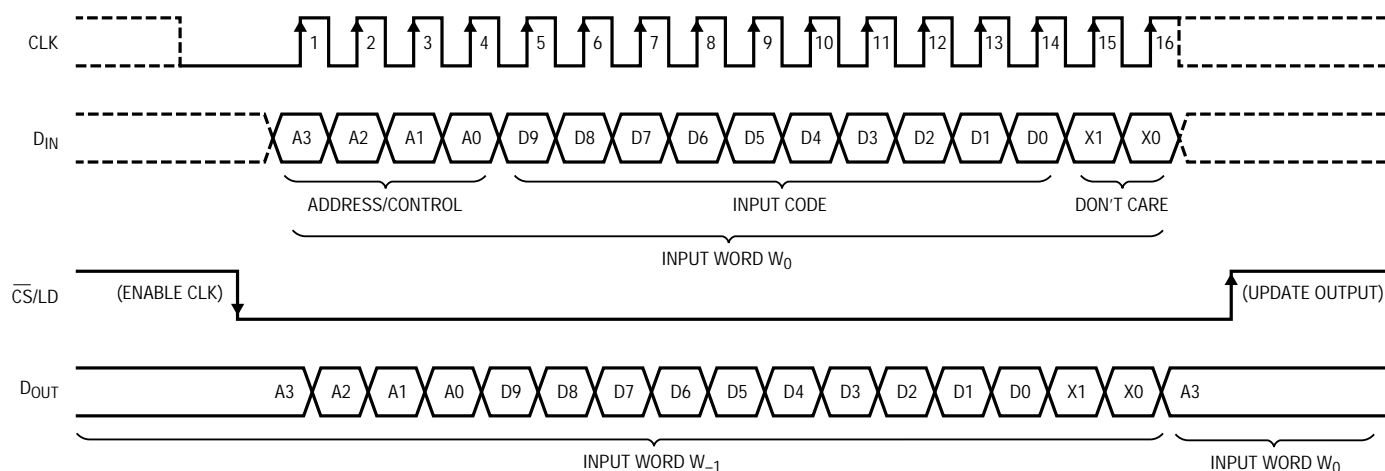

connecting each D_{OUT} (except the last) to D_{IN} of the next chip, forming a single 16 m -bit shift register. The CLK and $\overline{CS/LD}$ signals are common to all chips in the chain. In use, $\overline{CS/LD}$ is held low while m 16-bit words are clocked to D_{IN} of the first chip; $\overline{CS/LD}$ is then pulled high, updating all of them simultaneously.

Sleep Mode

DAC address 1110_b is reserved for the special Sleep instruction (see Table 2). In this mode, internal bias currents are disabled while all digital circuitry stays fully active; static power consumption is thus virtually eliminated. The analog outputs are set in a high impedance state and all DAC settings are retained in memory so that when Sleep mode is exited, the outputs of DACs not updated by the Wake command are restored to their last active state.

Sleep mode is initiated by performing a load sequence to address 1110_b (the DAC input word D9-D0 is ignored). Once in Sleep mode, a load sequence to any other address (including "No Change" addresses 0000_b and 1001-1101_b) causes the LTC1660 to Wake. It is possible to keep one or more chips of a daisy chain in continuous Sleep mode by giving the Sleep instruction to these chips each time the active chips in the chain are updated.

Voltage Outputs

Each of the eight rail-to-rail output amplifiers contained in the LTC1660 can source or sink up to 5mA. The outputs swing to within a few millivolts of either supply rail when unloaded and have an equivalent output resistance of 85Ω when driving a load to the rails. The output amplifiers are stable driving capacitive loads up to 1000pF.

A small resistor placed in series with the output can be used to achieve stability for any load capacitance. For example, a 0.1μF load can be successfully driven by inserting a 110Ω resistor. The phase margin of the resulting circuit is 45°, and increases monotonically from this point if larger values of resistance, capacitance or both are substituted for the values given.

1	1	1	1	Load ALL DACs with Same 10-Bit Code	Wake

APPLICATIONS INFORMATION

Rail-to-Rail Output Considerations

In any rail-to-rail DAC, the output swing is limited to voltages within the supply range.

If the DAC offset is negative, the output for the lowest codes limits at 0V as shown in Figure 3b.

Similarly, limiting can occur near full scale when the REF pin is tied to V_{CC} . If $V_{REF} = V_{CC}$ and the DAC full-scale error

(FSE) is positive, the output for the highest codes limits at V_{CC} as shown in Figure 3c. No full-scale limiting can occur if V_{REF} is less than $V_{CC} - FSE$.

Offset and linearity are defined and tested over the region of the DAC transfer function where no output limiting can occur.

Figure 3. Effects of Rail-to-Rail Operation On a DAC Transfer Curve. (a) Overall Transfer Function (b) Effect of Negative Offset for Codes Near Zero Scale (c) Effect of Positive Full-Scale Error for Input Codes Near Full Scale When $V_{REF} = V_{CC}$

PACKAGE DESCRIPTION
