

PIC17C75X

High-Performance 8-Bit CMOS EPROM Microcontrollers

Devices included in this data sheet:

- PIC17C752
- PIC17C756

Microcontroller Core Features:

- Only 58 single word instructions to learn
- All single cycle instructions (121 ns) except for program branches and table reads/writes which are two-cycle
- Operating speed:
 - ★ - DC - 33 MHz clock input
 - DC - 121 ns instruction cycle

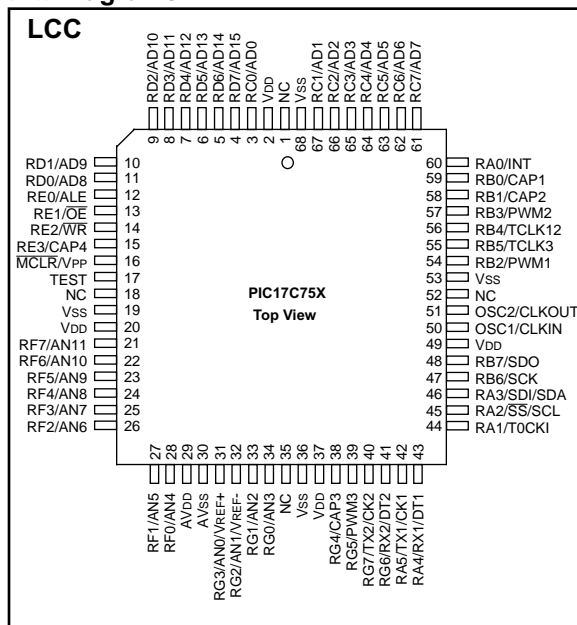

Device	Memory	
	Program (x16)	Data (x8)
PIC17C752	8K	454
PIC17C756	16K	902

- ★ • Hardware Multiplier
- Interrupt capability
- 16 level deep hardware stack
- Direct, indirect, and relative addressing modes
- Internal/external program memory execution
- Capable of addressing 64K x 16 program memory space

Peripheral Features:

- 50 I/O pins with individual direction control
- High current sink/source for direct LED drive
 - RA2 and RA3 are open drain, high voltage (12V), high current (60 mA), I/O pins
- Four capture input pins
 - Captures are 16-bit, max resolution 121 ns
- Three PWM outputs
 - PWM resolution is 1- to 10-bits
- TMR0: 16-bit timer/counter with 8-bit programmable prescaler
- TMR1: 8-bit timer/counter
- TMR2: 8-bit timer/counter
- TMR3: 16-bit timer/counter
- Two Universal Synchronous Asynchronous Receiver Transmitters (USART/SCI)
 - Independant baud rate generators
- 10-bit, 12 channel analog-to-digital converter
- Synchronous Serial Port (SSP) with SPI™ and I²C™ modes (including I²C master mode)

Pin Diagrams

Special Microcontroller Features:

- Power-on Reset (POR), Power-up Timer (PWRT) and Oscillator Start-up Timer (OST)
- Watchdog Timer (WDT) with its own on-chip RC oscillator for reliable operation
- Brown-out Reset
- Code-protection
- Power saving SLEEP mode
- Selectable oscillator options

CMOS Technology:

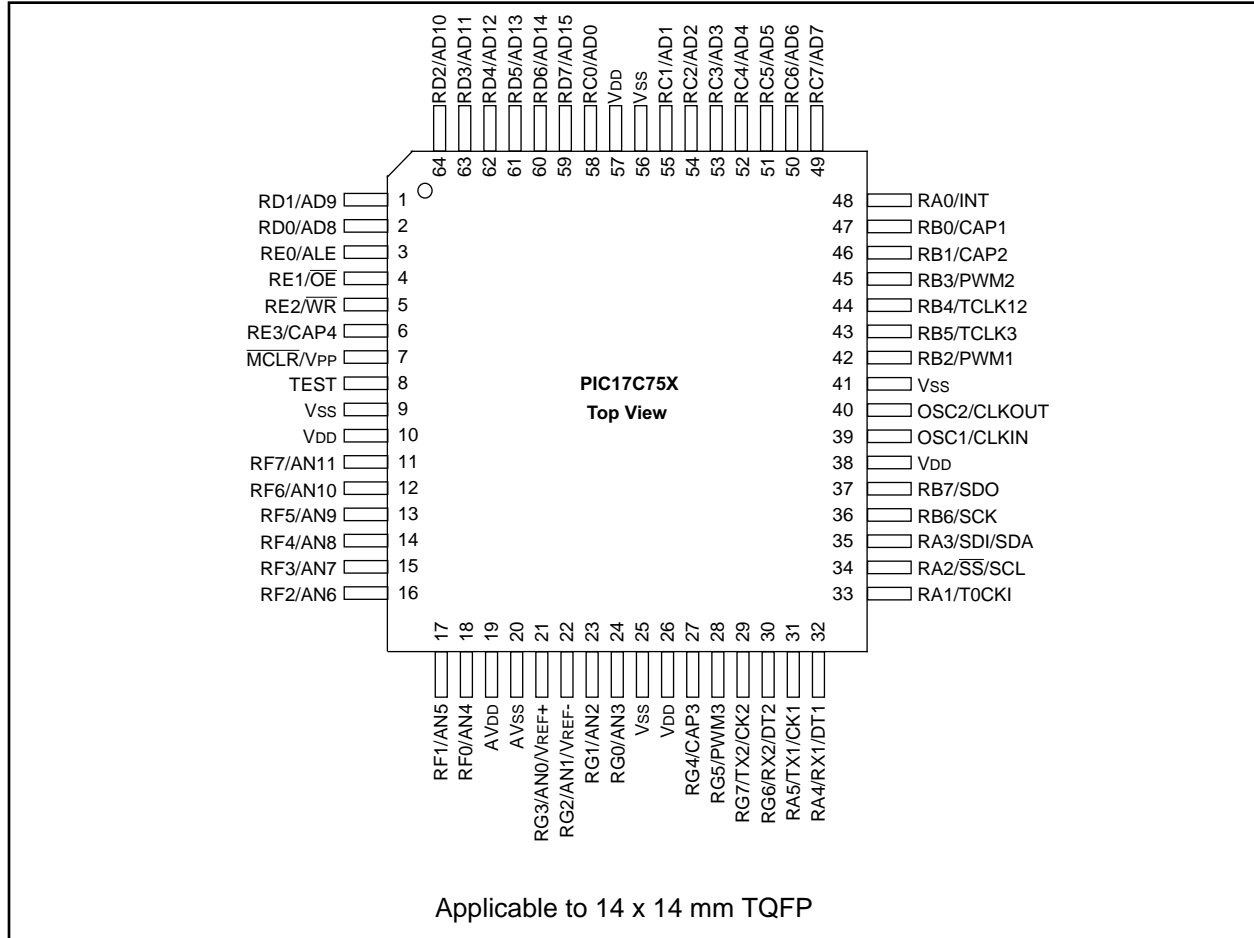

- Low-power, high-speed CMOS EPROM technology
- Fully static design
- Wide operating voltage range (2.5V to 6.0V)
- Commercial and Industrial temperature ranges
- Low-power consumption
 - < 5 mA @ 5V, 4 MHz
 - 100 µA typical @ 4.5V, 32 kHz
 - < 1 µA typical standby current @ 5V

To Our Valued Customers

We constantly strive to improve the quality of all our products and documentation. We have spent an exceptional amount of time to ensure that these documents are correct. However, we realize that we may have missed a few things. If you find any information that is missing or appears in error, please use the reader response form in the back of this data sheet to inform us. We appreciate your assistance in making this a better document.

1.0 OVERVIEW

This data sheet covers the PIC17C75X group of the PIC17CXXX family of microcontrollers. The following devices are discussed in this data sheet:

- PIC17C752
- PIC17C756

The PIC17C75X devices are 68-Pin, EPROM-based members of the versatile PIC17CXXX family of low-cost, high-performance, CMOS, fully-static, 8-bit microcontrollers.

All PIC16/17 microcontrollers employ an advanced RISC architecture. The PIC17CXXX has enhanced core features, 16-level deep stack, and multiple internal and external interrupt sources. The separate instruction and data buses of the Harvard architecture allow a 16-bit wide instruction word with a separate 8-bit wide data path. The two stage instruction pipeline allows all instructions to execute in a single cycle, except for program branches (which require two cycles). A total of 58 instructions (reduced instruction set) are available. Additionally, a large register set gives some of the architectural innovations used to achieve a very high performance. For mathematical intensive applications all devices have a single cycle 8 x 8 Hardware Multiplier.

PIC17CXXX microcontrollers typically achieve a 2:1 code compression and a 4:1 speed improvement over other 8-bit microcontrollers in their class.

PIC17C75X devices have up to 902 bytes of RAM and 50 I/O pins. In addition, the PIC17C75X adds several peripheral features useful in many high performance applications including:

- Four timer/counters
- Four capture inputs
- Three PWM outputs
- Two independent Universal Synchronous Asynchronous Receiver Transmitters (USARTs)
- An A/D converter (12 channel, 10-bit resolution)
- A Synchronous Serial Port (SPI and I²C w/ Master mode)

These special features reduce external components, thus reducing cost, enhancing system reliability and reducing power consumption.

There are four oscillator options, of which the single pin RC oscillator provides a low-cost solution, the LF oscillator is for low frequency crystals and minimizes power consumption, XT is a standard crystal, and the EC is for external clock input.

The SLEEP (power-down) mode offers additional power saving. Wake-up from SLEEP can occur through several external and internal interrupts and device resets.

A highly reliable Watchdog Timer with its own on-chip RC oscillator provides protection against software malfunction.

There are four configuration options for the device operational mode:

- Microprocessor
- Microcontroller
- Extended microcontroller
- Protected microcontroller

The microprocessor and extended microcontroller modes allow up to 64K-words of external program memory.

Brown-out Reset circuitry has also been added to the device. This allows a device reset to occur if the device VDD falls below the Brown-out voltage trip point (BVDD). The chip will remain in Brown-out Reset until VDD rises above BVDD.

Table 1-1 lists the features of the PIC17CXXX devices.

A UV-erasable CERQUAD-packaged version (compatible with PLCC) is ideal for code development while the cost-effective One-Time Programmable (OTP) version is suitable for production in any volume.

The PIC17C75X fits perfectly in applications that require extremely fast execution of complex software programs. These include applications ranging from precise motor control and industrial process control to automotive, instrumentation, and telecom applications.

The EPROM technology makes customization of application programs (with unique security codes, combinations, model numbers, parameter storage, etc.) fast and convenient. Small footprint package options (including die sales) make the PIC17C75X ideal for applications with space limitations that require high performance.

An In-circuit Serial Programming (ISP) feature allows:

- Flexibility of programming the software code as one of the last steps of the manufacturing process

High speed execution, powerful peripheral features, flexible I/O, and low power consumption all at low cost make the PIC17C75X ideal for a wide range of embedded control applications.

1.1 Family and Upward Compatibility

The PIC17CXXX family of microcontrollers have architectural enhancements over the PIC16C5X and PIC16CXX families. These enhancements allow the device to be more efficient in software and hardware requirements. Refer to Appendix A for a detailed list of enhancements and modifications. Code written for PIC16C5X or PIC16CXX can be easily ported to PIC17CXXX devices (Appendix B).

1.2 Development Support

The PIC17CXXX family is supported by a full-featured macro assembler, a software simulator, an in-circuit emulator, a universal programmer, a "C" compiler, and fuzzy logic support tools. For additional information see Section 19.0.

Note 1: Pins RA2 and RA3 can sink up to 60 mA.

2.0 DEVICE VARIETIES

Each device has a variety of frequency ranges and packaging options. Depending on application and production requirements, the proper device option can be selected using the information in the PIC17C75X Product Selection System section at the end of this data sheet. When placing orders, please use the "PIC17C75X Product Identification System" at the back of this data sheet to specify the correct part number. When discussing the functionality of the device, memory technology and voltage range does not matter.

There are three memory type options. These are specified in the middle characters of the part number.

1. **C**, as in PIC17**C**756. These devices have EPROM type memory.
2. **CR**, as in PIC17**CR**756. These devices have ROM type memory.
3. **F**, as in PIC17**F**756. These devices have Flash type memory.

All these devices operate over the standard voltage range. Devices are also offered which operate over an extended voltage range (and reduced frequency range). Table 2-1 shows all possible memory types and voltage range designators for a particular device. These designators are in **bold** typeface.

TABLE 2-1: DEVICE MEMORY VARIETIES

Memory Type	Voltage Range	
	Standard	Extended
EPROM	PIC17 C XXX	PIC17 LC XXX
ROM	PIC17 CR XXX	PIC17 LCR XXX
Flash	PIC17 F XXX	PIC17 LF XXX
Note: Not all memory technologies are available for a particular device.		

2.1 UV Erasable Devices

The UV erasable version, offered in CERQUAD package, is optimal for prototype development and pilot programs.

The UV erasable version can be erased and reprogrammed to any of the configuration modes. Microchip's programming of the PIC17C75X. Third party programmers also are available; refer to the *Third Party Guide* for a list of sources.

2.2 One-Time-Programmable (OTP) Devices

The availability of OTP devices is especially useful for customers expecting frequent code changes and updates.

The OTP devices, packaged in plastic packages, permit the user to program them once. In addition to the program memory, the configuration bits must be programmed.

2.3 Quick-Turnaround-Production (QTP) Devices

Microchip offers a QTP Programming Service for factory production orders. This service is made available for users who choose not to program a medium to high quantity of units and whose code patterns have stabilized. The devices are identical to the OTP devices but with all EPROM locations and configuration options already programmed by the factory. Certain code and prototype verification procedures apply before production shipments are available. Please contact your local Microchip Technology sales office for more details.

2.4 Serialized Quick-Turnaround Production (SQTPSM) Devices

Microchip offers a unique programming service where a few user-defined locations in each device are programmed with different serial numbers. The serial numbers may be random, pseudo-random or sequential.

Serial programming allows each device to have a unique number which can serve as an entry-code, password or ID number.

2.5 Read Only Memory (ROM) Devices

Microchip offers masked ROM versions of several of the highest volume parts, thus giving customers a low cost option for high volume, mature products.

ROM devices do not allow serialization information in the program memory space.

For information on submitting ROM code, please contact your regional sales office.

Note: Presently, NO ROM versions of the PIC17C75X devices are available.

2.6 Flash Memory Devices

These devices are electrically erasable and, therefore, can be offered in the low cost plastic package. Being electrically erasable, these devices can be erased and reprogrammed in-circuit. These devices are the same for prototype development, pilot programs, as well as production.

Note: Presently, NO Flash versions of the PIC17C75X devices are available.

3.0 ARCHITECTURAL OVERVIEW

The high performance of the PIC17CXXX can be attributed to a number of architectural features commonly found in RISC microprocessors. To begin with, the PIC17CXXX uses a modified Harvard architecture. This architecture has the program and data accessed from separate memories. So, the device has a program memory bus and a data memory bus. This improves bandwidth over traditional von Neumann architecture, where program and data are fetched from the same memory (accesses over the same bus). Separating program and data memory further allows instructions to be sized differently than the 8-bit wide data word. PIC17CXXX opcodes are 16-bits wide, enabling single word instructions. The full 16-bit wide program memory bus fetches a 16-bit instruction in a single cycle. A two-stage pipeline overlaps fetch and execution of instructions. Consequently, all instructions execute in a single cycle (121 ns @ 33 MHz), except for program branches and two special instructions that transfer data between program and data memory.

The PIC17CXXX can address up to 64K x 16 of program memory space.

The **PIC17C752** integrates 8K x 16 of EPROM program memory on-chip.

The **PIC17C756** integrates 16K x 16 EPROM program memory.

Program execution can be internal only (microcontroller or protected microcontroller mode), external only (microprocessor mode) or both (extended microcontroller mode). Extended microcontroller mode does not allow code protection.

The PIC17CXXX can directly or indirectly address its register files or data memory. All special function registers, including the Program Counter (PC) and Working Register (WREG), are mapped in the data memory. The PIC17CXXX has an orthogonal (symmetrical) instruction set that makes it possible to carry out any operation on any register using any addressing mode. This symmetrical nature and lack of 'special optimal situations' make programming with the PIC17CXXX simple yet efficient. In addition, the learning curve is reduced significantly.

One of the PIC17CXXX family architectural enhancements from the PIC16CXX family allows two file registers to be used in some two operand instructions. This allows data to be moved directly between two registers without going through the WREG register. Thus increasing performance and decreasing program memory usage.

The PIC17CXXX devices contain an 8-bit ALU and working register. The ALU is a general purpose arithmetic unit. It performs arithmetic and Boolean functions between data in the working register and any register file.

The ALU is 8-bits wide and capable of addition, subtraction, shift, and logical operations. Unless otherwise mentioned, arithmetic operations are two's complement in nature.

The WREG register is an 8-bit working register used for ALU operations.

All PIC17C75X devices have an 8 x 8 hardware multiplier. This multiplier generates a 16-bit result in a single cycle.

Depending on the instruction executed, the ALU may affect the values of the Carry (C), Digit Carry (DC), and Zero (Z) bits in the ALUSTA register. The C and DC bits operate as a borrow and digit borrow out bit, respectively, in subtraction. See the `SUBLW` and `SUBWF` instructions for examples.

Although the ALU does not perform signed arithmetic, the Overflow bit (OV) can be used to implement signed math. Signed arithmetic is comprised of a magnitude and a sign bit. The overflow bit indicates if the magnitude overflows and causes the sign bit to change state. That is if the result of the signed operation is greater than 128 (7Fh) or less than -127 (FFh). Signed math can have greater than 7-bit values (magnitude), if more than one byte is used. The use of the overflow bit only operates on bit6 (MSb of magnitude) and bit7 (sign bit) of the value in the ALU. That is, the overflow bit is not useful if trying to implement signed math where the magnitude, for example, is 11-bits. If the signed math values are greater than 7-bits (15-, 24- or 31-bit), the algorithm must ensure that the low order bytes ignore the overflow status bit.

Care should be taken when adding and subtracting signed numbers to ensure that the correct operation is executed. Example 3-1 shows an item that must be taken into account when doing signed arithmetic on an ALU which operates as an unsigned machine.

EXAMPLE 3-1: SIGNED MATH

Hex Value	Signed Value Math	Unsigned Value Math
FFh	-127	255
+ 01h	+ 1	+ 1
= ?	= -126 (FEh)	= 0 (00h); Carry bit = 1

Signed math requires the result to be FEh (-126). This would be accomplished by subtracting one as opposed to adding one.

A simplified block diagram is shown in Figure 3-1. The descriptions of the device pins are listed in Table 3-1.

† The output is only available by the Peripheral operation.

PIC17C75X

NOTES:

4.0 ON-CHIP OSCILLATOR CIRCUIT

The internal oscillator circuit is used to generate the device clock. Four device clock periods generate an internal instruction clock (Tcy). There are four modes that the oscillator can operate in. These are selected by the device configuration bits during device programming. These modes are:

- LF Low Frequency (FOSC ≤ 2 MHz)
- XT Standard Crystal/Resonator Frequency (2 MHz ≤ FOSC ≤ 33 MHz)
- EC External Clock Input (Default oscillator configuration)
- RC External Resistor/Capacitor (FOSC ≤ 4 MHz)

There are two timers that offer necessary delays on power-up. One is the Oscillator Start-up Timer (OST), intended to keep the chip in RESET until the crystal oscillator is stable. The other is the Power-up Timer (PWRT), which provides a fixed delay of 96 ms (nominal) on power-up only, designed to keep the part in RESET while the power supply stabilizes. With these two timers on-chip, most applications need no external reset circuitry.

SLEEP mode is designed to offer a very low current power-down mode. The user can wake from SLEEP through external reset, Watchdog Timer Reset or through an interrupt.

Several oscillator options are made available to allow the part to fit the application. The RC oscillator option saves system cost while the LF crystal option saves power. Configuration bits are used to select various options.

4.1 Oscillator Configurations

4.1.1 OSCILLATOR TYPES

The PIC17CXXX can be operated in four different oscillator modes. The user can program two configuration bits (FOSC1:FOSC0) to select one of these four modes:

- LF Low Power Crystal
- XT Crystal/Resonator
- EC External Clock Input
- RC Resistor/Capacitor

The main difference between the LF and XT modes is the gain of the internal inverter of the oscillator circuit which allows the different frequency ranges.

For more details on the device configuration bits, see Section 17.0.

4.1.2 CRYSTAL OSCILLATOR / CERAMIC RESONATORS

In XT or LF modes, a crystal or ceramic resonator is connected to the OSC1/CLKIN and OSC2/CLKOUT pins to establish oscillation (Figure 4-2). The PIC17CXXX oscillator design requires the use of a parallel cut crystal. Use of a series cut crystal may give a frequency out of the crystal manufacturers specifications.

For frequencies above 20 MHz, it is common for the crystal to be an overtone mode crystal. Use of overtone mode crystals require a tank circuit to attenuate the gain at the fundamental frequency. Figure 4-3 shows an example circuit.

4.1.2.1 OSCILLATOR / RESONATOR START-UP

As the device voltage increases from Vss, the oscillator will start its oscillations. The time required for the oscillator to start oscillating depends on many factors. These include:

- Crystal / resonator frequency
- Capacitor values used (C1 and C2)
- Device VDD rise time.
- System temperature
- Series resistor value (and type) if used
- Oscillator mode selection of device (which selects the gain of the internal oscillator inverter)

Figure 4-1 shows an example of a typical oscillator / resonator start-up. The peak-to-peak voltage of the oscillator waveform can be quite low (less than 50% of device VDD) when the waveform is centered at VDD/2 (refer to parameter number D033 and D043 in the electrical specification section).

FIGURE 4-1: OSCILLATOR / RESONATOR START-UP CHARACTERISTICS

PIC17C75X

FIGURE 4-2: CRYSTAL OR CERAMIC RESONATOR OPERATION (XT OR LF OSC CONFIGURATION)

TABLE 4-1: CAPACITOR SELECTION FOR CERAMIC RESONATORS

Oscillator Type	Resonator Frequency	Capacitor Range C1 = C2 (1)
LF	455 kHz	15 - 68 pF
	2.0 MHz	10 - 33 pF
XT	4.0 MHz	22 - 68 pF
	8.0 MHz	33 - 100 pF
	16.0 MHz	33 - 100 pF

Higher capacitance increases the stability of the oscillator but also increases the start-up time. These values are for design guidance only. Since each resonator has its own characteristics, the user should consult the resonator manufacturer for appropriate values of external components.

Note 1: These values include all board capacitances on this pin. Actual capacitor value depends on board capacitance

Resonators Used:

455 kHz	Panasonic EFO-A455K04B	± 0.3%
2.0 MHz	Murata Erie CSA2.00MG	± 0.5%
4.0 MHz	Murata Erie CSA4.00MG	± 0.5%
8.0 MHz	Murata Erie CSA8.00MT	± 0.5%
16.0 MHz	Murata Erie CSA16.00MX	± 0.5%

Resonators used did not have built-in capacitors.

FIGURE 4-3: CRYSTAL OPERATION, OVERTONE CRYSTALS (XT OSC CONFIGURATION)

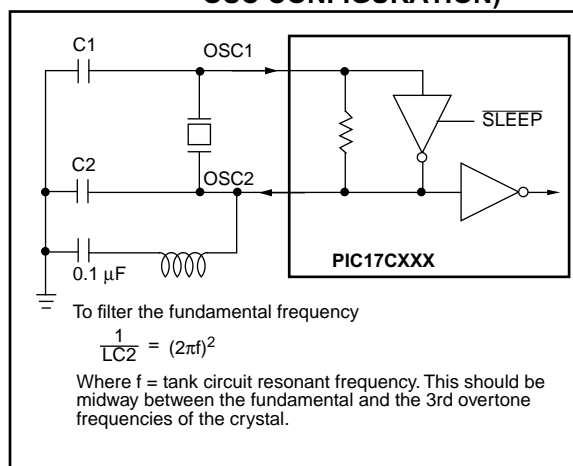

TABLE 4-2: CAPACITOR SELECTION FOR CRYSTAL OSCILLATOR

Osc Type	Freq	C1 (3)	C2 (3)
LF	32 kHz (1)	100-150 pF	100-150 pF
	1 MHz	10-33 pF	10-33 pF
	2 MHz	10-33 pF	10-33 pF
XT	2 MHz	47-100 pF	47-100 pF
	4 MHz	15-68 pF	15-68 pF
	8 MHz (2)	15-47 pF	15-47 pF
	16 MHz	TBD	TBD
	25 MHz	15-47 pF	15-47 pF
	32 MHz (3)	10	10

Higher capacitance increases the stability of the oscillator but also increases the start-up time and the oscillator current. These values are for design guidance only. Rs may be required in XT mode to avoid overdriving the crystals with low drive level specification. Since each crystal has its own characteristics, the user should consult the crystal manufacturer for appropriate values for external components.

Note 1: For VDD > 4.5V, C1 = C2 ≈ 30 pF is recommended.

2: Rs of 330Ω is required for a capacitor combination of 15/15 pF.

3: These values include all board capacitances on this pin. Actual capacitor value depends on board capacitance

Crystals Used:

32.768 kHz	Epson C-001R32.768K-A	± 20 PPM
1.0 MHz	ECS-10-13-1	± 50 PPM
2.0 MHz	ECS-20-20-1	± 50 PPM
4.0 MHz	ECS-40-20-1	± 50 PPM
8.0 MHz	ECS ECS-80-S-4 ECS-80-18-1	± 50 PPM
16.0 MHz	ECS-160-20-1	TBD
25 MHz	CTS CTS25M	± 50 PPM
32 MHz	CRYSTEK HF-2	± 50 PPM

4.1.3 EXTERNAL CLOCK OSCILLATOR

In the EC oscillator mode, the OSC1 input can be driven by CMOS drivers. In this mode, the OSC1/CLKIN pin is hi-impedance and the OSC2/CLKOUT pin is the CLKOUT output (4 T_{osc}).

FIGURE 4-4: EXTERNAL CLOCK INPUT OPERATION (EC OSC CONFIGURATION)

4.1.4 EXTERNAL CRYSTAL OSCILLATOR CIRCUIT

Either a prepackaged oscillator can be used or a simple oscillator circuit with TTL gates can be built. Prepackaged oscillators provide a wide operating range and better stability. A well-designed crystal oscillator will provide good performance with TTL gates. Two types of crystal oscillator circuits can be used: one with series resonance, or one with parallel resonance.

Figure 4-5 shows implementation of a parallel resonant oscillator circuit. The circuit is designed to use the fundamental frequency of the crystal. The 74AS04 inverter performs the 180-degree phase shift that a parallel oscillator requires. The 4.7 k Ω resistor provides the negative feedback for stability. The 10 k Ω potentiometer biases the 74AS04 in the linear region. This could be used for external oscillator designs.

FIGURE 4-5: EXTERNAL PARALLEL RESONANT CRYSTAL OSCILLATOR CIRCUIT

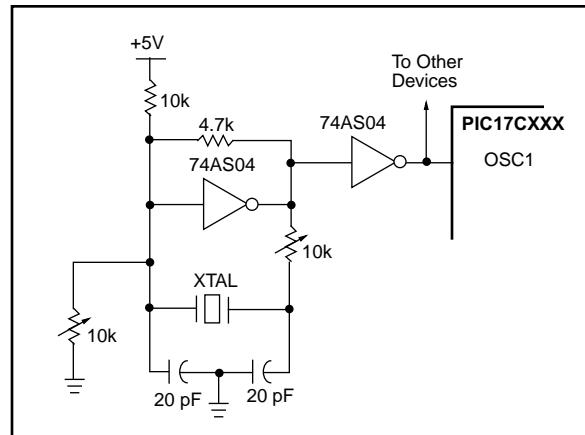

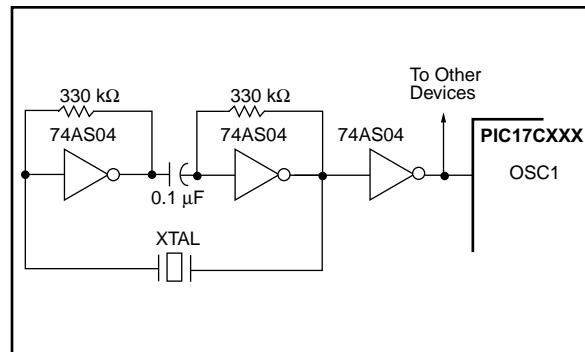

Figure 4-6 shows a series resonant oscillator circuit. This circuit is also designed to use the fundamental frequency of the crystal. The inverter performs a 180-degree phase shift in a series resonant oscillator circuit. The 330 k Ω resistors provide the negative feedback to bias the inverters in their linear region.

FIGURE 4-6: EXTERNAL SERIES RESONANT CRYSTAL OSCILLATOR CIRCUIT

4.1.5 RC OSCILLATOR

For timing insensitive applications, the RC device option offers additional cost savings. RC oscillator frequency is a function of the supply voltage, the resistor (R_{ext}) and capacitor (C_{ext}) values, and the operating temperature. In addition to this, oscillator frequency will vary from unit to unit due to normal process parameter variation. Furthermore, the difference in lead frame capacitance between package types will also affect oscillation frequency, especially for low C_{ext} values. The user also needs to take into account variation due to tolerance of external R and C components used. Figure 4-7 shows how the R/C combination is connected to the PIC17CXXX. For R_{ext} values below 2.2 k Ω , the oscillator operation may become unstable, or stop completely. For very high R_{ext} values (e.g. 1 M Ω), the oscillator becomes sensitive to noise, humidity and leakage. Thus, we recommend to keep R_{ext} between 3 k Ω and 100 k Ω .

Although the oscillator will operate with no external capacitor ($C_{ext} = 0$ pF), we recommend using values above 20 pF for noise and stability reasons. With little or no external capacitance, oscillation frequency can vary dramatically due to changes in external capacitances, such as PCB trace capacitance or package lead frame capacitance.

See Section 21.0 for RC frequency variation from part to part due to normal process variation. The variation is larger for larger R (since leakage current variation will affect RC frequency more for large R) and for smaller C (since variation of input capacitance will affect RC frequency more).

See Section 21.0 for variation of oscillator frequency due to V_{DD} for given R_{ext}/C_{ext} values as well as frequency variation due to operating temperature for given R, C, and V_{DD} values.

The oscillator frequency, divided by 4, is available on the OSC2/CLKOUT pin, and can be used for test purposes or to synchronize other logic (see Figure 4-8 for waveform).

FIGURE 4-7: RC OSCILLATOR MODE

4.1.5.1 RC START-UP

As the device voltage increases, the RC will immediately start its oscillations once the pin voltage levels meet the input threshold specifications (parameter number D032 and D042 in the electrical specification section). The time required for the RC to start oscillating depends on many factors. These include:

- Resistor value used
- Capacitor value used
- Device V_{DD} rise time
- System temperature

4.2 Clocking Scheme/Instruction Cycle

The clock input (from OSC1) is internally divided by four to generate four non-overlapping quadrature clocks, namely Q1, Q2, Q3, and Q4. Internally, the program counter (PC) is incremented every Q1, and the instruction is fetched from the program memory and latched into the instruction register in Q4. The instruction is decoded and executed during the following Q1 through Q4. The clocks and instruction execution flow are shown in Figure 4-8.

4.3 Instruction Flow/Pipelining

An "Instruction Cycle" consists of four Q cycles (Q1, Q2, Q3, and Q4). The instruction fetch and execute are pipelined such that fetch takes one instruction cycle while decode and execute takes another instruction cycle. However, due to the pipelining, each instruction effectively executes in one cycle. If an instruction causes the program counter to change (e.g. GOTO) then two cycles are required to complete the instruction (Example 4-1).

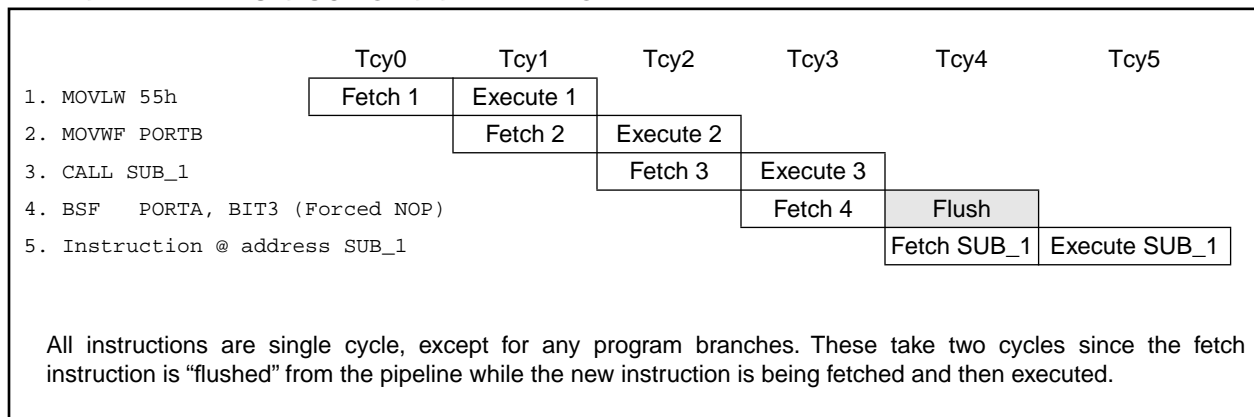

A fetch cycle begins with the program counter incrementing in Q1.

In the execution cycle, the fetched instruction is latched into the "Instruction Register (IR)" in cycle Q1. This instruction is then decoded and executed during the Q2, Q3, and Q4 cycles. Data memory is read during Q2 (operand read) and written during Q4 (destination write).

FIGURE 4-8: CLOCK/INSTRUCTION CYCLE

EXAMPLE 4-1: INSTRUCTION PIPELINE FLOW

PIC17C75X

NOTES:

5.0 RESET

The PIC17CXXX differentiates between various kinds of reset:

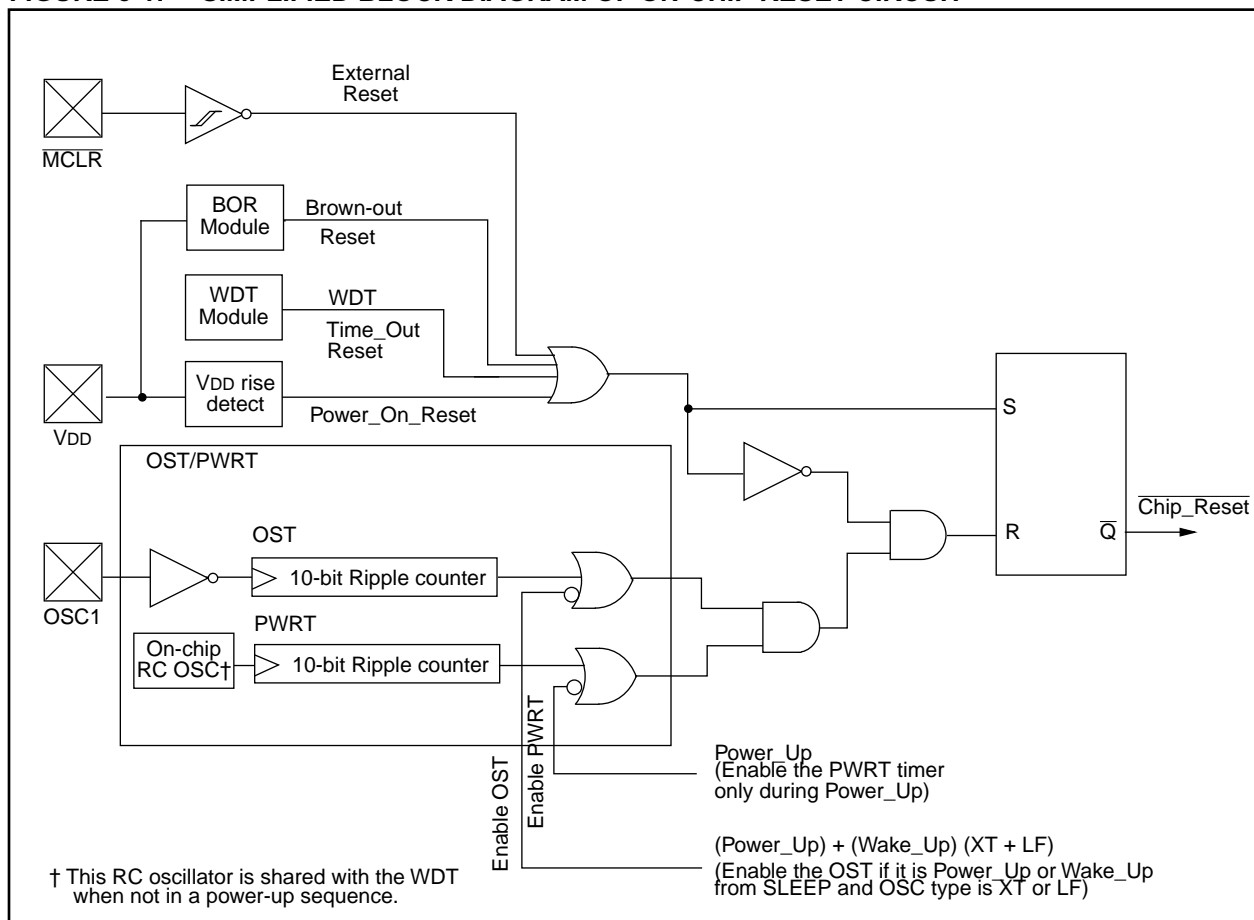

- Power-on Reset (POR)
- $\overline{\text{MCLR}}$ reset during normal operation
- Brown-out Reset
- WDT Reset (normal operation)

Some registers are not affected in any reset condition, their status is unknown on POR and unchanged in any other reset. Most other registers are forced to a "reset state" on Power-on Reset (POR), Brown-out Reset (BOR), on MCLR or WDT Reset and on MCLR reset during SLEEP. A WDT Reset during SLEEP, is viewed as the resumption of normal operation. The $\overline{\text{TO}}$ and $\overline{\text{PD}}$ bits are set or cleared differently in different reset situations as indicated in Table 5-3. These bits are used in software to determine the nature of the reset. See Table 5-4 for a full description of reset states of all registers.

Note: While the device is in a reset state, the internal phase clock is held in the Q1 state. Any processor mode that allows external execution will force the RE0/ALE pin as a low output and the RE1/ $\overline{\text{OE}}$ and RE2/ $\overline{\text{WR}}$ pins as high outputs.

A simplified block diagram of the on-chip reset circuit is shown in Figure 5-1.

FIGURE 5-1: SIMPLIFIED BLOCK DIAGRAM OF ON-CHIP RESET CIRCUIT

5.1 Power-on Reset (POR), Power-up Timer (PWRT), Oscillator Start-up Timer (OST), and Brown-out Reset (BOR)

5.1.1 POWER-ON RESET (POR)

The Power-on Reset circuit holds the device in reset until V_{DD} is above the trip point (in the range of 1.4V - 2.3V). The devices produce an internal reset for both rising and falling V_{DD} . To take advantage of the POR, just tie the \overline{MCLR}/V_{PP} pin directly (or through a resistor) to V_{DD} . This will eliminate external RC components usually needed to create Power-on Reset. A minimum rise time for V_{DD} is required. See Electrical Specifications for details.

Figure 5-2 and Figure 5-3 show two possible POR circuits.

FIGURE 5-2: USING ON-CHIP POR

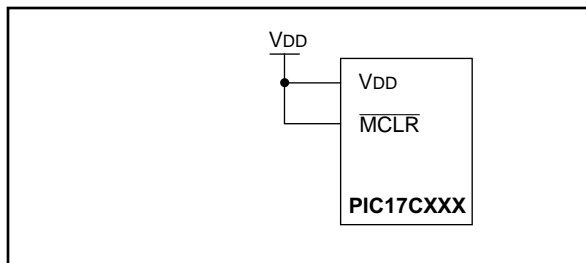

FIGURE 5-3: EXTERNAL POWER-ON RESET CIRCUIT (FOR SLOW V_{DD} POWER-UP)

- Note 1: An external Power-on Reset circuit is required only if V_{DD} power-up time is too slow. The diode D helps discharge the capacitor quickly when V_{DD} powers down.
- 2: $R < 40 \text{ k}\Omega$ is recommended to ensure that the voltage drop across R does not exceed 0.2V (max. leakage current spec. on the \overline{MCLR}/V_{PP} pin is 5 μA). A larger voltage drop will degrade V_{IH} level on the \overline{MCLR}/V_{PP} pin.
- 3: $R1 = 100\Omega$ to 1 $\text{k}\Omega$ will limit any current flowing into \overline{MCLR} from external capacitor C in the event of \overline{MCLR}/V_{PP} pin breakdown due to Electrostatic Discharge (ESD) or Electrical Overstress (EOS).

5.1.2 POWER-UP TIMER (PWRT)

The Power-up Timer provides a fixed 96 ms time-out (nominal) on power-up. This occurs from the rising edge of the POR signal and after the first rising edge of \overline{MCLR} (detected high). The Power-up Timer operates on an internal RC oscillator. The chip is kept in RESET as long as the PWRT is active. In most cases the PWRT delay allows V_{DD} to rise to an acceptable level.

The power-up time delay will vary from chip to chip and with V_{DD} and temperature. See DC parameters for details.

5.1.3 OSCILLATOR START-UP TIMER (OST)

The Oscillator Start-up Timer (OST) provides a 1024 oscillator cycle ($1024T_{osc}$) delay after \overline{MCLR} is detected high or a wake-up from SLEEP event occurs.

The OST time-out is invoked only for XT and LF oscillator modes on a Power-on Reset or a Wake-up from SLEEP.

The OST counts the oscillator pulses on the OSC1/CLKIN pin. The counter only starts incrementing after the amplitude of the signal reaches the oscillator input thresholds. This delay allows the crystal oscillator or resonator to stabilize before the device exits reset. The length of the time-out is a function of the crystal/resonator frequency.

Figure 5-4 shows the operation of the OST circuit. In this figure the oscillator is of such a low frequency that OST time out occurs after the power-up timer time-out.

FIGURE 5-4: OSCILLATOR START-UP TIME

5.1.4 TIME-OUT SEQUENCE

On power-up the time-out sequence is as follows: First the internal POR signal goes high when the POR trip point is reached. If MCLR is high, then both the OST and PWRT timers start. In general the PWRT time-out is longer, except with low frequency crystals/resonators. The total time-out also varies based on oscillator configuration. Table 5-1 shows the times that are associated with the oscillator configuration. Figure 5-5 and Figure 5-6 display these time-out sequences.

If the device voltage is not within electrical specification at the end of a time-out, the MCLR/VPP pin must be held low until the voltage is within the device specification. The use of an external RC delay is sufficient for many of these applications.

The time-out sequence begins from the first rising edge of MCLR.

Table 5-3 shows the reset conditions for some special registers, while Table 5-4 shows the initialization conditions for all the registers.

TABLE 5-1: TIME-OUT IN VARIOUS SITUATIONS

Oscillator Configuration	Power-up	Wake up from SLEEP	MCLR Reset	BOR
XT, LF	Greater of: 96 ms or 1024Tosc	1024Tosc	—	—
EC, RC	Greater of: 96 ms or 1024Tosc	—	—	—

TABLE 5-2: STATUS BITS AND THEIR SIGNIFICANCE

POR	BOR ⁽¹⁾	TO	PD	Event
0	0	1	1	Power-on Reset
1	1	1	0	MCLR Reset during SLEEP or interrupt wake-up from SLEEP
1	1	0	1	WDT Reset during normal operation
1	1	0	0	WDT Wake-up during SLEEP
1	1	1	1	MCLR Reset during normal operation
1	0	x	x	Brown-out Reset
0	0	0	x	Illegal, TO is set on POR
0	0	x	0	Illegal, PD is set on POR
x	x	1	1	CLRWDT instruction executed

Note 1: When BOR is enabled, else the BOR status bit is unknown

TABLE 5-3: RESET CONDITION FOR THE PROGRAM COUNTER AND THE CPUSTA REGISTER

Event		PCH:PCL	CPUSTA ⁽⁴⁾	OST Active
Power-on Reset		0000h	--11 1100	Yes
Brown-out Reset		0000h	--11 1101	No
MCLR Reset during normal operation		0000h	--11 1111	No
MCLR Reset during SLEEP		0000h	--11 1011	Yes ⁽²⁾
WDT Reset during normal operation		0000h	--11 0111	No
WDT Wake-up during SLEEP ⁽³⁾		0000h	--11 0011	Yes ⁽²⁾
Interrupt wake-up from SLEEP	GLINTD is set	PC + 1	--11 1011	Yes ⁽²⁾
	GLINTD is clear	PC + 1 ⁽¹⁾	--10 1011	Yes ⁽²⁾

Legend: u = unchanged, x = unknown, - = unimplemented read as '0'.

Note 1: On wake-up, this instruction is executed. The instruction at the appropriate interrupt vector is fetched and then executed.

2: The OST is only active when the Oscillator is configured for XT or LF modes.

3: The Program Counter = 0, that is, the device branches to the reset vector. This is different from the mid-range devices.

4: When BOR is enabled, else the BOR status bit is unknown.

PIC17C75X

In Figure 5-5, Figure 5-6 and Figure 5-7, $TPWRT > TOST$, as would be the case in higher frequency crystals. For lower frequency crystals, (i.e., 32 kHz) $TOST$ would be greater.

PRODH	19h	xxxx xxxx	uuuu uuuu	uuuu uuuu

Legend: u = unchanged, x = unknown, - = unimplemented read as '0', q = value depends on condition.

Note 1: One or more bits in INTSTA, PIR1, PIR2 will be affected (to cause wake-up).

- 2: When the wake-up is due to an interrupt and the GLINTD bit is cleared, the PC is loaded with the interrupt vector.
- 3: See Table 5-3 for reset value of specific condition.
- 4: If Brown-out is enabled, else the BOR bit is unknown.

5.1.5 BROWN-OUT RESET (BOR)

PIC17C75X devices have an on-chip Brown-out Reset circuitry. This circuitry places the device into a reset when the device voltage falls below a trip point (BVDD). This ensures that the device does not continue program execution outside the valid operation range of the device. Brown-out resets are typically used in AC line applications or large battery applications where large loads may be switched in (such as automotive).

Note: Before using the on-chip brown-out for a voltage supervisory function, please review the electrical specifications to ensure that they meet your requirements.

A configuration bit, BODEN, can disable (if clear/programmed) or enable (if set) the Brown-out Reset circuitry. If VDD falls below BVDD (Typically 4.0V, parameter D005 in electrical specification section), for greater than parameter D035, the brown-out situation will reset the chip. A reset is not guaranteed to occur if VDD falls below BVDD for less than parameter D035. The chip will remain in Brown-out Reset until VDD rises above BVDD. The Power-up Timer will now be invoked and will keep the chip in reset an additional 96 ms. If VDD drops below BVDD while the Power-up Timer is running, the chip will go back into a Brown-out Reset and the Power-up Timer will be initialized. Once VDD rises above BVDD, the Power-up Timer will execute a 96 ms time delay. Figure 5-10 shows typical Brown-out situations.

In some applications the Brown-out reset trip point of the device may not be at the desired level. Figure 5-8 and Figure 5-9 are two examples of external circuitry that may be implemented. Each needs to be evaluated to determine if they match the requirements of the application.

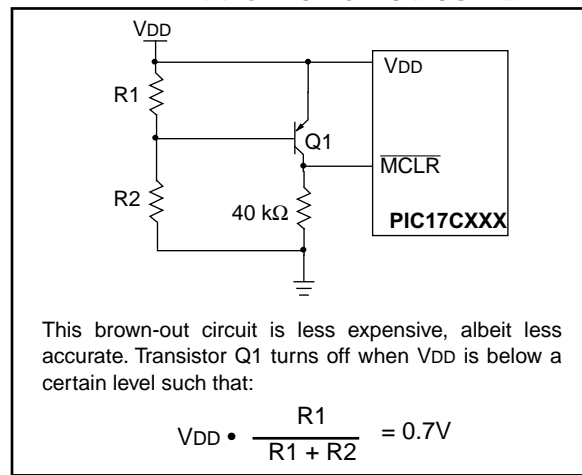

FIGURE 5-10: BROWN-OUT SITUATIONS

6.0 INTERRUPTS

The PIC17C75X devices have 18 sources of interrupt:

- External interrupt from the RA0/INT pin
- Change on RB7:RB0 pins
- TMR0 Overflow
- TMR1 Overflow
- TMR2 Overflow
- TMR3 Overflow
- USART1 Transmit buffer empty
- USART1 Receive buffer full
- USART2 Transmit buffer empty
- USART2 Receive buffer full
- SSP Interrupt
- SSP I²C bus collision interrupt
- A/D conversion complete
- Capture1
- Capture2
- Capture3
- Capture4
- T0CKI edge occurred

There are six registers used in the control and status of interrupts. These are:

- CPUSTA
- INTSTA
- PIE1
- PIR1
- PIE2
- PIR2

The CPUSTA register contains the GLINTD bit. This is the Global Interrupt Disable bit. When this bit is set, all interrupts are disabled. This bit is part of the controller core functionality and is described in the Memory Organization section.

When an interrupt is responded to, the GLINTD bit is automatically set to disable any further interrupts, the return address is pushed onto the stack and the PC is loaded with the interrupt vector address. There are four interrupt vectors. Each vector address is for a specific interrupt source (except the peripheral interrupts which all vector to the same address). These sources are:

- External interrupt from the RA0/INT pin
- TMR0 Overflow
- T0CKI edge occurred
- Any peripheral interrupt

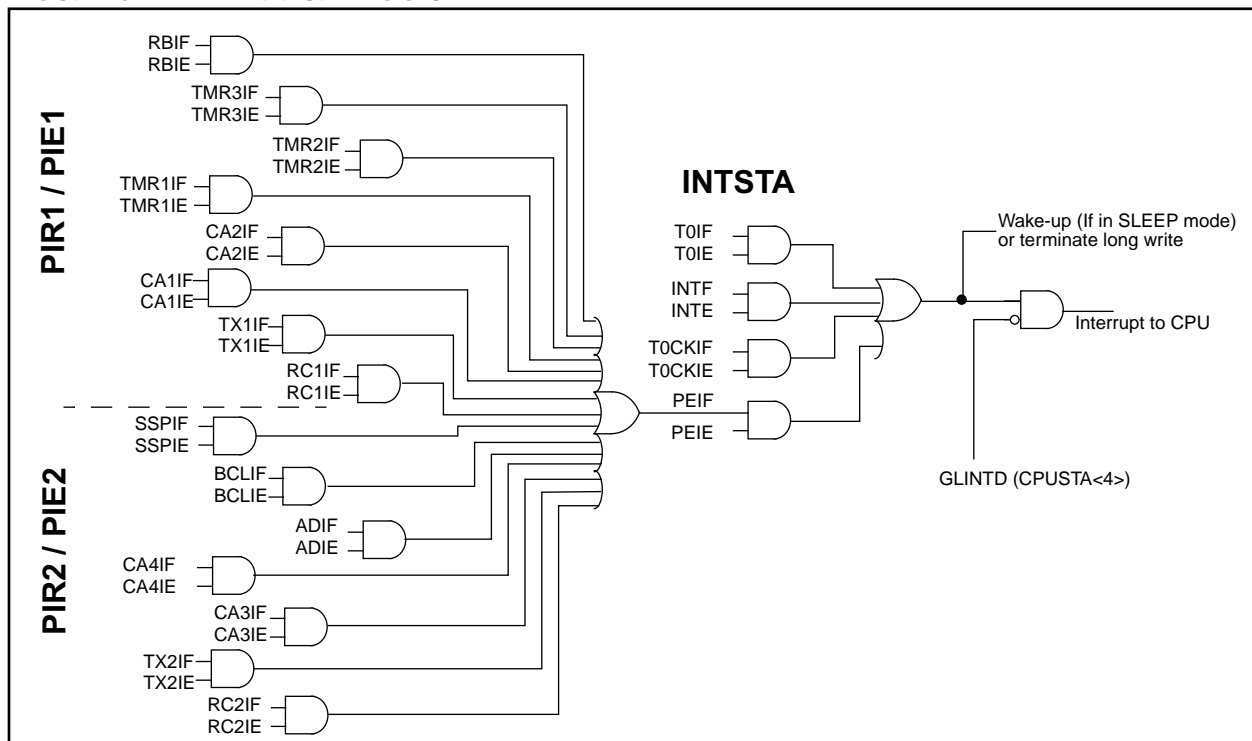

When program execution vectors to one of these interrupt vector addresses (except for the peripheral interrupts), the interrupt flag bit is automatically cleared. Vectoring to the peripheral interrupt vector address does not automatically clear the source of the interrupt. In the peripheral interrupt service routine, the source(s) of the interrupt can be determined by testing the interrupt flag bits. The interrupt flag bit(s) must be cleared in software before re-enabling interrupts to avoid infinite interrupt requests.

When an interrupt condition is met, that individual interrupt flag bit will be set regardless of the status of its corresponding mask bit or the GLINTD bit.

For external interrupt events, there will be an interrupt latency. For two cycle instructions, the latency could be one instruction cycle longer.

The “return from interrupt” instruction, `RETFIE`, can be used to mark the end of the interrupt service routine. When this instruction is executed, the stack is “POPed”, and the GLINTD bit is cleared (to re-enable interrupts).

FIGURE 6-1: INTERRUPT LOGIC

6.1 Interrupt Status Register (INTSTA)

The Interrupt Status/Control register (INTSTA) records the individual interrupt requests in flag bits, and contains the individual interrupt enable bits (not for the peripherals).

The PEIF bit is a read only, bit wise OR of all the peripheral flag bits in the PIR registers (Figure 6-5 and Figure 6-6).

Note: T0IF, INTF, T0CKIF, and PEIF get set by their specified condition, even if the corresponding interrupt enable bit is clear (interrupt disabled) or the GLINTD bit is set (all interrupts disabled).

Care should be taken when clearing any of the INTSTA register enable bits when interrupts are enabled (GLINTD is clear). If any of the INTSTA flag bits (T0IF, INTF, T0CKIF, or PEIF) are set in the same instruction cycle as the corresponding interrupt enable bit is cleared, the device will vector to the reset address (0x00).

When disabling any of the INTSTA enable bits, the GLINTD bit should be set (disabled).

6.3 Peripheral Interrupt Request Register1 (PIR1) and Register2 (PIR2)

These registers contains the individual flag bits for the peripheral interrupts.

Note: These bits will be set by the specified condition, even if the corresponding interrupt enable bit is cleared (interrupt disabled), or the GLINTD bit is set (all interrupts disabled). Before enabling an interrupt, the user may wish to clear the interrupt flag to ensure that the program does not immediately branch to the peripheral interrupt service routine.

SSPIF	BCLIF	ADIF	—	CA4IF	CA3IF	TX2IF	RC2IF
bit7						bit0	

R = Readable bit
W = Writable bit
-n = Value at POR reset

bit 7: **SSPIF**: Synchronous Serial Port (SSP) Interrupt Flag
 1 = The SSP interrupt condition has occurred, and must be cleared in software before returning from the interrupt service routine. The conditions that will set this bit are:
SPI
 A transmission/reception has taken place.
I²C Slave / Master
 A transmission/reception has taken place.
I²C Master
 The initiated start condition was completed by the SSP module.
 The initiated stop condition was completed by the SSP module.
 The initiated restart condition was completed by the SSP module.
 The initiated acknowledge condition was completed by the SSP module.
 A start condition occurred while the SSP module was idle (Multimaster system).
 A stop condition occurred while the SSP module was idle (Multimaster system).
 0 = An SSP interrupt condition has occurred.

bit 6: **BCLIF**: Bus Collision Interrupt Flag
 1 = A bus collision has occurred in the SSP, when configured for I²C master mode
 0 = No bus collision has occurred

bit 5: **ADIF**: A/D Module Interrupt Flag
 1 = An A/D conversion is complete
 0 = An A/D conversion is not complete

bit 4: **Unimplemented**: Read as '0'

bit 3: **CA4IF**: Capture4 Interrupt Flag
 1 = Capture event occurred on RE3/CAP4 pin
 0 = Capture event did not occur on RE3/CAP4 pin

bit 2: **CA3IF**: Capture3 Interrupt Flag
 1 = Capture event occurred on RG4/CAP3 pin
 0 = Capture event did not occur on RG4/CAP3 pin

bit 1: **TX2IF**: USART2 Transmit Interrupt Flag (State controlled by hardware)
 1 = USART2 Transmit buffer is empty
 0 = USART2 Transmit buffer is full

bit 0: **RC2IF**: USART2 Receive Interrupt Flag (State controlled by hardware)
 1 = USART2 Receive buffer is full
 0 = USART2 Receive buffer is empty

6.4 Interrupt Operation

Global Interrupt Disable bit, GLINTD (CPUSTA<4>), enables all unmasked interrupts (if clear) or disables all interrupts (if set). Individual interrupts can be disabled through their corresponding enable bits in the INTSTA register. Peripheral interrupts need either the global peripheral enable PEIE bit disabled, or the specific peripheral enable bit disabled. Disabling the peripherals via the global peripheral enable bit, disables all peripheral interrupts. GLINTD is set on reset (interrupts disabled).

The RETFIE instruction allows returning from interrupt and re-enables interrupts at the same time.

When an interrupt is responded to, the GLINTD bit is automatically set to disable any further interrupt, the return address is pushed onto the stack and the PC is loaded with the interrupt vector. There are four interrupt vectors which help reduce interrupt latency.

The peripheral interrupt vector has multiple interrupt sources. Once in the peripheral interrupt service routine, the source(s) of the interrupt can be determined by polling the interrupt flag bits. The peripheral interrupt flag bit(s) must be cleared in software before re-enabling interrupts to avoid continuous interrupts.

The PIC17C75X devices have four interrupt vectors. These vectors and their hardware priority are shown in Table 6-1. If two enabled interrupts occur "at the same time", the interrupt of the highest priority will be serviced first. This means that the vector address of that interrupt will be loaded into the program counter (PC).

TABLE 6-1: INTERRUPT VECTORS/PRIORITIES

Address	Vector	Priority
0008h	External Interrupt on RA0/INT pin (INTF)	1 (Highest)
0010h	TMR0 overflow interrupt (T0IF)	2
0018h	External Interrupt on T0CKI (T0CKIF)	3
0020h	Peripherals (PEIF)	4 (Lowest)

Note 1: Individual interrupt flag bits are set regardless of the status of their corresponding mask bit or the GLINTD bit.

Note 2: Before disabling any of the INTSTA enable bits, the GLINTD bit should be set (disabled).

6.5 RA0/INT Interrupt

The external interrupt on the RA0/INT pin is edge triggered. Either the rising edge, if INTEDG bit (T0STA<7>) is set, or the falling edge, if INTEDG bit is clear. When a valid edge appears on the RA0/INT pin, the INTF bit (INTSTA<4>) is set. This interrupt can be disabled by clearing the INTE control bit (INTSTA<0>). The INT interrupt can wake the processor from SLEEP. See Section 17.4 for details on SLEEP operation.

6.6 T0CKI Interrupt

The external interrupt on the RA1/T0CKI pin is edge triggered. Either the rising edge, if the T0SE bit (T0STA<6>) is set, or the falling edge, if the T0SE bit is clear. When a valid edge appears on the RA1/T0CKI pin, the T0CKIF bit (INTSTA<6>) is set. This interrupt can be disabled by clearing the T0CKIE control bit (INTSTA<2>). The T0CKI interrupt can wake up the processor from SLEEP. See Section 17.4 for details on SLEEP operation.

6.7 Peripheral Interrupt

The peripheral interrupt flag indicates that at least one of the peripheral interrupts occurred (PEIF is set). The PEIF bit is a read only bit, and is a bit wise OR of all the flag bits in the PIR registers AND'ed with the corresponding enable bits in the PIE registers. Some of the peripheral interrupts can wake the processor from SLEEP. See Section 17.4 for details on SLEEP operation.

6.8 Context Saving During Interrupts

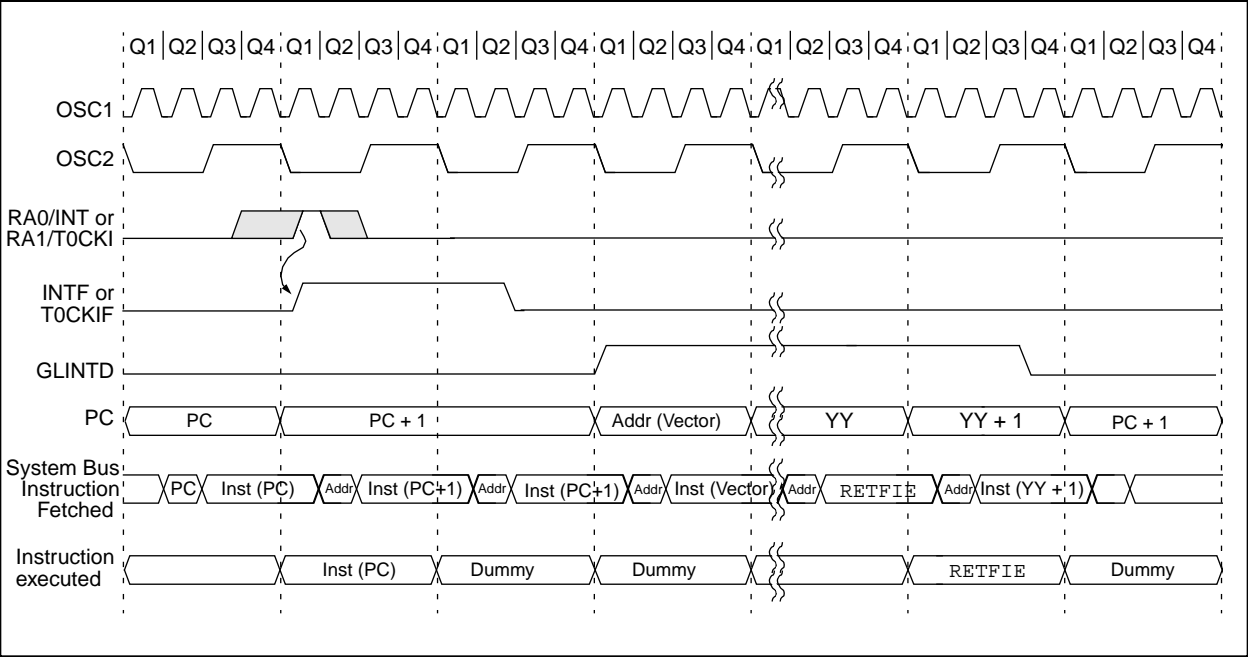

During an interrupt, only the returned PC value is saved on the stack. Typically, users may wish to save key registers during an interrupt; e.g. WREG, ALUSTA and the BSR registers. This requires implementation in software.

Example 6-2 shows the saving and restoring of information for an interrupt service routine. This is for a simple interrupt scheme, where only one interrupt may occur at a time (no interrupt nesting). The SFRs are stored in the non-banked GPR area.

Example 6-2 shows the saving and restoring of information for a more complex interrupt service routine. This is useful where nesting of interrupts is required. A maximum of 6 levels can be done by this example. The BSR is stored in the non-banked GPR area, while the other registers would be stored in a particular bank. Therefore 6 saves may be done with this routine (since there are 6 non-banked GPR registers). These routines require a dedicated indirect addressing register, FSR0 has been selected for this.

The PUSH and POP code segments could either be in each interrupt service routine or could be subroutines that were called. Depending on the application, other registers may also need to be saved.

FIGURE 6-7: INT PIN / T0CKI PIN INTERRUPT TIMING

EXAMPLE 6-1: SAVING STATUS AND WREG IN RAM (SIMPLE)

```

; The addresses that are used to store the CPUSTA and WREG values must be in the data memory
; address range of 1Ah - 1Fh. Up to 6 locations can be saved and restored using the MOVFP
; instruction. This instruction neither affects the status bits, nor corrupts the WREG register.
;
UNBANK1      EQU    0x01A      ; Address for 1st location to save
UNBANK2      EQU    0x01B      ; Address for 2nd location to save

```

7.0 MEMORY ORGANIZATION

There are two memory blocks in the PIC17C75X; program memory and data memory. Each block has its own bus, so that access to each block can occur during the same oscillator cycle.

The data memory can further be broken down into General Purpose RAM and the Special Function Registers (SFRs). The operation of the SFRs that control the "core" are described here. The SFRs used to control the peripheral modules are described in the section discussing each individual peripheral module.

7.1 Program Memory Organization

PIC17C75X devices have a 16-bit program counter capable of addressing a 64K x 16 program memory space. The reset vector is at 0000h and the interrupt vectors are at 0008h, 0010h, 0018h, and 0020h (Figure 7-1).

7.1.1 PROGRAM MEMORY OPERATION

The PIC17C75X can operate in one of four possible program memory configurations. The configuration is selected by configuration bits. The possible modes are:

- Microprocessor
- Microcontroller
- Extended Microcontroller
- Protected Microcontroller

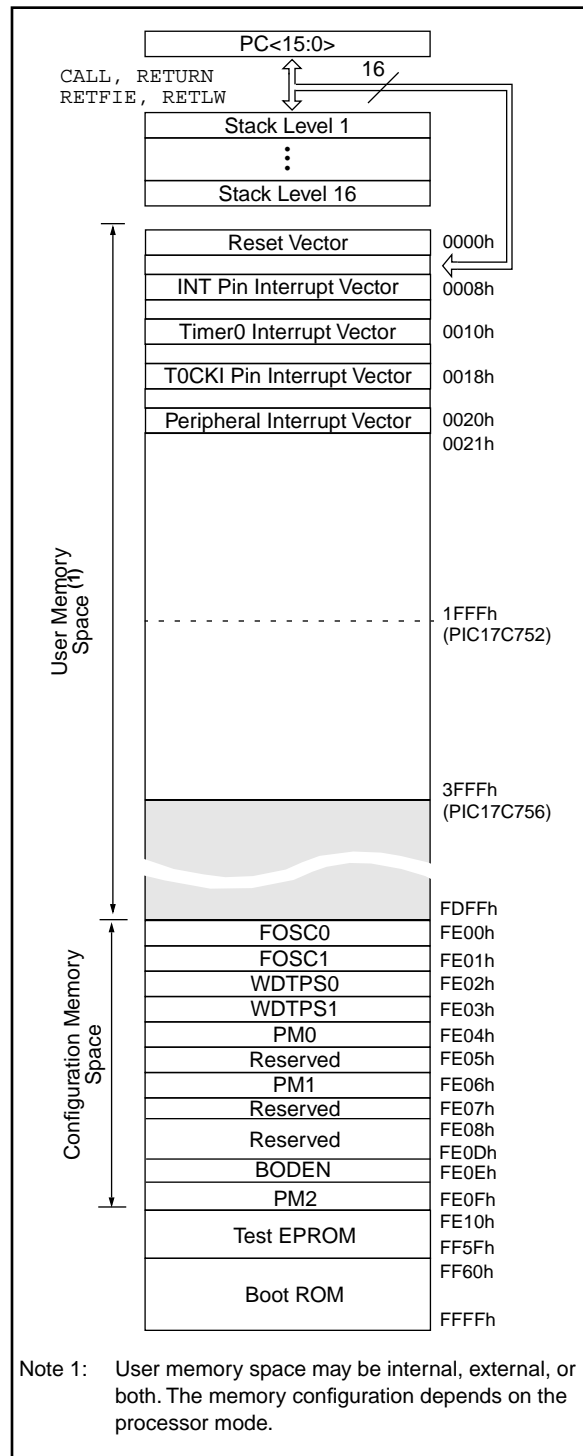

The microcontroller and protected microcontroller modes only allow internal execution. Any access beyond the program memory reads unknown data. The protected microcontroller mode also enables the code protection feature.

The extended microcontroller mode accesses both the internal program memory as well as external program memory. Execution automatically switches between internal and external memory. The 16-bits of address allow a program memory range of 64K-words.

The microprocessor mode only accesses the external program memory. The on-chip program memory is ignored. The 16-bits of address allow a program memory range of 64K-words. Microprocessor mode is the default mode of an unprogrammed device.

The different modes allow different access to the configuration bits, test memory, and boot ROM. Table 7-1 lists which modes can access which areas in memory. Test Memory and Boot Memory are not required for normal operation of the device. Care should be taken to ensure that no unintended branches occur to these areas.

FIGURE 7-1: PROGRAM MEMORY MAP AND STACK

PIC17C75X

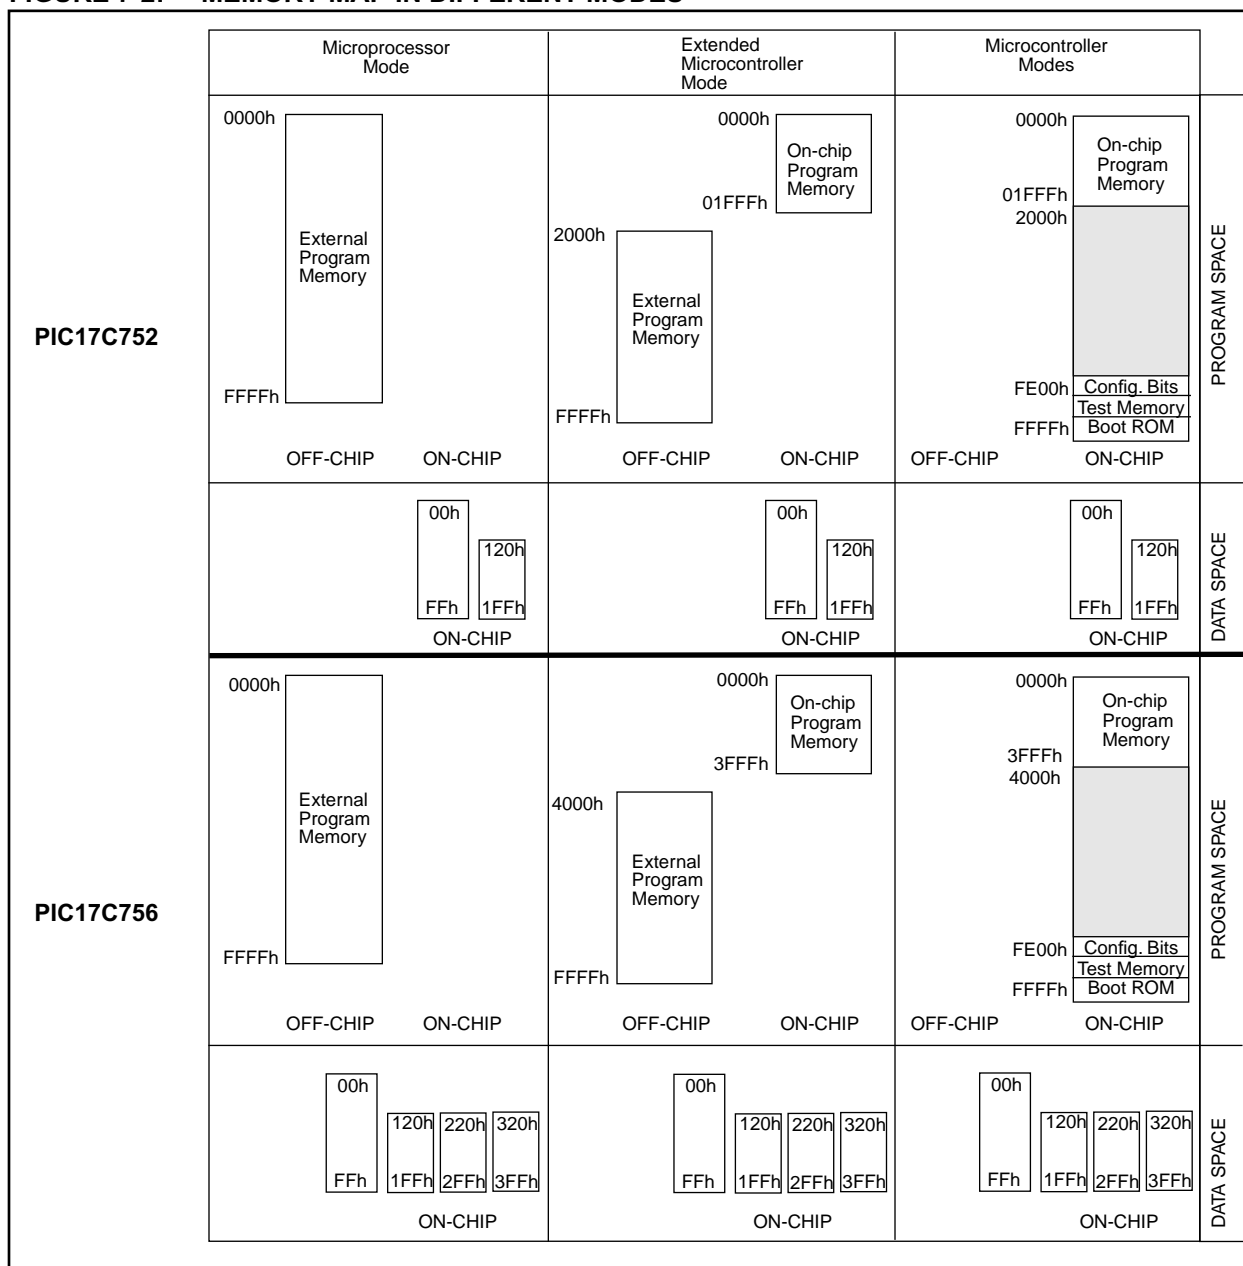

TABLE 7-1: MODE MEMORY ACCESS

Operating Mode	Internal Program Memory	Configuration Bits, Test Memory, Boot ROM
Microprocessor	No Access	No Access
Microcontroller	Access	Access
Extended Microcontroller	Access	No Access
Protected Microcontroller	Access	Access

The PIC17C75X can operate in modes where the program memory is off-chip. They are the microprocessor and extended microcontroller modes. The microprocessor mode is the default for an unprogrammed device.

Regardless of the processor mode, data memory is always on-chip.

FIGURE 7-2: MEMORY MAP IN DIFFERENT MODES

7.1.2 EXTERNAL MEMORY INTERFACE

When either microprocessor or extended microcontroller mode is selected, PORTC, PORTD and PORTE are configured as the system bus. PORTC and PORTD are the multiplexed address/data bus and PORTE<2:0> is for the control signals. External components are needed to demultiplex the address and data. This can be done as shown in Figure 7-4. The waveforms of address and data are shown in Figure 7-3. For complete timings, please refer to the electrical specification section.

FIGURE 7-3: EXTERNAL PROGRAM MEMORY ACCESS WAVEFORMS

The system bus requires that there is no bus conflict (minimal leakage), so the output value (address) will be capacitively held at the desired value.

As the speed of the processor increases, external EPROM memory with faster access time must be used. Table 7-2 lists external memory speed requirements for a given PIC17C75X device frequency.

In extended microcontroller mode, when the device is executing out of internal memory, the control signals will continue to be active. That is, they indicate the action that is occurring in the internal memory. The external memory access is ignored.

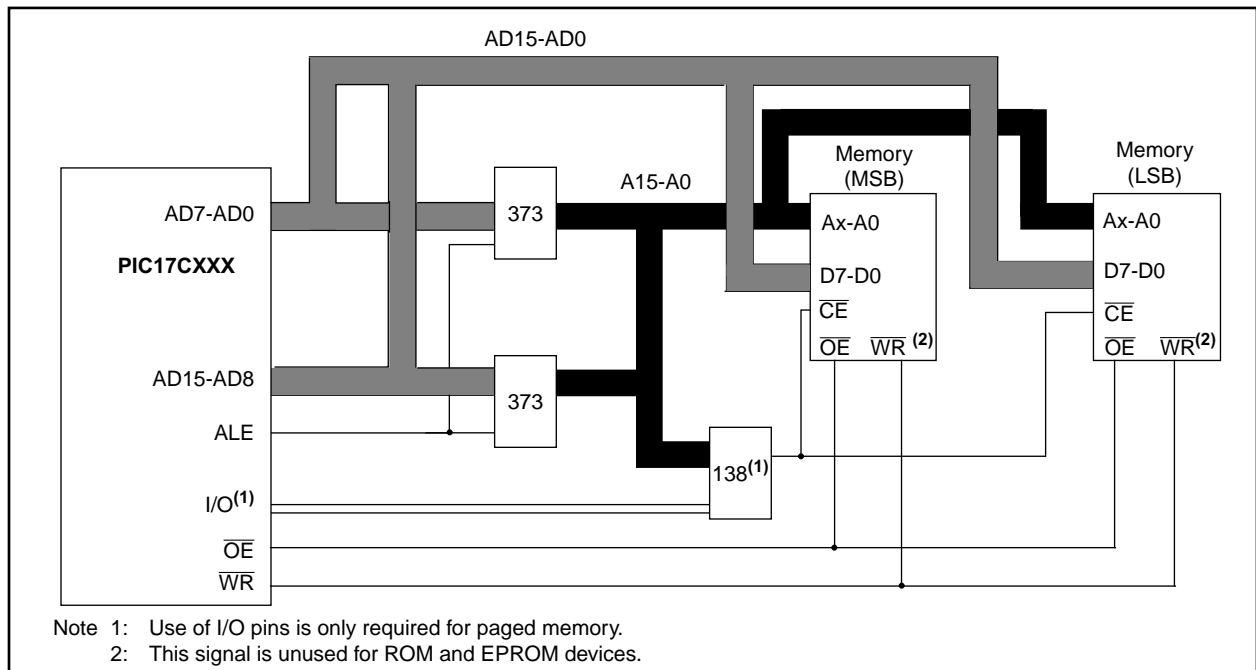

This following selection is for use with Microchip EPROMs. For interfacing to other manufacturers memory, please refer to the electrical specifications of the desired PIC17C75X device, as well as the desired memory device to ensure compatibility.

TABLE 7-2: EPROM MEMORY ACCESS TIME ORDERING SUFFIX

PIC17C75X Oscillator Frequency	Instruction Cycle Time (Tcy)	EPROM Suffix
		PIC17C752 PIC17C756
8 MHz	500 ns	-25
16 MHz	250 ns	-15
20 MHz	200 ns	-10
25 MHz	160 ns	-70
33 MHz	121 ns	(1)

Note 1: The access times for this requires the use of fast SRAMs.

FIGURE 7-4: TYPICAL EXTERNAL PROGRAM MEMORY CONNECTION DIAGRAM

7.2 Data Memory Organization

Data memory is partitioned into two areas. The first is the General Purpose Registers (GPR) area, while the second is the Special Function Registers (SFR) area. The SFRs control and give the status for the operation of the device.

Portions of data memory are banked, this occurs in both areas. The GPR area is banked to allow greater than 232 bytes of general purpose RAM.

Banking requires the use of control bits for bank selection. These control bits are located in the Bank Select Register (BSR). If an access is made to the unbanked region, the BSR bits are ignored. Figure 7-5 shows the data memory map organization.

Instructions `MOVPF` and `MOVFP` provide the means to move values from the peripheral area ("P") to any location in the register file ("F"), and vice-versa. The definition of the "P" range is from 0h to 1Fh, while the "F" range is 0h to FFh. The "P" range has six more locations than peripheral registers which can be used as General Purpose Registers. This can be useful in some applications where variables need to be copied to other locations in the general purpose RAM (such as saving status information during an interrupt).

The entire data memory can be accessed either directly or indirectly through file select registers FSR0 and FSR1 (Section 7.4). Indirect addressing uses the appropriate control bits of the BSR for accesses into the banked areas of data memory. The BSR is explained in greater detail in Section 7.8.

7.2.1 GENERAL PURPOSE REGISTER (GPR)

All devices have some amount of GPR area. The GPRs are 8-bits wide. When the GPR area is greater than 232, it must be banked to allow access to the additional memory space.

All the PIC17C75X devices have banked memory in the GPR area. To facilitate switching between these banks, the `MOVLR` bank instruction has been added to the instruction set. GPRs are not initialized by a Power-on Reset and are unchanged on all other resets.

7.2.2 SPECIAL FUNCTION REGISTERS (SFR)

The SFRs are used by the CPU and peripheral functions to control the operation of the device (Figure 7-5). These registers are static RAM.

The SFRs can be classified into two sets, those associated with the "core" function and those related to the peripheral functions. Those registers related to the "core" are described here, while those related to a peripheral feature are described in the section for each peripheral feature.

The peripheral registers are in the banked portion of memory, while the core registers are in the unbanked region. To facilitate switching between the peripheral banks, the `MOVLB` bank instruction has been provided.

3: Other (non power-up) resets include: external reset through \overline{MCLR} and Watchdog Timer Reset.

7.2.2.1 ALU STATUS REGISTER (ALUSTA)

The ALUSTA register contains the status bits of the Arithmetic and Logic Unit and the mode control bits for the indirect addressing register.

As with all the other registers, the ALUSTA register can be the destination for any instruction. If the ALUSTA register is the destination for an instruction that affects the Z, DC or C bits, then the write to these three bits is disabled. These bits are set or cleared according to the device logic. Therefore, the result of an instruction with the ALUSTA register as destination may be different than intended.

For example, `CLRF ALUSTA` will clear the upper four bits and set the Z bit. This leaves the ALUSTA register as `0000u1uu` (where u = unchanged).

It is recommended, therefore, that only `BCF`, `BSF`, `SWAPF` and `MOVWF` instructions be used to alter the ALUSTA register because these instructions do not

affect any status bit. To see how other instructions affect the status bits, see the "Instruction Set Summary."

Note 3: The C and DC bits operate as a borrow and digit borrow bit, respectively, in subtraction. See the `SUBLW` and `SUBWF` instructions for examples.

Note 4: The overflow bit will be set if the 2's complement result exceeds +127 or is less than -128.

The Arithmetic and Logic Unit (ALU) is capable of carrying out arithmetic or logical operations on two operands or a single operand. All single operand instructions operate either on the WREG register or the given file register. For two operand instructions, one of the operands is the WREG register and the other one is either a file register or an 8-bit immediate constant.

FIGURE 7-6: ALUSTA REGISTER (ADDRESS: 04h, UNBANKED)

R/W - 1	R/W - 1	R/W - 1	R/W - 1	R/W - x	R/W - x	R/W - x	R/W - x
FS3	FS2	FS1	FS0	OV	Z	DC	C
bit7							bit0

R = Readable bit
W = Writable bit
-n = Value at POR reset
(x = unknown)

bit 7-6: **FS3:FS2:** FSR1 Mode Select bits
 00 = Post auto-decrement FSR1 value
 01 = Post auto-increment FSR1 value
 1x = FSR1 value does not change

bit 5-4: **FS1:FS0:** FSR0 Mode Select bits
 00 = Post auto-decrement FSR0 value
 01 = Post auto-increment FSR0 value
 1x = FSR0 value does not change

bit 3: **OV:** Overflow bit
 This bit is used for signed arithmetic (2's complement). It indicates an overflow of the 7-bit magnitude, which causes the sign bit (bit7) to change state.
 1 = Overflow occurred for signed arithmetic, (in this arithmetic operation)
 0 = No overflow occurred

bit 2: **Z:** Zero bit
 1 = The result of an arithmetic or logic operation is zero
 0 = The results of an arithmetic or logic operation is not zero

bit 1: **DC:** Digit carry/borrow bit
 For `ADDWF` and `ADDLW` instructions.
 1 = A carry-out from the 4th low order bit of the result occurred
 0 = No carry-out from the 4th low order bit of the result
 Note: For borrow the polarity is reversed.

bit 0: **C:** carry/borrow bit
 For `ADDWF` and `ADDLW` instructions.
 1 = A carry-out from the most significant bit of the result occurred
 Note that a subtraction is executed by adding the two's complement of the second operand. For rotate (`RRCF`, `RLCF`) instructions, this bit is loaded with either the high or low order bit of the source register.
 0 = No carry-out from the most significant bit of the result
 Note: For borrow the polarity is reversed.

7.2.2.2 CPU STATUS REGISTER (CPUSTA)

The CPUSTA register contains the status and control bits for the CPU. This register has a bit that is used to globally enable/disable interrupts. If only a specific interrupt is desired to be enabled/disabled, please refer to the Interrupt Status (INTSTA) register and the Peripheral Interrupt Enable (PIE) registers. The CPUSTA register also indicates if the stack is available and contains the Power-down (\overline{PD}) and Time-out (\overline{TO}) bits. The \overline{TO} , \overline{PD} , and STKAV bits are not writable. These bits are set and cleared according to device logic. Therefore, the result of an instruction with the CPUSTA register as destination may be different than intended.

The \overline{POR} bit allows the differentiation between a Power-on Reset, external \overline{MCLR} reset, or a WDT Reset. The BOR bit indicates if a Brown-out Reset occurred.

Note 1: The \overline{BOR} status bit is a don't care and is not necessarily predictable if the brown-out circuit is disabled (when the BODEN bit in the Configuration word is programmed).

FIGURE 7-7: CPUSTA REGISTER (ADDRESS: 06h, UNBANKED)

U - 0	U - 0	R - 1	R/W - 1	R - 1	R - 1	R/W - 0	R/W - 0
—	—	STKAV	GLINTD	\overline{TO}	\overline{PD}	\overline{POR}	\overline{BOR}
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, Read as '0'
- n = Value at POR reset

bit 7-6: **Unimplemented:** Read as '0'

bit 5: **STKAV:** Stack Available bit
This bit indicates that the 4-bit stack pointer value is Fh, or has rolled over from Fh → 0h (stack overflow).
1 = Stack is available
0 = Stack is full, or a stack overflow may have occurred (Once this bit has been cleared by a stack overflow, only a device reset will set this bit)

bit 4: **GLINTD:** Global Interrupt Disable bit
This bit disables all interrupts. When enabling interrupts, only the sources with their enable bits set can cause an interrupt.
1 = Disable all interrupts
0 = Enables all un-masked interrupts

bit 3: **\overline{TO} :** WDT Time-out Status bit
1 = After power-up or by a CLRWD \overline{T} instruction
0 = A Watchdog Timer time-out occurred

bit 2: **\overline{PD} :** Power-down Status bit
1 = After power-up or by the CLRWD \overline{T} instruction
0 = By execution of the SLEEP instruction

bit 1: **\overline{POR} :** Power-on Reset Status bit
1 = No Power-on Reset occurred
0 = A Power-on Reset occurred (must be set by software after a Power-on Reset occurs)

bit 0: **\overline{BOR} :** Brown-out Reset Status bit
1 = No Brown-out Reset occurred
0 = A Brown-out Reset occurred (must be set by software after a Brown-out Reset occurs)

7.2.2.3 TMR0 STATUS/CONTROL REGISTER (T0STA)

This register contains various control bits. Bit7 (INTEDG) is used to control the edge upon which a signal on the RA0/INT pin will set the RA0/INT interrupt flag. The other bits configure the Timer0 prescaler and clock source.

FIGURE 7-8: T0STA REGISTER (ADDRESS: 05h, UNBANKED)

R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	U - 0
INTEDG	T0SE	T0CS	T0PS3	T0PS2	T0PS1	T0PS0	—
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented, reads as '0'
-n = Value at POR reset

bit 7: **INTEDG:** RA0/INT Pin Interrupt Edge Select bit
This bit selects the edge upon which the interrupt is detected.
1 = Rising edge of RA0/INT pin generates interrupt
0 = Falling edge of RA0/INT pin generates interrupt

bit 6: **T0SE:** Timer0 Clock Input Edge Select bit
This bit selects the edge upon which TMR0 will increment.
When T0CS = 0 (External Clock)
1 = Rising edge of RA1/T0CKI pin increments TMR0 and/or generates a T0CKIF interrupt
0 = Falling edge of RA1/T0CKI pin increments TMR0 and/or generates a T0CKIF interrupt
When T0CS = 1 (Internal Clock)
Don't care

bit 5: **T0CS:** Timer0 Clock Source Select bit
This bit selects the clock source for Timer0.
1 = Internal instruction clock cycle (Tcy)
0 = External clock input on the T0CKI pin

bit 4-1: **T0PS3:T0PS0:** Timer0 Prescale Selection bits
These bits select the prescale value for Timer0.

T0PS3:T0PS0	Prescale Value
0000	1:1
0001	1:2
0010	1:4
0011	1:8
0100	1:16
0101	1:32
0110	1:64
0111	1:128
1xxx	1:256

bit 0: **Unimplemented:** Read as '0'

7.3 Stack Operation

PIC17C75X devices have a 16 x 16-bit hardware stack (Figure 7-1). The stack is not part of either the program or data memory space, and the stack pointer is neither readable nor writable. The PC (Program Counter) is "PUSHed" onto the stack when a CALL or LCALL instruction is executed or an interrupt is acknowledged. The stack is "POPed" in the event of a RETURN, RETLW, or a RETFIE instruction execution. PCLATH is not affected by a "PUSH" or a "POP" operation.

The stack operates as a circular buffer, with the stack pointer initialized to '0' after all resets. There is a stack available bit (STKAV) to allow software to ensure that the stack has not overflowed. The STKAV bit is set after a device reset. When the stack pointer equals Fh, STKAV is cleared. When the stack pointer rolls over from Fh to 0h, the STKAV bit will be held clear until a device reset.

Note 1: There is not a status bit for stack underflow. The STKAV bit can be used to detect the underflow which results in the stack pointer being at the top of stack.

Note 2: There are no instruction mnemonics called PUSH or POP. These are actions that occur from the execution of the CALL, RETURN, RETLW, and RETFIE instructions, or the vectoring to an interrupt vector.

Note 3: After a reset, if a "POP" operation occurs before a "PUSH" operation, the STKAV bit will be cleared. This will appear as if the stack is full (underflow has occurred). If a "PUSH" operation occurs next (before another "POP"), the STKAV bit will be locked clear. Only a device reset will cause this bit to set.

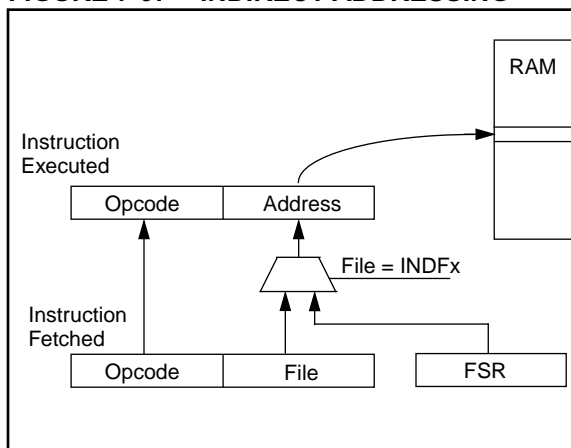

After the device is "PUSHed" sixteen times (without a "POP"), the seventeenth push overwrites the value from the first push. The eighteenth push overwrites the second push (and so on).

7.4 Indirect Addressing

Indirect addressing is a mode of addressing data memory where the data memory address in the instruction is not fixed. That is, the register that is to be read or written can be modified by the program. This can be useful for data tables in the data memory. Figure 7-9 shows the operation of indirect addressing. This shows the moving of the value to the data memory address specified by the value of the FSR register.

Example 7-1 shows the use of indirect addressing to clear RAM in a minimum number of instructions. A similar concept could be used to move a defined number of bytes (block) of data to the USART transmit register (TXREG). The starting address of the block of data to be transmitted could easily be modified by the program.

FIGURE 7-9: INDIRECT ADDRESSING

7.4.1 INDIRECT ADDRESSING REGISTERS

The PIC17C75X has four registers for indirect addressing. These registers are:

- INDF0 and FSR0
- INDF1 and FSR1

Registers INDF0 and INDF1 are not physically implemented. Reading or writing to these registers activates indirect addressing, with the value in the corresponding FSR register being the address of the data. The FSR is an 8-bit register and allows addressing anywhere in the 256-byte data memory address range. For banked memory, the bank of memory accessed is specified by the value in the BSR.

If file INDF0 (or INDF1) itself is read indirectly via an FSR, all '0's are read (Zero bit is set). Similarly, if INDF0 (or INDF1) is written to indirectly, the operation will be equivalent to a NOP, and the status bits are not affected.

7.4.2 INDIRECT ADDRESSING OPERATION

The indirect addressing capability has been enhanced over that of the PIC16CXX family. There are two control bits associated with each FSR register. These two bits configure the FSR register to:

- Auto-decrement the value (address) in the FSR after an indirect access
- Auto-increment the value (address) in the FSR after an indirect access
- No change to the value (address) in the FSR after an indirect access

These control bits are located in the ALUSTA register. The FSR1 register is controlled by the FS3:FS2 bits and FSR0 is controlled by the FS1:FS0 bits.

When using the auto-increment or auto-decrement features, the effect on the FSR is not reflected in the ALUSTA register. For example, if the indirect address causes the FSR to equal '0', the Z bit will not be set.

If the FSR register contains a value of 0h, an indirect read will read 0h (Zero bit is set) while an indirect write will be equivalent to a NOP (status bits are not affected).

Indirect addressing allows single cycle data transfers within the entire data space. This is possible with the use of the MOVWF and MOVF instructions, where either 'p' or 'f' is specified as INDF0 (or INDF1).

If the source or destination of the indirect address is in banked memory, the location accessed will be determined by the value in the BSR.

A simple program to clear RAM from 20h - FFh is shown in Example 7-1.

EXAMPLE 7-1: INDIRECT ADDRESSING

```

MOVLW 0x20      ;
MOVWF FSR0      ; FSR0 = 20h
BCF ALUSTA, FS1 ; Increment FSR
BSF ALUSTA, FS0 ; after access
BCF ALUSTA, C   ; C = 0
MOVLW END_RAM + 1 ;
LP CLRF INDF0    ; Addr(FSR) = 0
CPFSEQ FSR0     ; FSR0 = END_RAM+1?
GOTO LP        ; NO, clear next
:              ; YES, All RAM is
:              ; cleared
    
```

7.5 Table Pointer (TBLPTRL and TBLPTRH)

File registers TBLPTRL and TBLPTRH form a 16-bit pointer to address the 64K program memory space. The table pointer is used by instructions TABLWT and TABLRD.

The TABLRD and the TABLWT instructions allow transfer of data between program and data space. The table pointer serves as the 16-bit address of the data word within the program memory. For a more complete description of these registers and the operation of Table Reads and Table Writes, see Section 8.0.

7.6 Table Latch (TBLATH, TBLATL)

The table latch (TBLAT) is a 16-bit register, with TBLATH and TBLATL referring to the high and low bytes of the register. It is not mapped into data or program memory. The table latch is used as a temporary holding latch during data transfer between program and data memory (see TABLRD, TABLWT, TLRD and TLWT instruction descriptions). For a more complete description of these registers and the operation of Table Reads and Table Writes, see Section 8.0.

7.7 Program Counter Module

The Program Counter (PC) is a 16-bit register. PCL, the low byte of the PC, is mapped in the data memory. PCL is readable and writable just as is any other register. PCH is the high byte of the PC and is not directly addressable. Since PCH is not mapped in data or program memory, an 8-bit register PCLATH (PC high latch) is used as a holding latch for the high byte of the PC. PCLATH is mapped into data memory. The user can read or write PCH through PCLATH.

The 16-bit wide PC is incremented after each instruction fetch during Q1 unless:

- Modified by a GOTO, CALL, LCALL, RETURN, RETLW, or RETFIE instruction
- Modified by an interrupt response
- Due to destination write to PCL by an instruction

“Skips” are equivalent to a forced NOP cycle at the skipped address.

Figure 7-10 and Figure 7-11 show the operation of the program counter for various situations.

FIGURE 7-10: PROGRAM COUNTER OPERATION

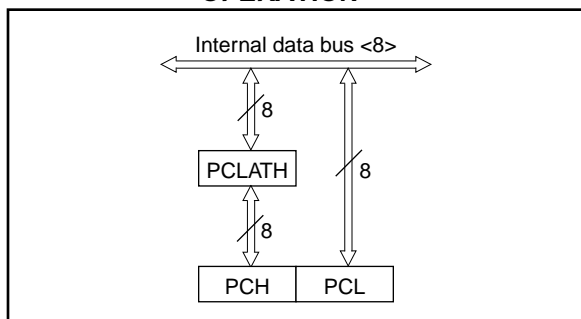

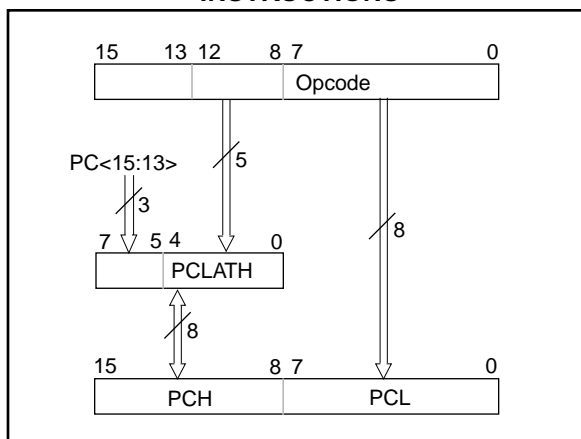

FIGURE 7-11: PROGRAM COUNTER USING THE CALL AND GOTO INSTRUCTIONS

Using Figure 7-10, the operations of the PC and PCLATH for different instructions are as follows:

- LCALL instructions:**
An 8-bit destination address is provided in the instruction (opcode). PCLATH is unchanged.
PCLATH → PCH
Opcode<7:0> → PCL
- Read instructions on PCL:**
Any instruction that reads PCL.
PCL → data bus → ALU or destination
PCH → PCLATH
- Write instructions on PCL:**
Any instruction that writes to PCL.
8-bit data → data bus → PCL
PCLATH → PCH
- Read-Modify-Write instructions on PCL:**
Any instruction that does a read-write-modify operation on PCL, such as ADDWF PCL.
Read: PCL → data bus → ALU
Write: 8-bit result → data bus → PCL
PCLATH → PCH
- RETURN instruction:**
Stack<MRU> → PC<15:0>

Using Figure 7-11, the operation of the PC and PCLATH for GOTO and CALL instructions is as follows:

CALL, GOTO instructions:

A 13-bit destination address is provided in the instruction (opcode).

Opcode<12:0> → PC<12:0>

PC<15:13> → PCLATH<7:5>

Opcode<12:8> → PCLATH<4:0>

The read-modify-write only affects the PCL with the result. PCH is loaded with the value in the PCLATH. For example, ADDWF PCL will result in a jump within the current page. If PC = 03F0h, WREG = 30h and PCLATH = 03h before instruction, PC = 0320h after the instruction. To accomplish a true 16-bit computed jump, the user needs to compute the 16-bit destination address, write the high byte to PCLATH and then write the low value to PCL.

The following PC related operations do not change PCLATH:

- LCALL, RETLW, and RETFIE instructions.
- Interrupt vector is forced onto the PC.
- Read-modify-write instructions on PCL (e.g. BSF PCL).

7.8 Bank Select Register (BSR)

The BSR is used to switch between banks in the data memory area (Figure 7-12). In the PIC17C752, and PIC17C756 devices, the entire byte is implemented. The lower nibble is used to select the peripheral register bank. The upper nibble is used to select the general purpose memory bank.

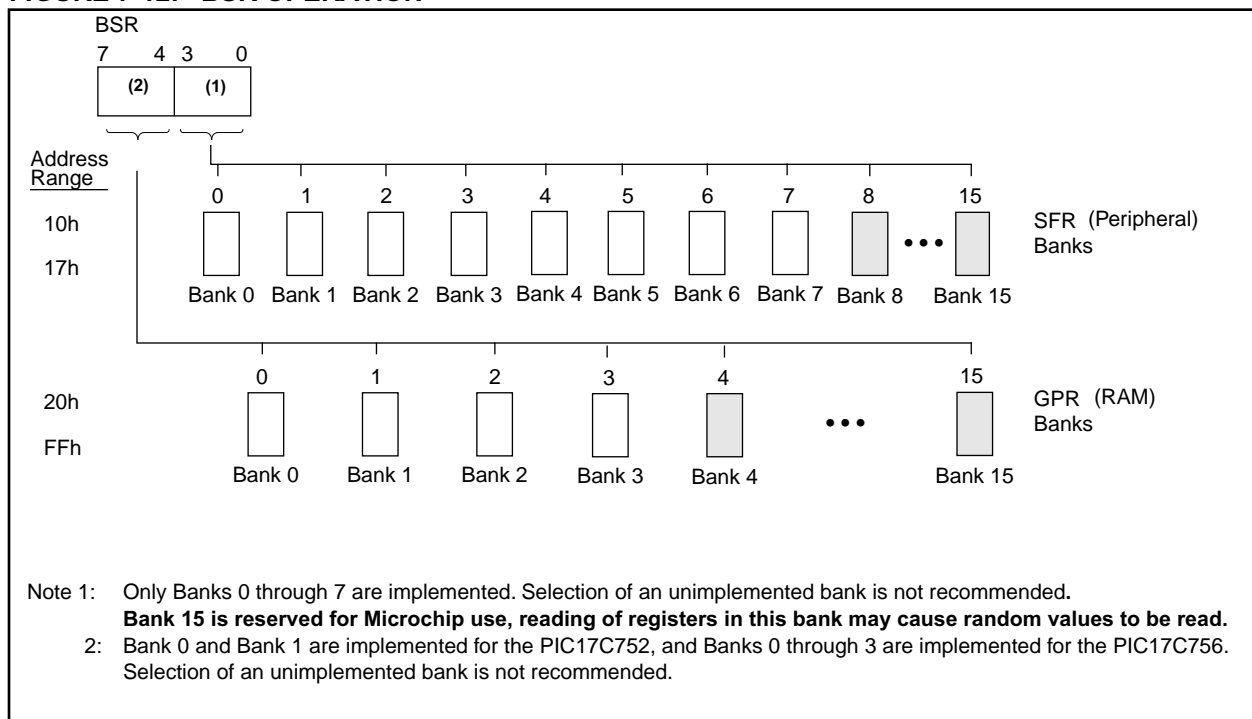

All the Special Function Registers (SFRs) are mapped into the data memory space. In order to accommodate the large number of registers, a banking scheme has been used. A segment of the SFRs, from address 10h to address 17h, is banked. The lower nibble of the bank select register (BSR) selects the currently active "peripheral bank." Effort has been made to group the peripheral registers of related functionality in one bank. However, it will still be necessary to switch from bank to bank in order to address all peripherals related to a single task. To assist this, a `MOVLB` bank instruction has been included in the instruction set.

The need for a large general purpose memory space dictated a general purpose RAM banking scheme. The upper nibble of the BSR selects the currently active general purpose RAM bank. To assist this, a `MOVLB` bank instruction has been provided in the instruction set.

If the currently selected bank is not implemented (such as Bank 13), any read will read all '0's. Any write is completed to the bit bucket and the ALU status bits will be set/cleared as appropriate.

Note: Registers in Bank 15 in the Special Function Register area, are reserved for Microchip use. Reading of registers in this bank may cause random values to be read.

FIGURE 7-12: BSR OPERATION

PIC17C75X

NOTES:

8.0 TABLE READS AND TABLE WRITES

The PIC17C75X has four instructions that allow the processor to move data from the data memory space to the program memory space, and vice versa. Since the program memory space is 16-bits wide and the data memory space is 8-bits wide, two operations are required to move 16-bit values to/from the data memory.

The `TLWT t,f` and `TABLWT t,i,f` instructions are used to write data from the data memory space to the program memory space. The `TLRD t,f` and `TABLRD t,i,f` instructions are used to write data from the program memory space to the data memory space.

The program memory can be internal or external. For the program memory access to be external, the device needs to be operating in extended microcontroller or microprocessor mode.

Figure 8-1 through Figure 8-4 show the operation of these four instructions.

FIGURE 8-1: TLWT INSTRUCTION OPERATION

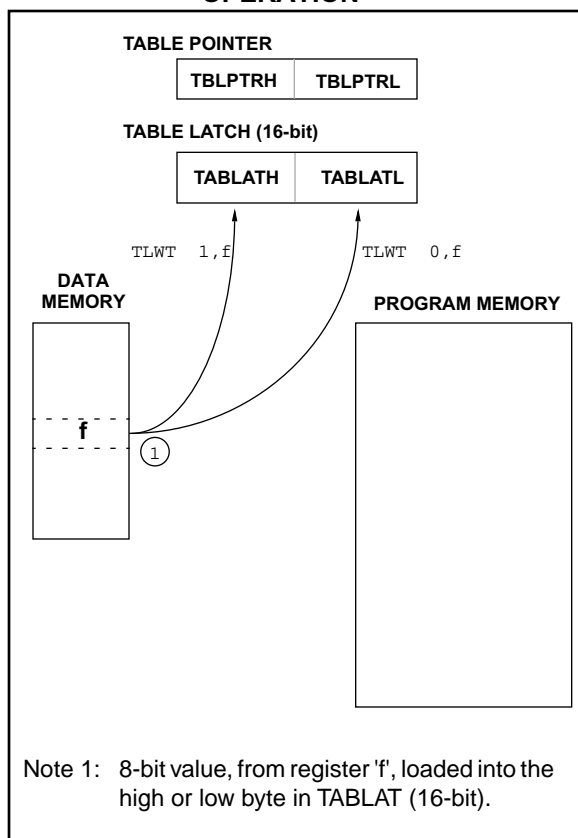

FIGURE 8-2: TABLWT INSTRUCTION OPERATION

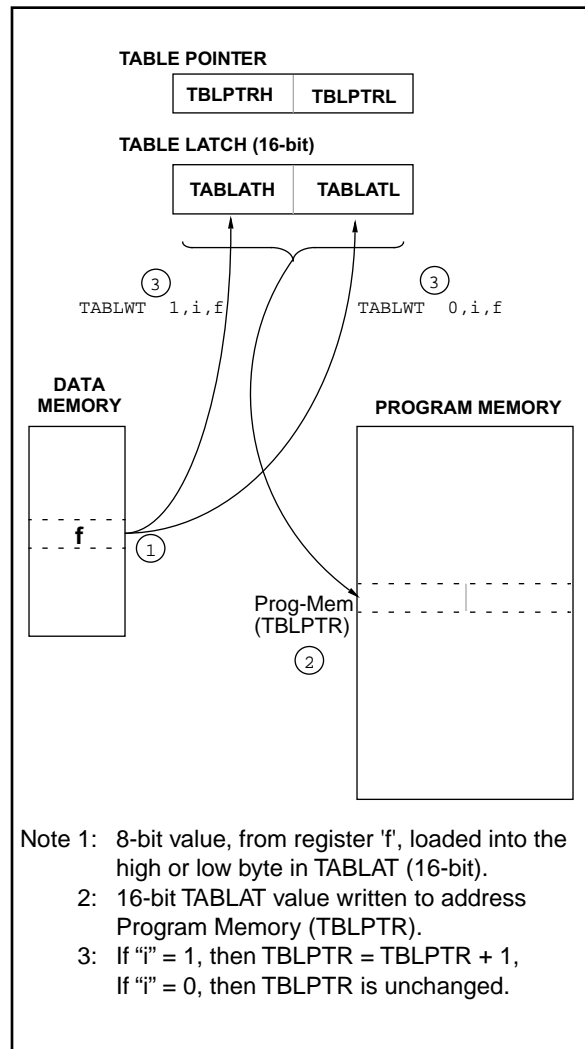

FIGURE 8-3: TLRD INSTRUCTION OPERATION

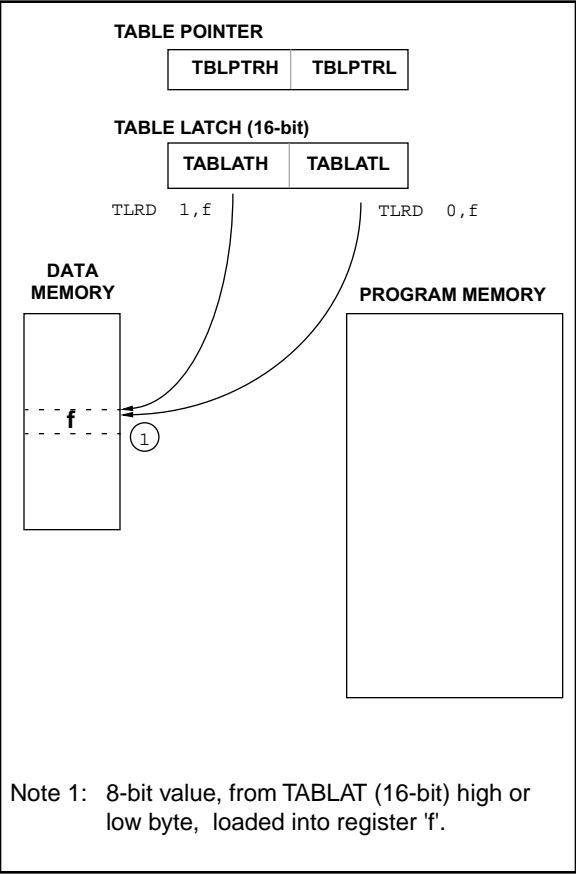

FIGURE 8-4: TABLRD INSTRUCTION OPERATION

8.1 Table Writes to Internal Memory

A table write operation to internal memory causes a long write operation. The long write is necessary for programming the internal EPROM. Instruction execution is halted while in a long write cycle. The long write will be terminated by any enabled interrupt. To ensure that the EPROM location has been well programmed, a minimum programming time is required (see specification #D114). Having only one interrupt enabled to terminate the long write ensures that no unintentional interrupts will prematurely terminate the long write.

The sequence of events for programming an internal program memory location should be:

1. Disable all interrupt sources, except the source to terminate EPROM program write.
2. Raise $\overline{\text{MCLR}}$ /VPP pin to the programming voltage.
3. Clear the WDT.
4. Do the table write. The interrupt will terminate the long write.
5. Verify the memory location (table read).

Note 1: Programming requirements must be met. See timing specification in electrical specifications for the desired device. Violating these specifications (including temperature) may result in EPROM locations that are not fully programmed and may lose their state over time.

Note 2: If the VPP requirement is not met, the table write is a 2 cycle write and the program memory is unchanged.

8.1.1 TERMINATING LONG WRITES

An interrupt source or reset are the only events that terminate a long write operation. Terminating the long write from an interrupt source requires that the interrupt enable and flag bits are set. The GLINTD bit only enables the vectoring to the interrupt address.

If the T0CKI, RA0/INT, or TMR0 interrupt source is used to terminate the long write; the interrupt flag, of the highest priority enabled interrupt, will terminate the long write and automatically be cleared.

Note 1: If an interrupt is pending, the TABLWRT is aborted (an NOP is executed). The highest priority pending interrupt, from the T0CKI, RA0/INT, or TMR0 sources that is enabled, has its flag cleared.

Note 2: If the interrupt is not being used for the program write timing, the interrupt should be disabled. This will ensure that the interrupt is not lost, nor will it terminate the long write prematurely.

If a peripheral interrupt source is used to terminate the long write, the interrupt enable and flag bits must be set. The interrupt flag will not be automatically cleared upon the vectoring to the interrupt vector address.

The GLINTD bit determines whether the program will branch to the interrupt vector when the long write is terminated. If GLINTD is clear, the program will vector, if GLINTD is set, the program will not vector to the interrupt address.

TABLE 8-1: INTERRUPT - TABLE WRITE INTERACTION

Interrupt Source	GLINTD	Enable Bit	Flag Bit	Action
RA0/INT, TMR0, T0CKI	0	1	1	Terminate long table write (to internal program memory), branch to interrupt vector (branch clears flag bit).
	0	1	0	None
	1	0	x	None
	1	1	1	Terminate table write, do not branch to interrupt vector (flag is automatically cleared).
Peripheral	0	1	1	Terminate table write, branch to interrupt vector.
	0	1	0	None
	1	0	x	None
	1	1	1	Terminate table write, do not branch to interrupt vector (flag remains set).

8.2 Table Writes to External Memory

Table writes to external memory are always two-cycle instructions. The second cycle writes the data to the external memory location. The sequence of events for an external memory write are the same for an internal write.

Note: If an interrupt is pending or occurs during the TABLWT, the two cycle table write completes. The RA0/INT, TMR0, or T0CKI interrupt flag is automatically cleared or the pending peripheral interrupt is acknowledged.

8.2.2 TABLE WRITE CODE

The “i” operand of the TABLWT instruction can specify that the value in the 16-bit TBLPTR register is automatically incremented (for the next write). In Example 8-1, the TBLPTR register is not automatically incremented.

EXAMPLE 8-1: TABLE WRITE

```
CLRWDT           ; Clear WDT
MOVLW  HIGH (TBL_ADDR) ; Load the Table
MOVWF  TBLPTRH     ; address
MOVLW  LOW  (TBL_ADDR) ;
MOVWF  TBLPTRL     ;
MOVLW  HIGH (DATA)   ; Load HI byte
TLWT   1, WREG       ; in TABLATH
MOVLW  LOW  (DATA)   ; Load LO byte
TABLWT 0,0,WREG       ; in TABLATH
                        ; and write to
                        ; program memory
                        ; (Ext. SRAM)
```

FIGURE 8-5: TABLWT WRITE TIMING (EXTERNAL MEMORY)

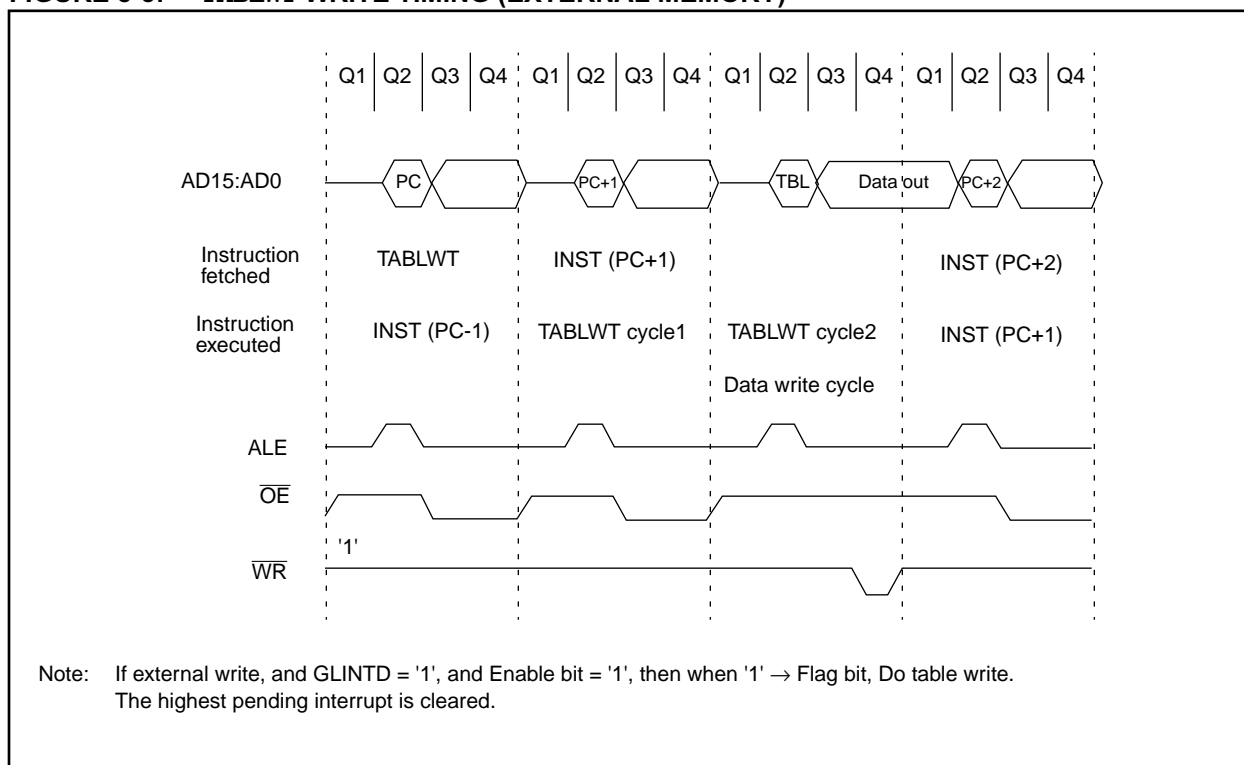

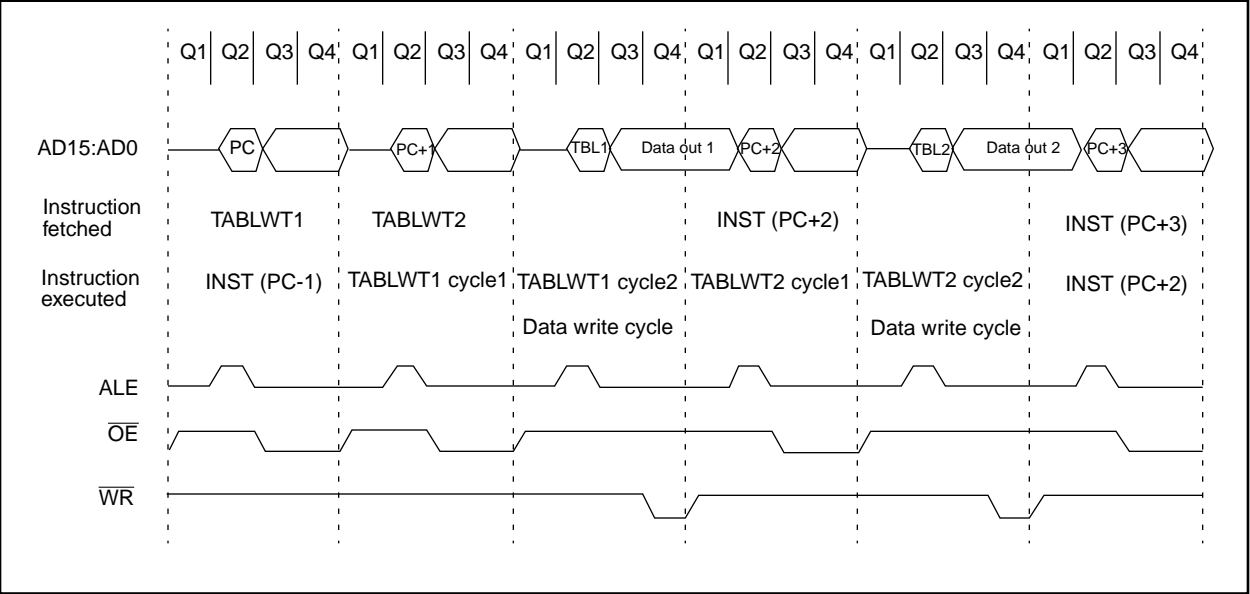

FIGURE 8-6: CONSECUTIVE TABLWLT WRITE TIMING (EXTERNAL MEMORY)

8.3 Table Reads

The table read allows the program memory to be read. This allows constants to be stored in the program memory space, and retrieved into data memory when needed. Example 8-2 reads the 16-bit value at program memory address TBLPTR. After the dummy byte has been read from the TABLATH, the TABLATH is loaded with the 16-bit data from program memory address TBLPTR + 1. The first read loads the data into the latch, and can be considered a dummy read (unknown data loaded into 'f'). INDF0 should be configured for either auto-increment or auto-decrement.

EXAMPLE 8-2: TABLE READ

```
MOVLW    HIGH (TBL_ADDR) ; Load the Table
MOVWF    TBLPTRH          ; address
MOVLW    LOW (TBL_ADDR)  ;
MOVWF    TBLPTRL          ;
TABLRD   0,0,DUMMY        ; Dummy read,
                          ; Updates TABLATH
TLRD     1, INDF0          ; Read HI byte
                          ; of TABLATH
TABLRD   0,1,INDF0        ; Read LO byte
                          ; of TABLATH and
                          ; Update TABLATH
```

FIGURE 8-7: TABLRD TIMING

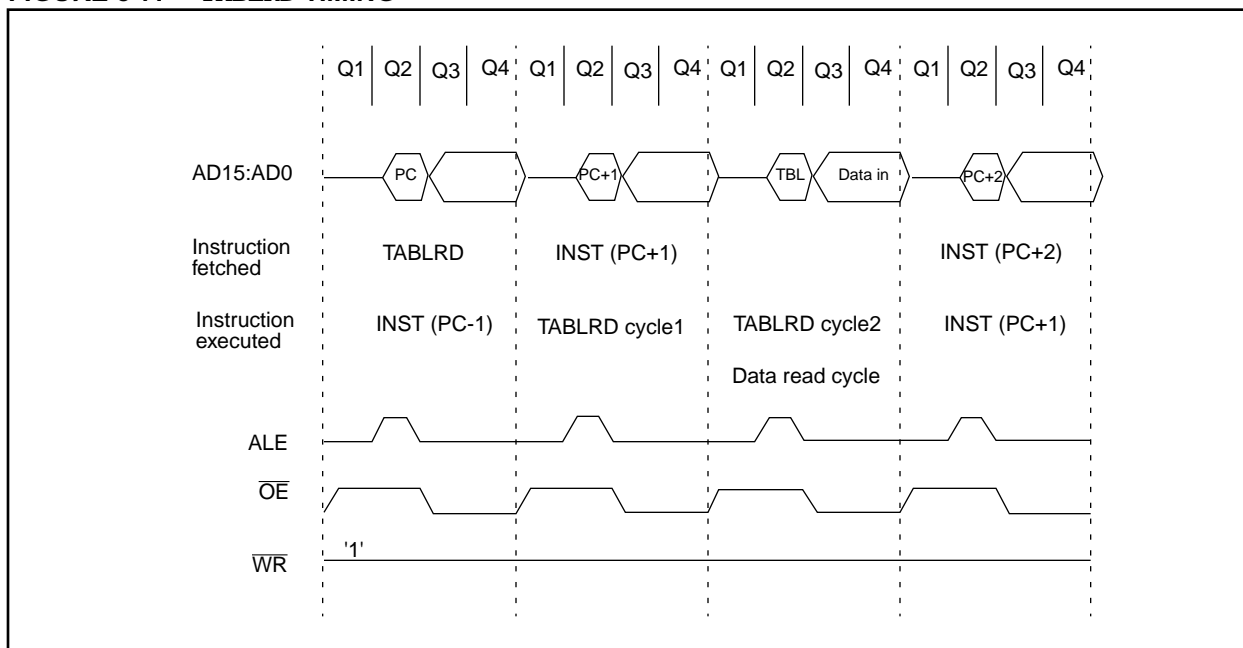

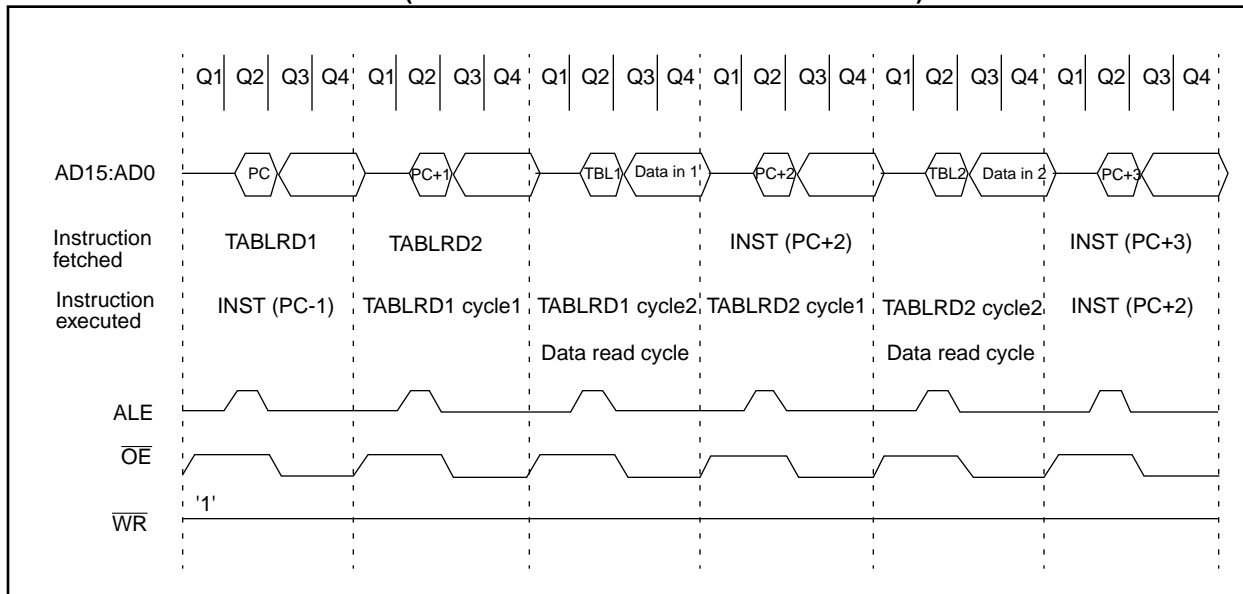

FIGURE 8-8: TABLRD TIMING (CONSECUTIVE TABLRD INSTRUCTIONS)

9.0 HARDWARE MULTIPLIER

All PIC17C75X devices have an 8 x 8 hardware multiplier included in the ALU of the device. By making the multiply a hardware operation, it completes in a single instruction cycle. This is an unsigned multiply that gives a 16-bit result. The result is stored into the 16-bit PRODUct register (PRODH:PRODL). The multiplier does not affect any flags in the ALUSTA register.

Making the 8 x 8 multiplier execute in a single cycle gives the following advantages:

- Higher computational throughput
- Reduces code size requirements for multiply algorithms

The performance increase allows the device to be used in applications previously reserved for Digital Signal Processors.

Table 9-1 shows a performance comparison between PIC17CXXX devices using the single cycle hardware multiply, and performing the same function without the hardware multiply.

Example 9-1 shows the sequence to do an 8 x 8 unsigned multiply. Only one instruction is required when one argument of the multiply is already loaded in the WREG register.

Example 9-2 shows the sequence to do an 8 x 8 signed multiply. To account for the sign bits of the arguments, each argument's most significant bit (MSb) is tested and the appropriate subtractions are done.

EXAMPLE 9-1: 8 x 8 UNSIGNED MULTIPLY ROUTINE

```
MOVFP    ARG1, WREG ;
MULWF    ARG2       ; ARG1 * ARG2 ->
                        ; PRODH:PRODL
```

EXAMPLE 9-2: 8 x 8 SIGNED MULTIPLY ROUTINE

```

NOTES:

10.0 I/O PORTS

PIC17C75X devices have seven I/O ports, PORTA through PORTG. PORTB through PORTG have a corresponding Data Direction Register (DDR), which is used to configure the port pins as inputs or outputs. These seven ports are made up of 50 I/O pins. Some of these ports pins are multiplexed with alternate functions.

PORTC, PORTD, and PORTE are multiplexed with the system bus. These pins are configured as the system bus when the device's configuration bits are selected to Microprocessor or Extended Microcontroller modes. In the two other microcontroller modes, these pins are general purpose I/O.

PORTA, PORTB, PORTE<3>, PORTF and PORTG are multiplexed with the peripheral features of the device. These peripheral features are:

- Timer modules
- Capture modules
- PWM modules
- USART/SCI modules
- SSP Module
- A/D Module
- External Interrupt pin

When some of these peripheral modules are turned on, the port pin will automatically configure to the alternate function. The modules that do this are:

- PWM module
- SSP module
- USART/SCI module

When a pin is automatically configured as an output by a peripheral module, the pins data direction (DDR) bit is unknown. After disabling the peripheral module, the user should re-initialize the DDR bit to the desired configuration.

The other peripheral modules (which require an input) must have their data direction bit configured appropriately.

Note: A pin that is a peripheral input, can be configured as an output (DDR<x> is cleared). The peripheral events will be determined by the action output on the port pin.

10.1 PORTA Register

PORTA is a 6-bit wide latch. PORTA does not have a corresponding Data Direction Register (DDR).

Reading PORTA reads the status of the pins.

The RA1 pin is multiplexed with TMR0 clock input, RA2 and RA3 are multiplexed with the SSP functions, and RA4 and RA5 are multiplexed with the USART1 functions. The control of RA2, RA3, RA4 and RA5 as outputs are automatically configured by the their multiplexed peripheral module.

10.1.1 USING RA2, RA3 AS OUTPUTS

The RA2 and RA3 pins are open drain outputs. To use the RA2 and/or the RA3 pin(s) as output(s), simply write to the PORTA register the desired value. A '0' will cause the pin to drive low, while a '1' will cause the pin to float (hi-impedance). An external pull-up resistor should be used to pull the pin high. Writes to the RA2 and RA3 pins will not affect the other PORTA pins.

Note: When using the RA2 or RA3 pin(s) as output(s), read-modify-write instructions (such as BCF, BSF, BTG) on PORTA are not recommended. Such operations read the port pins, do the desired operation, and then write this value to the data latch. This may inadvertently cause the RA2 or RA3 pins to switch from input to output (or vice-versa). To avoid this possibility use a shadow register for PORTA. Do the bit operations on this shadow register and then move it to PORTA.

Legend: x = unknown, u = unchanged, - = unimplemented reads as '0'. Shaded cells are not used by PORTA.

Note 1: Other (non power-up) resets include: external reset through MCLR and the Watchdog Timer Reset.

10.2 PORTB and DDRB Registers

PORTB is an 8-bit wide bi-directional port. The corresponding data direction register is DDRB. A '1' in DDRB configures the corresponding port pin as an input. A '0' in the DDRB register configures the corresponding port pin as an output. Reading PORTB reads the status of the pins, whereas writing to it will write to the port latch.

Each of the PORTB pins has a weak internal pull-up. A single control bit can turn on all the pull-ups. This is done by clearing the $\overline{\text{RBP}}\text{U}$ (PORTA<7>) bit. The weak pull-up is automatically turned off when the port pin is configured as an output. The pull-ups are enabled on any reset.

PORTB also has an interrupt on change feature. Only pins configured as inputs can cause this interrupt to occur (i.e. any RB7:RB0 pin configured as an output is excluded from the interrupt on change comparison). The input pins (of RB7:RB0) are compared with the value in the PORTB data latch. The "mismatch" outputs of RB7:RB0 are OR'ed together to set the PORTB Interrupt Flag bit, RBIF (PIR1<7>).

This interrupt can wake the device from SLEEP. The user, in the interrupt service routine, can clear the interrupt by:

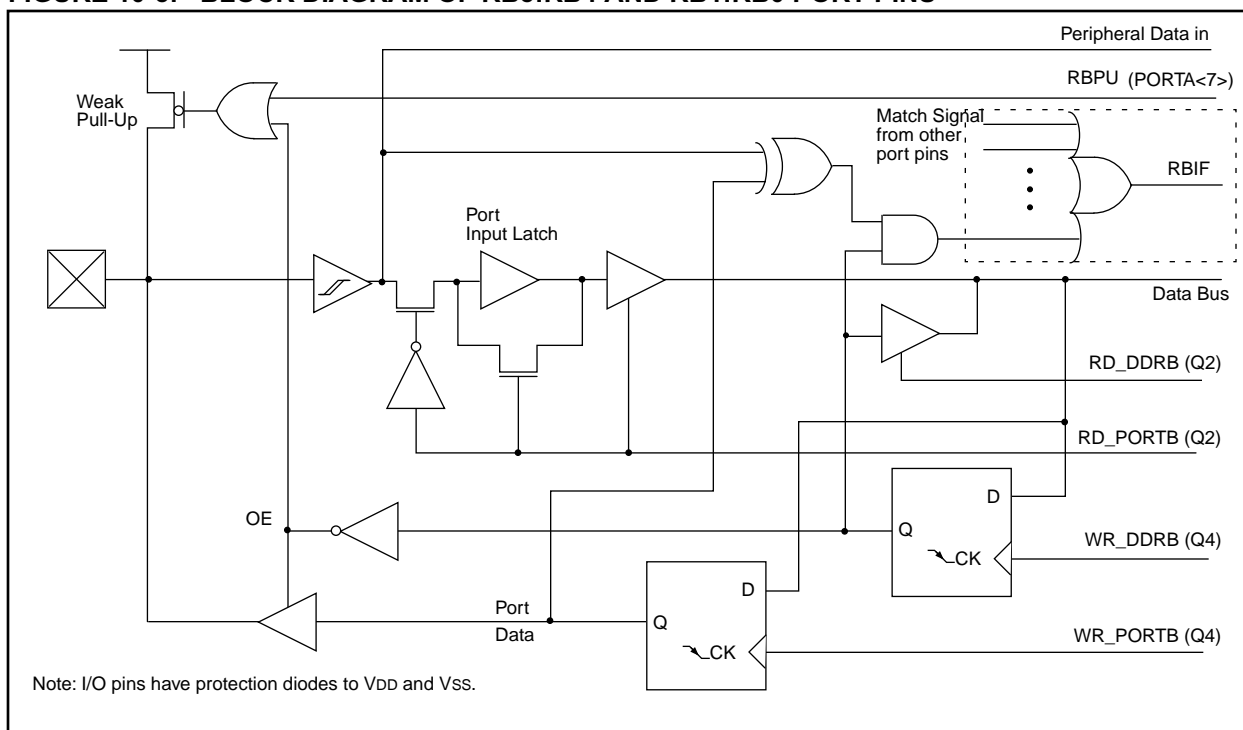

- Read-Write PORTB (such as; `MOVWF PORTB, PORTB`). This will end mismatch condition.
- Then, clear the RBIF bit.

A mismatch condition will continue to set the RBIF bit. Reading then writing PORTB will end the mismatch condition, and allow the RBIF bit to be cleared.

This interrupt on mismatch feature, together with software configurable pull-ups on this port, allows easy interface to a keypad and make it possible for wake-up on key-depression. For an example, refer to Application Note AN552, "Implementing Wake-up on Key-stroke."

The interrupt on change feature is recommended for wake-up on operations where PORTB is only used for the interrupt on change feature and key depression operations.

FIGURE 10-5: BLOCK DIAGRAM OF RB5:RB4 AND RB1:RB0 PORT PINS

Example 10-2 shows an instruction sequence to initialize PORTB. The Bank Select Register (BSR) must be selected to Bank 0 for the port to be initialized. The following example uses the MOVLB instruction to load the BSR register for bank selection.

EXAMPLE 10-2: INITIALIZING PORTB

```
MOVLB 0      ; Select Bank 0
CLRF  PORTB  ; Initialize PORTB by clearing
              ; output data latches
MOVLW 0xCF   ; Value used to initialize
              ; data direction
MOVWF DDRB   ; Set RB<3:0> as inputs
              ; RB<5:4> as outputs
              ; RB<7:6> as inputs
```

Note 1: Other (non power-up) resets include: external reset through $\overline{\text{MCLR}}$ and the Watchdog Timer Reset.

10.3 PORTC and DDRC Registers

PORTC is an 8-bit bi-directional port. The corresponding data direction register is DDRC. A '1' in DDRC configures the corresponding port pin as an input. A '0' in the DDRC register configures the corresponding port pin as an output. Reading PORTC reads the status of the pins, whereas writing to it will write to the port latch. PORTC is multiplexed with the system bus. When operating as the system bus, PORTC is the low order byte of the address/data bus (AD7:AD0). The timing for the system bus is shown in the Electrical Characteristics section.

Note: This port is configured as the system bus when the device's configuration bits are selected to Microprocessor or Extended Microcontroller modes. In the two other microcontroller modes, this port is a general purpose I/O.

Example 10-3 shows an instruction sequence to initialize PORTC. The Bank Select Register (BSR) must be selected to Bank 1 for the port to be initialized. The following example uses the MOVLB instruction to load the BSR register for bank selection.

EXAMPLE 10-3: INITIALIZING PORTC

```
MOVLB 1      ; Select Bank 1
CLRF  PORTC  ; Initialize PORTC data
              ; latches before setting
              ; the data direction register
MOVLW 0xCF   ; Value used to initialize
              ; data direction
MOVWF DDRC   ; Set RC<3:0> as inputs
              ; RC<5:4> as outputs
              ; RC<7:6> as inputs
```

Legend: x = unknown, u = unchanged.

Note 1: Other (non power-up) resets include: external reset through $\overline{\text{MCLR}}$ and the Watchdog Timer Reset.

10.4 PORTD and DDRD Registers

PORTD is an 8-bit bi-directional port. The corresponding data direction register is DDRD. A '1' in DDRD configures the corresponding port pin as an input. A '0' in the DDRD register configures the corresponding port pin as an output. Reading PORTD reads the status of the pins, whereas writing to it will write to the port latch. PORTD is multiplexed with the system bus. When operating as the system bus, PORTD is the high order byte of the address/data bus (AD15:AD8). The timing for the system bus is shown in the Electrical Characteristics section.

Note: This port is configured as the system bus when the device's configuration bits are selected to Microprocessor or Extended Microcontroller modes. In the two other microcontroller modes, this port is a general purpose I/O.

Example 10-4 shows an instruction sequence to initialize PORTD. The Bank Select Register (BSR) must be selected to Bank 1 for the port to be initialized. The following example uses the MOVLB instruction to load the BSR register for bank selection.

EXAMPLE 10-4: INITIALIZING PORTD

```
MOVLB 1      ; Select Bank 1
CLRF  PORTD  ; Initialize PORTD data
              ; latches before setting
              ; the data direction register
MOVLW 0xCF   ; Value used to initialize
              ; data direction
MOVWF DDRD   ; Set RD<3:0> as inputs
              ; RD<5:4> as outputs
              ; RD<7:6> as inputs
```

FIGURE 10-10: BLOCK DIAGRAM OF RD7:RD0 PORT PINS (IN I/O PORT MODE)

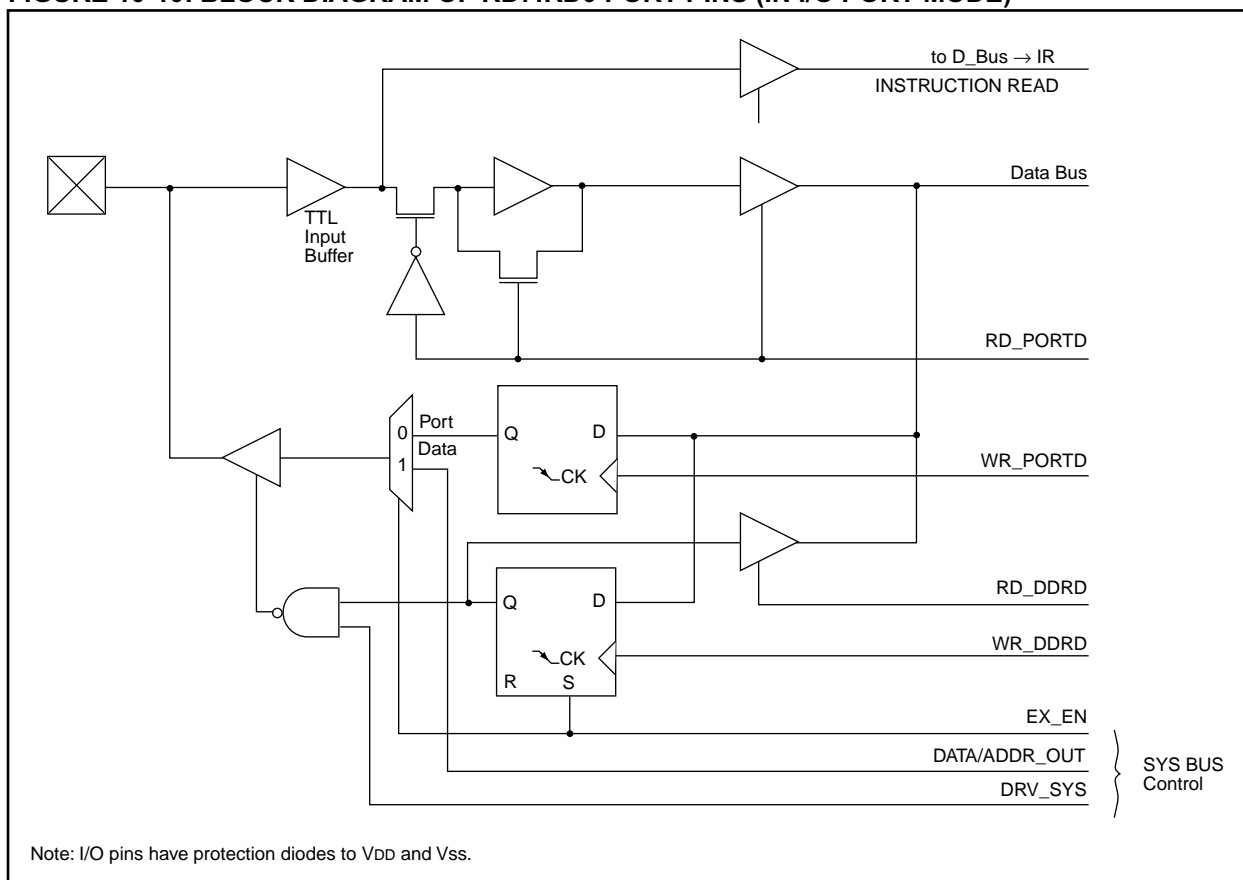

TABLE 10-7: PORTD FUNCTIONS

Legend: x = unknown, u = unchanged.

Note 1: Other (non power-up) resets include: external reset through $\overline{\text{MCLR}}$ and the Watchdog Timer Reset.

10.5 PORTE and DDRE Register

PORTE is a 4-bit bi-directional port. The corresponding data direction register is DDRE. A '1' in DDRE configures the corresponding port pin as an input. A '0' in the DDRE register configures the corresponding port pin as an output. Reading PORTE reads the status of the pins, whereas writing to it will write to the port latch. PORTE is multiplexed with the system bus. When operating as the system bus, PORTE contains the control signals for the address/data bus (AD15:AD0). These control signals are Address Latch Enable (ALE), Output Enable (\overline{OE}), and Write (\overline{WR}). The control signals \overline{OE} and \overline{WR} are active low signals. The timing for the system bus is shown in the Electrical Characteristics section.

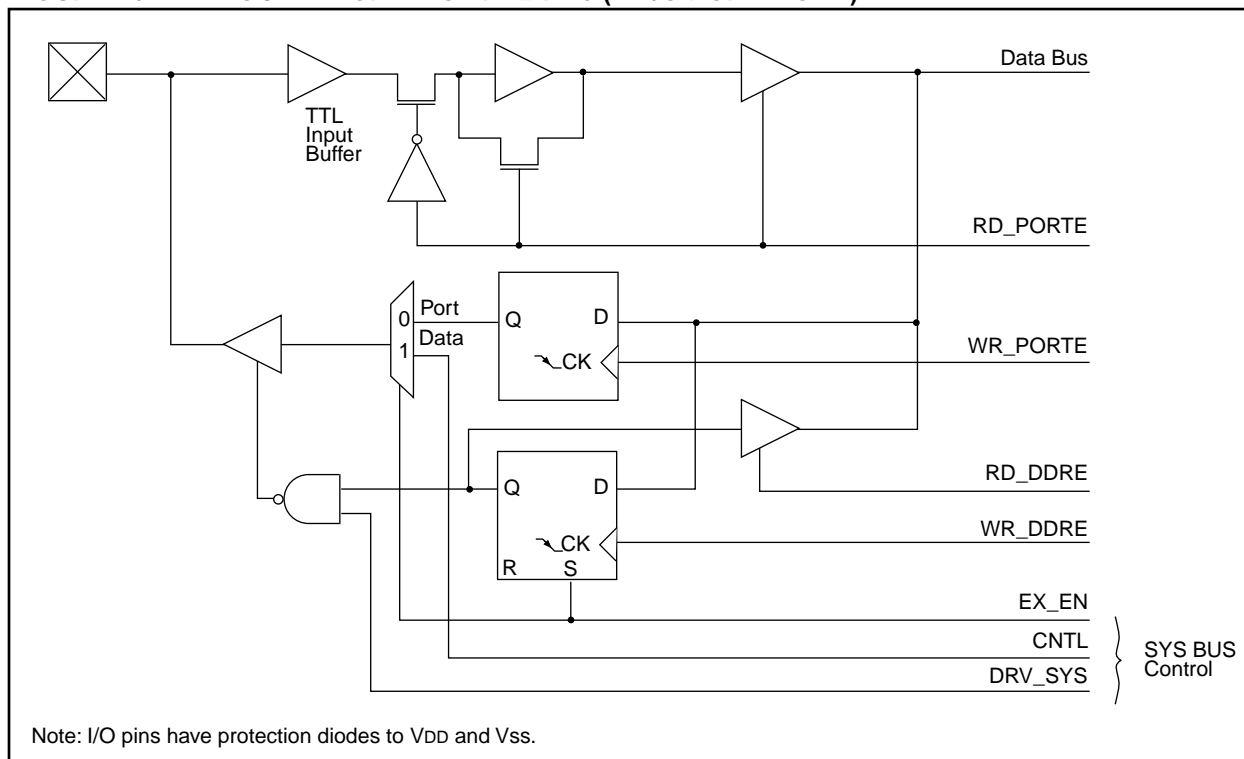

Note: Three pins of this port are configured as the system bus when the device's configuration bits are selected to Microprocessor or Extended Microcontroller modes. The other pin is a general purpose I/O or Capture4 pin. In the two other microcontroller modes, RE2:RE0 are general purpose I/O pins.

Example 10-5 shows an instruction sequence to initialize PORTE. The Bank Select Register (BSR) must be selected to Bank 1 for the port to be initialized. The following example uses the MOVLB instruction to load the BSR register for bank selection.

EXAMPLE 10-5: INITIALIZING PORTE

```
MOVLB 1      ; Select Bank 1
CLRF  PORTE  ; Initialize PORTE data
              ; latches before setting
              ; the data direction
              ; register
MOVLW 0x03   ; Value used to initialize
              ; data direction
MOVWF DDRE   ; Set RE<1:0> as inputs
              ; RE<3:2> as outputs
              ; RE<7:4> are always
              ; read as '0'
```

FIGURE 10-11: BLOCK DIAGRAM OF RE2:RE0 (IN I/O PORT MODE)

10.6 PORTF and DDRF Registers

PORTF is an 8-bit wide bi-directional port. The corresponding data direction register is DDRF. A '1' in DDRF configures the corresponding port pin as an input. A '0' in the DDRF register configures the corresponding port pin as an output. Reading PORTF reads the status of the pins, whereas writing to them will write to the respective port latch.

All eight bits of PORTF are multiplexed with 8 of the 12 channels of the 10-bit A/D converter.

Upon reset the entire Port is automatically configured as analog inputs, and must be configured in software to be a digital I/O.

Example 10-6 shows an instruction sequence to initialize PORTF. The Bank Select Register (BSR) must be selected to Bank 5 for the port to be initialized. The following example uses the MOVLB instruction to load the BSR register for bank selection.

EXAMPLE 10-6: INITIALIZING PORTF

```
MOVLB 5      ; Select Bank 5
MOVLW 0x0E   ; Configure PORTF as
MOVWF ADCON1 ; Digital
CLRWF PORTF  ; Initialize PORTF data
              ; latches before setting
              ; the data direction
              ; register
MOVLW 0x03   ; Value used to initialize
MOVWF DDRF   ; data direction
              ; Set RF<1:0> as inputs
              ; RF<7:2> as outputs
```

Note 1: Other (non power-up) resets include: external reset through MCLR and the Watchdog Timer Reset.

10.8 I/O Programming Considerations

10.8.1 BI-DIRECTIONAL I/O PORTS

Any instruction which writes, operates internally as a read followed by a write operation. For example, the BCF and BSF instructions read the register into the CPU, execute the bit operation, and write the result back to the register. Caution must be used when these instructions are applied to a port with both inputs and outputs defined. For example, a BSF operation on bit5 of PORTB will cause all eight bits of PORTB to be read into the CPU. Then the BSF operation takes place on bit5 and PORTB is written to the output latches. If another bit of PORTB is used as a bi-directional I/O pin (e.g. bit0) and it is defined as an input at this time, the input signal present on the pin itself would be read into the CPU and re-written to the data latch of this particular pin, overwriting the previous content. As long as the pin stays in the input mode, no problem occurs. However, if bit0 is switched into output mode later on, the content of the data latch may now be unknown.

Reading a port reads the values of the port pins. Writing to the port register writes the value to the port latch. When using read-modify-write instructions (BCF, BSF, BTG, etc.) on a port, the value of the port pins is read, the desired operation is performed with this value, and the value is then written to the port latch.

Example 10-8 shows the effect of two sequential read-modify-write instructions on an I/O port.

EXAMPLE 10-8: READ MODIFY WRITE INSTRUCTIONS ON AN I/O PORT

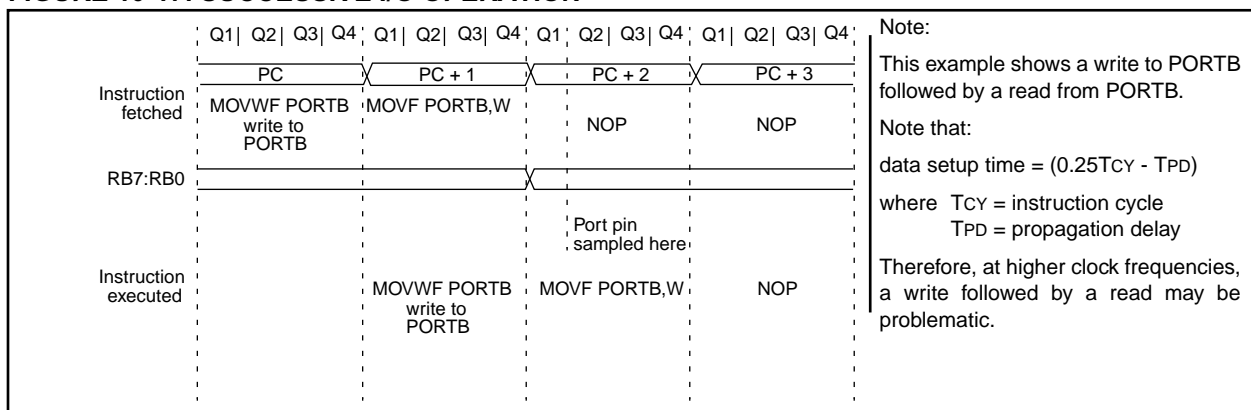

```
; Initial PORT settings: PORTB<7:4> Inputs
;                          PORTB<3:0> Outputs
; PORTB<7:6> have pull-ups and are
; not connected to other circuitry

```

Note: A pin actively outputting a Low or High should not be driven from external devices in order to change the level on this pin (i.e. "wired-or", "wired-and"). The resulting high output currents may damage the device.

10.8.2 SUCCESSIVE OPERATIONS ON I/O PORTS

The actual write to an I/O port happens at the end of an instruction cycle, whereas for reading, the data must be valid at the beginning of the instruction cycle (Figure 10-17). Therefore, care must be exercised if a write followed by a read operation is carried out on the same I/O port. The sequence of instructions should be such to allow the pin voltage to stabilize (load dependent) before executing the instruction that reads the values on that I/O port. Otherwise, the previous state of that pin may be read into the CPU rather than the "new" state. When in doubt, it is better to separate these instructions with a NOP or another instruction not accessing this I/O port.

FIGURE 10-17: SUCCESSIVE I/O OPERATION

PIC17C75X

NOTES:

11.0 OVERVIEW OF TIMER RESOURCES

The PIC17C75X has four timer modules. Each module can generate an interrupt to indicate that an event has occurred. These timers are called:

- Timer0 - 16-bit timer with programmable 8-bit prescaler
- Timer1 - 8-bit timer
- Timer2 - 8-bit timer
- Timer3 - 16-bit timer

For enhanced time-base functionality, four input Captures and three Pulse Width Modulation (PWM) outputs are possible. The PWMs use the Timer1 and Timer2 resources and the input Captures use the Timer3 resource.

11.1 Timer0 Overview

The Timer0 module is a simple 16-bit overflow counter. The clock source can be either the internal system clock ($F_{osc}/4$) or an external clock.

When Timer0 uses an external clock source, it has the flexibility to allow user selection of the incrementing edge, rising or falling.

The Timer0 module also has a programmable prescaler. The PS3:PS0 bits (T0STA<4:1>) determine the prescale value. TMR0 can increment at the following rates: 1:1, 1:2, 1:4, 1:8, 1:16, 1:32, 1:64, 1:128, 1:256.

Synchronization of the external clock occurs after the prescaler. When the prescaler is used, the external clock frequency may be higher than the device's frequency. The maximum external frequency, on the T0CKI pin, is 50 MHz, given the high and low time requirements of the clock.

11.2 Timer1 Overview

The Timer1 module is an 8-bit timer/counter with an 8-bit period register (PR1). When the TMR1 value rolls over from the period match value to 0h, the TMR1IF flag is set, and an interrupt will be generated if enabled. In counter mode, the clock comes from the RB4/TCLK12 pin, which can also be selected to be the clock for the Timer2 module.

TMR1 can be concatenated with TMR2 to form a 16-bit timer. The TMR1 register is the LSB and TMR2 is the MSB. When in the 16-bit timer mode, there is a corresponding 16-bit period register (PR2:PR1). When the TMR2:TMR1 value rolls over from the period match value to 0h, the TMR1IF flag is set, and an interrupt will be generated if enabled.

11.3 Timer2 Overview

The Timer2 module is an 8-bit timer/counter with an 8-bit period register (PR2). When the TMR2 value rolls over from the period match value to 0h, the TMR2IF flag is set, and an interrupt will be generated if enabled. In counter mode, the clock comes from the RB4/TCLK12 pin, which can also provide the clock for the Timer1 module.

TMR2 can be concatenated with TMR1 to form a 16-bit timer. The TMR2 register is the MSB and TMR1 is the LSB. When in the 16-bit timer mode, there is a corresponding 16-bit period register (PR2:PR1). When the TMR2:TMR1 value rolls over from the period match value to 0h, the TMR1IF flag is set, and an interrupt will be generated if enabled.

11.4 Timer3 Overview

The Timer3 module is a 16-bit timer/counter with a 16-bit period register. When the TMR3H:TMR3L value rolls over to 0h, the TMR3IF bit is set and an interrupt will be generated if enabled. In counter mode, the clock comes from the RB5/TCLK3 pin.

When operating in the four capture mode, the period registers become the second (of four) 16-bit capture registers.

11.5 Role of the Timer/Counters

The timer modules are general purpose, but have dedicated resources associated with them. Timer1 and Timer2 are the time-bases for the three Pulse Width Modulation (PWM) outputs, while Timer3 is the time-base for the four input captures.

PIC17C75X

NOTES:

12.0 TIMER0

The Timer0 module consists of a 16-bit timer/counter, TMR0. The high byte is register TMR0H and the low byte is register TMR0L. A software programmable 8-bit prescaler makes Timer0 an effective 24-bit overflow timer. The clock source is software programmable as either the internal instruction clock or an external clock on the RA1/T0CKI pin. The control bits for this module are in register T0STA (Figure 12-1).

FIGURE 12-1: T0STA REGISTER (ADDRESS: 05h, UNBANKED)

U = Unimplemented,
Read as '0'
-n = Value at POR reset

bit 7: **INTEDG:** RA0/INT Pin Interrupt Edge Select bit
This bit selects the edge upon which the interrupt is detected
1 = Rising edge of RA0/INT pin generates interrupt
0 = Falling edge of RA0/INT pin generates interrupt

bit 6: **T0SE:** Timer0 Clock Input Edge Select bit
This bit selects the edge upon which TMR0 will increment
When T0CS = 0 (External Clock)
1 = Rising edge of RA1/T0CKI pin increments TMR0 and/or generates a T0CKIF interrupt
0 = Falling edge of RA1/T0CKI pin increments TMR0 and/or generates a T0CKIF interrupt
When T0CS = 1 (Internal Clock)
Don't care

bit 5: **T0CS:** Timer0 Clock Source Select bit
This bit selects the clock source for TMR0.
1 = Internal instruction clock cycle (Tcy)
0 = External Clock input on the T0CKI pin

bit 4-1: **T0PS3:T0PS0:** Timer0 Prescale Selection bits
These bits select the prescale value for TMR0.

T0PS3:T0PS0	Prescale Value
0000	1:1
0001	1:2
0010	1:4
0011	1:8
0100	1:16
0101	1:32
0110	1:64
0111	1:128
1xxx	1:256

bit 0: **Unimplemented:** Read as '0'

12.1 Timer0 Operation

When the T0CS (T0STA<5>) bit is set, TMR0 increments on the internal clock. When T0CS is clear, TMR0 increments on the external clock (RA1/T0CKI pin). The external clock edge can be selected in software. When the T0SE (T0STA<6>) bit is set, the timer will increment on the rising edge of the RA1/T0CKI pin. When T0SE is clear, the timer will increment on the falling edge of the RA1/T0CKI pin. The prescaler can be programmed to introduce a prescale of 1:1 to 1:256. The timer increments from 0000h to FFFFh and rolls over to 0000h. On overflow, the TMR0 Interrupt Flag bit (T0IF) is set. The TMR0 interrupt can be masked by clearing the corresponding TMR0 Interrupt Enable bit (T0IE). The TMR0 Interrupt Flag bit (T0IF) is automatically cleared when vectoring to the TMR0 interrupt vector.

12.2 Using Timer0 with External Clock

When an external clock input is used for Timer0, it is synchronized with the internal phase clocks. Figure 12-3 shows the synchronization of the external clock. This synchronization is done after the prescaler. The output of the prescaler (PSOUT) is sampled twice in every instruction cycle to detect a rising or a falling edge. The timing requirements for the external clock are detailed in the electrical specification section.

12.2.1 DELAY FROM EXTERNAL CLOCK EDGE

Since the prescaler output is synchronized with the internal clocks, there is a small delay from the time the external clock edge occurs to the time TMR0 is actually incremented. Figure 12-3 shows that this delay is between $3T_{osc}$ and $7T_{osc}$. Thus, for example, measuring the interval between two edges (e.g. period) will be accurate within $\pm 4T_{osc}$ (± 121 ns @ 33 MHz).

FIGURE 12-2: TIMER0 MODULE BLOCK DIAGRAM

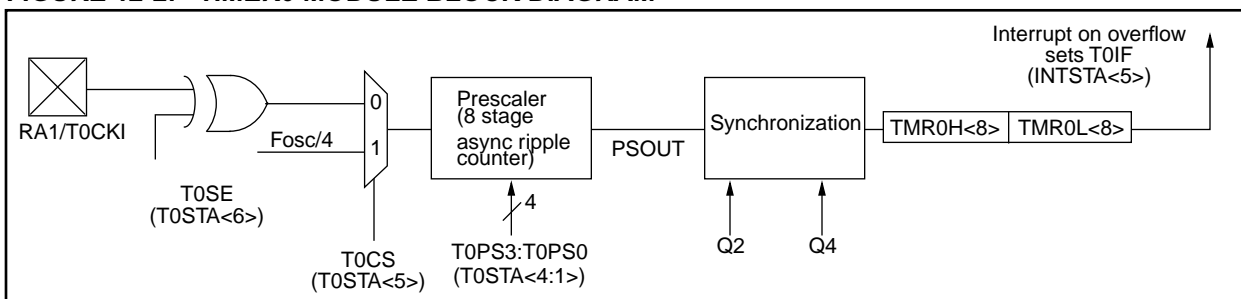

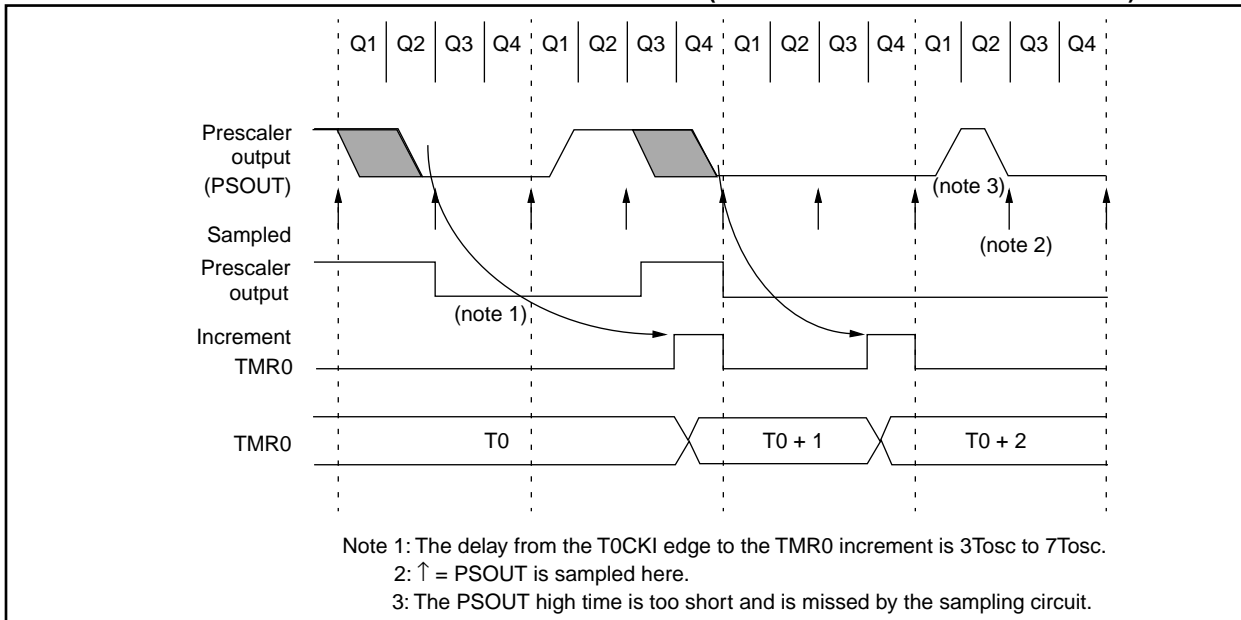

FIGURE 12-3: TMR0 TIMING WITH EXTERNAL CLOCK (INCREMENT ON FALLING EDGE)

12.3 Read/Write Consideration for TMR0

Although TMR0 is a 16-bit timer/counter, only 8-bits at a time can be read or written during a single instruction cycle. Care must be taken during any read or write.

12.3.1 READING 16-BIT VALUE

The problem in reading the entire 16-bit value is that after reading the low (or high) byte, its value may change from FFh to 00h.

Example 12-1 shows a 16-bit read. To ensure a proper read, interrupts must be disabled during this routine.

EXAMPLE 12-1: 16-BIT READ

```
MOVFP  TMR0L, TMPLO ;read low tmr0
MOVFP  TMR0H, TMPHI ;read high tmr0
MOVFP  TMPLO, WREG   ;tmplo -> wreg
CPFSLT TMR0L         ;tmr0l < wreg?
RETURN ;no then return
MOVFP  TMR0L, TMPLO ;read low tmr0
MOVFP  TMR0H, TMPHI ;read high tmr0
RETURN ;return
```

12.3.2 WRITING A 16-BIT VALUE TO TMR0

Since writing to either TMR0L or TMR0H will effectively inhibit increment of that half of the TMR0 in the next cycle (following write), but not inhibit increment of the other half, the user must write to TMR0L first and TMR0H second in two consecutive instructions, as shown in Example 12-2. The interrupt must be disabled. Any write to either TMR0L or TMR0H clears the prescaler.

EXAMPLE 12-2: 16-BIT WRITE

```
BSF    CPUSTA, GLINTD ; Disable interrupts
MOVFP  RAM_L, TMR0L   ;
MOVFP  RAM_H, TMR0H   ;
BCF    CPUSTA, GLINTD ; Done, enable
                        ; interrupts
```

12.4 Prescaler Assignments

Timer0 has an 8-bit prescaler. The prescaler assignment is fully under software control; i.e., it can be changed "on the fly" during program execution. When changing the prescaler assignment, clearing the prescaler is recommended before changing assignment. The value of the prescaler is "unknown," and assigning a value that is less than the present value makes it difficult to take this unknown time into account.

FIGURE 12-4: TMR0 TIMING: WRITE HIGH OR LOW BYTE

Note 1: Other (non power-up) resets include: external reset through MCLR and the Watchdog Timer Reset.

13.0 TIMER1, TIMER2, TIMER3, PWMS AND CAPTURES

The PIC17C75X has a wealth of timers and time-based functions to ease the implementation of control applications. These time-base functions include three PWM outputs and four Capture inputs.

Timer1 and Timer2 are two 8-bit incrementing timers, each with an 8-bit period register (PR1 and PR2 respectively) and separate overflow interrupt flags. Timer1 and Timer2 can operate either as timers (increment on internal Fosc/4 clock) or as counters (increment on falling edge of external clock on pin RB4/TCLK12). They are also software configurable to operate as a single 16-bit timer/counter. These timers are also used as the time-base for the PWM (Pulse Width Modulation) modules.

Timer3 is a 16-bit timer/counter which uses the TMR3H and TMR3L registers. Timer3 also has two additional registers (PR3H/CA1H: PR3L/CA1L) that are configurable as a 16-bit period register or a 16-bit capture register. TMR3 can be software configured to increment from the internal system clock (Fosc/4) or from an external signal on the RB5/TCLK3 pin. Timer3 is the time-base for all of the 16-bit captures.

Six other registers comprise the Capture2, Capture3, and Capture4 registers (CA2H:CA2L, CA3H:CA3L, and CA4H:CA4L).

Figure 13-1, Figure 13-2, and Figure 13-3 are the control registers for the operation of Timer1, Timer2, and Timer3, as well as PWM1, PWM2, PWM3, Capture1, Capture2, Capture3, and Capture4.

Table 13-1 shows the Timer resource requirements for these time-base functions. Each timer is an open resource so that multiple functions may operate with it.

TABLE 13-1: TIME-BASE FUNCTION / RESOURCE REQUIREMENTS

Time-base Function	Timer Resource
PWM1	Timer1
PWM2	Timer1 or Timer2
PWM3	Timer1 or Timer2
Capture1	Timer3
Capture2	Timer3
Capture3	Timer3
Capture4	Timer3

R - 0	R - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0
CA2OVF	CA1OVF	PWM2ON	PWM1ON	CA1/PR3	TMR3ON	TMR2ON	TMR1ON
bit7							bit0

R = Readable bit
W = Writable bit
-n = Value at POR reset

bit 7: **CA2OVF**: Capture2 Overflow Status bit
This bit indicates that the capture value had not been read from the capture register pair (CA2H:CA2L) before the next capture event occurred. The capture register retains the oldest unread capture value (last capture before overflow). Subsequent capture events will not update the capture register with the TMR3 value until the capture register has been read (both bytes).
1 = Overflow occurred on Capture2 register
0 = No overflow occurred on Capture2 register

bit 6: **CA1OVF**: Capture1 Overflow Status bit
This bit indicates that the capture value had not been read from the capture register pair (PR3H/CA1H:PR3L/CA1L) before the next capture event occurred. The capture register retains the oldest unread capture value (last capture before overflow). Subsequent capture events will not update the capture register with the TMR3 value until the capture register has been read (both bytes).
1 = Overflow occurred on Capture1 register
0 = No overflow occurred on Capture1 register

bit 5: **PWM2ON**: PWM2 On bit
1 = PWM2 is enabled (The RB3/PWM2 pin ignores the state of the DDRB<3> bit)
0 = PWM2 is disabled (The RB3/PWM2 pin uses the state of the DDRB<3> bit for data direction)

bit 4: **PWM1ON**: PWM1 On bit
1 = PWM1 is enabled (The RB2/PWM1 pin ignores the state of the DDRB<2> bit)
0 = PWM1 is disabled (The RB2/PWM1 pin uses the state of the DDRB<2> bit for data direction)

bit 3: **CA1/PR3**: CA1/PR3 Register Mode Select bit
1 = Enables Capture1 (PR3H/CA1H:PR3L/CA1L is the Capture1 register. Timer3 runs without a period register)
0 = Enables the Period register (PR3H/CA1H:PR3L/CA1L is the Period register for Timer3)

bit 2: **TMR3ON**: Timer3 On bit
1 = Starts Timer3
0 = Stops Timer3

bit 1: **TMR2ON**: Timer2 On bit
This bit controls the incrementing of the TMR2 register. When TMR2:TMR1 form the 16-bit timer (T16 is set), TMR2ON must be set. This allows the MSB of the timer to increment.
1 = Starts Timer2 (Must be enabled if the T16 bit (TCON1<3>) is set)
0 = Stops Timer2

bit 0: **TMR1ON**: Timer1 On bit
When T16 is set (in 16-bit Timer Mode)
1 = Starts 16-bit TMR2:TMR1
0 = Stops 16-bit TMR2:TMR1

When T16 is clear (in 8-bit Timer Mode)
1 = Starts 8-bit Timer1
0 = Stops 8-bit Timer1

bit 7: **Unimplemented:** Read as '0'

bit 6: **CA4OVF:** Capture4 Overflow Status bit
This bit indicates that the capture value had not been read from the capture register pair (CA4H:CA4L) before the next capture event occurred. The capture register retains the oldest unread capture value (last capture before overflow). Subsequent capture events will not update the capture register with the TMR3 value until the capture register has been read (both bytes).
1 = Overflow occurred on Capture4 registers
0 = No overflow occurred on Capture4 registers

bit 5: **CA3OVF:** Capture3 Overflow Status bit
This bit indicates that the capture value had not been read from the capture register pair (CA3H:CA3L) before the next capture event occurred. The capture register retains the oldest unread capture value (last capture before overflow). Subsequent capture events will not update the capture register with the TMR3 value until the capture register has been read (both bytes).
1 = Overflow occurred on Capture3 registers
0 = No overflow occurred on Capture3 registers

bit 4-3: **CA4ED1:CA4ED0:** Capture4 Mode Select bits
00 = Capture on every falling edge
01 = Capture on every rising edge
10 = Capture on every 4th rising edge
11 = Capture on every 16th rising edge

bit 2-1: **CA3ED1:CA3ED0:** Capture3 Mode Select bits
00 = Capture on every falling edge
01 = Capture on every rising edge
10 = Capture on every 4th rising edge
11 = Capture on every 16th rising edge

bit 0: **PWM3ON:** PWM3 On bit
1 = PWM3 is enabled (The RG5/PWM3 pin ignores the state of the DDRG<5> bit)
0 = PWM3 is disabled (The RG5/PWM3 pin uses the state of the DDRG<5> bit for data direction)

13.1 Timer1 and Timer2

13.1.1 TIMER1, TIMER2 IN 8-BIT MODE

Both Timer1 and Timer2 will operate in 8-bit mode when the T16 bit is clear. These two timers can be independently configured to increment from the internal instruction cycle clock (T_{CY}) or from an external clock source on the RB4/TCLK12 pin. The timer clock source is configured by the TMRxCS bit ($x = 1$ for Timer1 or $= 2$ for Timer2). When TMRxCS is clear, the clock source is internal and increments once every instruction cycle ($F_{osc}/4$). When TMRxCS is set, the clock source is the RB4/TCLK12 pin, and the counters will increment on every falling edge of the RB4/TCLK12 pin.

The timer increments from 00h until it equals the Period register (PRx). It then resets to 00h at the next increment cycle. The timer interrupt flag is set when the timer is reset. TMR1 and TMR2 have individual interrupt flag bits. The TMR1 interrupt flag bit is latched into TMR1IF, and the TMR2 interrupt flag bit is latched into TMR2IF.

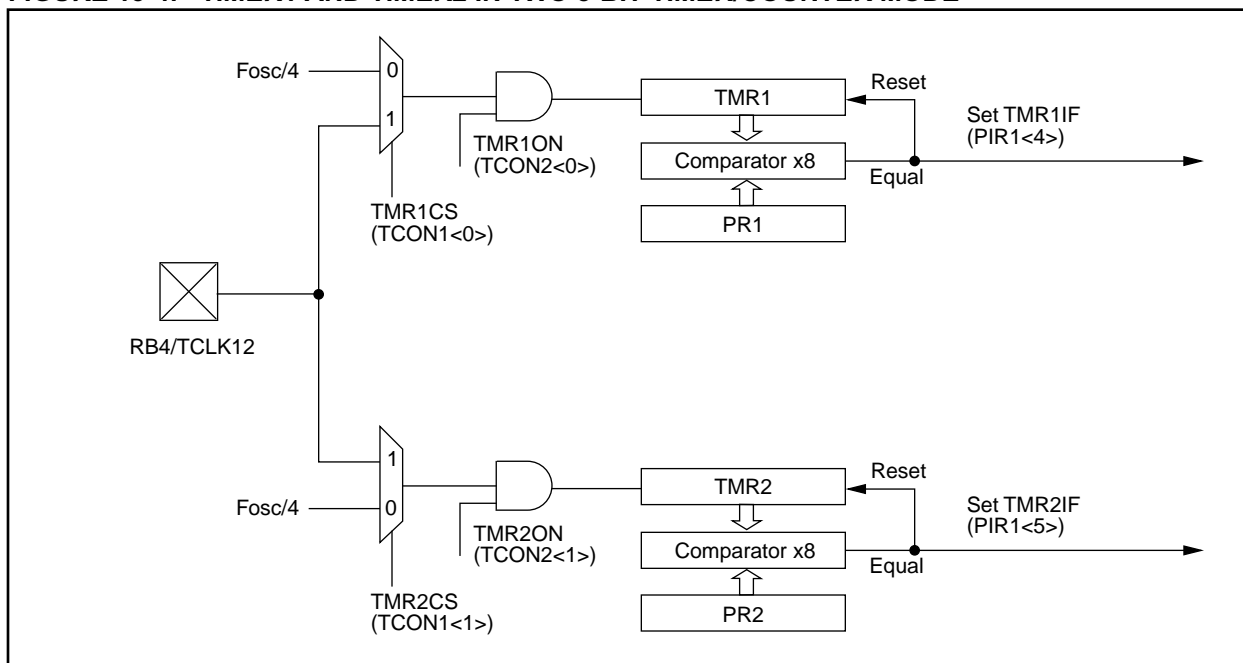

Each timer also has a corresponding interrupt enable bit (TMRxIE). The timer interrupt can be enabled/disabled by setting/clearing this bit. For peripheral interrupts to be enabled, the Peripheral Interrupt Enable bit must be set ($PEIE = '1'$) and global interrupt must be enabled ($GLINTD = '0'$).

The timers can be turned on and off under software control. When the timer on control bit (TMRxON) is set, the timer increments from the clock source. When TMRxON is cleared, the timer is turned off and cannot cause the timer interrupt flag to be set.

13.1.1.1 EXTERNAL CLOCK INPUT FOR TIMER1 AND TIMER2

When TMRxCS is set, the clock source is the RB4/TCLK12 pin, and the counter will increment on every falling edge on the RB4/TCLK12 pin. The TCLK12 input is synchronized with internal phase clocks. This causes a delay from the time a falling edge appears on TCLK12 to the time TMR1 or TMR2 is actually incremented. For the external clock input timing requirements, see the Electrical Specification section.

FIGURE 13-4: TIMER1 AND TIMER2 IN TWO 8-BIT TIMER/COUNTER MODE

13.1.2 TIMER1 AND TIMER2 IN 16-BIT MODE

To select 16-bit mode, set the T16 bit. In this mode TMR2 and TMR1 are concatenated to form a 16-bit timer (TMR2:TMR1). The 16-bit timer increments until it matches the 16-bit period register (PR2:PR1). On the following timer clock, the timer value is reset to 0h, and the TMR1IF bit is set.

When selecting the clock source for the 16-bit timer, the TMR1CS bit controls the entire 16-bit timer and TMR2CS is a "don't care", however ensure that TMR2ON is set (allows TMR2 to increment). When TMR1CS is clear, the timer increments once every instruction cycle ($F_{osc}/4$). When TMR1CS is set, the timer increments on every falling edge of the RB4/TCLK12 pin. For the 16-bit timer to increment, both TMR1ON and TMR2ON bits must be set (Table 13-2).

TABLE 13-2: TURNING ON 16-BIT TIMER

T16	TMR2ON	TMR1ON	Result
1	1	1	16-bit timer (TMR2:TMR1) ON
1	0	1	Only TMR1 increments
1	x	0	16-bit timer OFF
0	1	1	Timers in 8-bit mode

13.1.2.1 EXTERNAL CLOCK INPUT FOR TMR2:TMR1

When TMR1CS is set, the 16-bit TMR2:TMR1 increments on the falling edge of clock input TCLK12. The input on the RB4/TCLK12 pin is sampled and synchronized by the internal phase clocks twice every instruction cycle. This causes a delay from the time a falling edge appears on RB4/TCLK12 to the time TMR2:TMR1 is actually incremented. For the external clock input timing requirements, see the Electrical Specification section.

Legend: x = unknown, u = unchanged, - = unimplemented read as a '0', q - value depends on condition, shaded cells are not used by Timer1 or Timer2.

Note 1: Other (non power-up) resets include: external reset through MCLR and WDT Timer Reset.

13.1.3 USING PULSE WIDTH MODULATION (PWM) OUTPUTS WITH TIMER1 AND TIMER2

Three high speed pulse width modulation (PWM) outputs are provided. The PWM1 output uses Timer1 as its time-base, while PWM2 and PWM3 may independently be software configured to use either Timer1 or Timer2 as the time-base. The PWM outputs are on the RB2/PWM1, RB3/PWM2, and RG5/PWM3 pins.

Each PWM output has a maximum resolution of 10-bits. At 10-bit resolution, the PWM output frequency is 32.2 kHz (@ 32 MHz clock) and at 8-bit resolution the PWM output frequency is 128.9 kHz. The duty cycle of the output can vary from 0% to 100%.

Figure 13-6 shows a simplified block diagram of a PWM module.

The duty cycle registers are double buffered for glitch free operation. Figure 13-7 shows how a glitch could occur if the duty cycle registers were not double buffered.

The user needs to set the PWM1ON bit (TCON2<4>) to enable the PWM1 output. When the PWM1ON bit is set, the RB2/PWM1 pin is configured as PWM1 output and forced as an output irrespective of the data direction bit (DDRB<2>). When the PWM1ON bit is clear, the pin behaves as a port pin and its direction is controlled by its data direction bit (DDRB<2>). Similarly, the PWM2ON (TCON2<5>) bit controls the configuration of the RB3/PWM2 pin and the PWM3ON (TCON3<0>) bit controls the configuration of the RG5/PWM3 pin.

FIGURE 13-6: SIMPLIFIED PWM BLOCK DIAGRAM

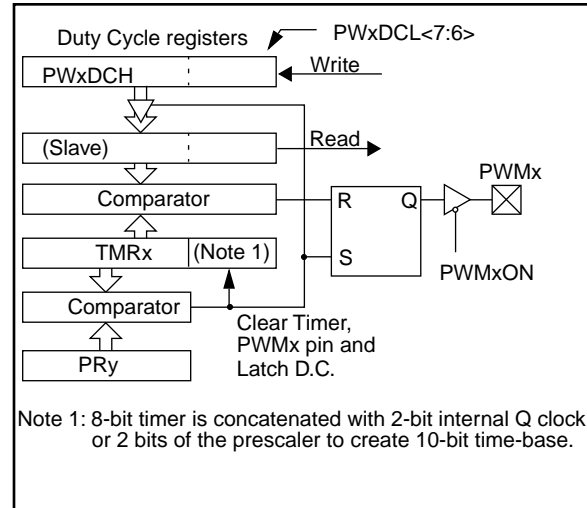

FIGURE 13-7: PWM OUTPUT

13.1.3.1 PWM PERIODS

The period of the PWM1 output is determined by Timer1 and its period register (PR1). The period of the PWM2 and PWM3 outputs can be individually software configured to use either Timer1 or Timer2 as the time-base. For PWM2, when TM2PW2 bit (PW2DCL<5>) is clear, the time-base is determined by TMR1 and PR1, and when TM2PW2 is set, the time-base is determined by Timer2 and PR2. For PWM3, when TM2PW3 bit (PW3DCL<5>) is clear, the time-base is determined by TMR1 and PR1, and when TM2PW3 is set, the time-base is determined by Timer2 and PR2.

Running two different PWM outputs on two different timers allows different PWM periods. Running all PWMs from Timer1 allows the best use of resources by freeing Timer2 to operate as an 8-bit timer. Timer1 and Timer2 can not be used as a 16-bit timer if any PWM is being used.

The PWM periods can be calculated as follows:

$$\text{period of PWM1} = [(PR1) + 1] \times 4T_{OSC}$$

$$\text{period of PWM2} = [(PR1) + 1] \times 4T_{OSC} \quad \text{or} \quad [(PR2) + 1] \times 4T_{OSC}$$

$$\text{period of PWM3} = [(PR1) + 1] \times 4T_{OSC} \quad \text{or} \quad [(PR2) + 1] \times 4T_{OSC}$$

The duty cycle of PWMx is determined by the 10-bit value DCx<9:0>. The upper 8-bits are from register PWxDCH and the lower 2-bits are from PWxDCL<7:6> (PWxDCH:PWxDCL<7:6>). Table 13-4 shows the maximum PWM frequency (F_{PWM}) given the value in the period register.

The number of bits of resolution that the PWM can achieve depends on the operation frequency of the device as well as the PWM frequency (F_{PWM}).

Maximum PWM resolution (bits) for a given PWM frequency:

$$= \frac{\log \left(\frac{F_{OSC}}{F_{PWM}} \right)}{\log (2)} \quad \text{bits}$$

where: F_{PWM} = 1 / period of PWM

The PWMx duty cycle is as follows:

$$\text{PWMx Duty Cycle} = (DCx) \times T_{OSC}$$

where DCx represents the 10-bit value from PWxDCH:PWxDCL.

If DCx = 0, then the duty cycle is zero. If PRx = PWxDCH, then the PWM output will be low for one to four Q-clock (depending on the state of the PWxDCL<7:6> bits). For a Duty Cycle to be 100%, the PWxDCH value must be greater than the PRx value.

The duty cycle registers for both PWM outputs are double buffered. When the user writes to these registers, they are stored in master latches. When TMR1 (or TMR2) overflows and a new PWM period begins, the master latch values are transferred to the slave latches and the PWMx pin is forced high.

Note: For PW1DCH, PW1DCL, PW2DCH, PW2DCL, PW3DCH and PW3DCL registers, a write operation writes to the "master latches" while a read operation reads the "slave latches". As a result, the user may not read back what was just written to the duty cycle registers.

The user should also avoid any "read-modify-write" operations on the duty cycle registers, such as: ADDWF PW1DCH. This may cause duty cycle outputs that are unpredictable.

TABLE 13-4: PWM FREQUENCY vs. RESOLUTION AT 33 MHz

PWM Frequency	Frequency (kHz)				
	32.2	64.5	90.66	128.9	515.6
PRx Value	0xFF	0x7F	0x5A	0x3F	0x0F
High Resolution	10-bit	9-bit	8.5-bit	8-bit	6-bit
Standard Resolution	8-bit	7-bit	6.5-bit	6-bit	4-bit

13.1.3.2 PWM INTERRUPTS

The PWM modules makes use of the TMR1 and/or TMR2 interrupts. A timer interrupt is generated when TMR1 or TMR2 equals its period register and on the following increment is cleared to zero. This interrupt also marks the beginning of a PWM cycle. The user can write new duty cycle values before the timer roll-over. The TMR1 interrupt is latched into the TMR1IF bit and the TMR2 interrupt is latched into the TMR2IF bit. These flags must be cleared in software.

13.1.3.3 EXTERNAL CLOCK SOURCE

The PWMs will operate regardless of the clock source of the timer. The use of an external clock has ramifications that must be understood. Because the external TCLK12 input is synchronized internally (sampled once per instruction cycle), the time TCLK12 changes to the time the timer increments will vary by as much as 1Tcy (one instruction cycle). This will cause jitter in the duty cycle as well as the period of the PWM output.

This jitter will be $\pm 1Tcy$, unless the external clock is synchronized with the processor clock. Use of one of the PWM outputs as the clock source to the TCLK12 input, will supply a synchronized clock.

In general, when using an external clock source for PWM, its frequency should be much less than the device frequency (F_{osc}).

13.1.3.3.1 MAX RESOLUTION/FREQUENCY FOR EXTERNAL CLOCK INPUT

The use of an external clock for the PWM time-base (Timer1 or Timer2) limits the PWM output to a maximum resolution of 8-bits. The PWxDCL<7:6> bits must be kept cleared. Use of any other value will distort the PWM output. All resolutions are supported when internal clock mode is selected. The maximum attainable frequency is also lower. This is a result of the timing requirements of an external clock input for a timer (see the Electrical Specification section). The maximum PWM frequency, when the timers clock source is the RB4/TCLK12 pin, as shown in Table 13-4 (standard resolution mode).

Note 1: Other (non power-up) resets include: external reset through \overline{MCLR} and WDT Timer Reset.

13.2 Timer3

Timer3 is a 16-bit timer consisting of the TMR3H and TMR3L registers. TMR3H is the high byte of the timer and TMR3L is the low byte. This timer has an associated 16-bit period register (PR3H/CA1H:PR3L/CA1L). This period register can be software configured to be a another 16-bit capture register.

When the TMR3CS bit (TCON1<2>) is clear, the timer increments every instruction cycle ($F_{osc}/4$). When TMR3CS is set, the counter increments on every falling edge of the RB5/TCLK3 pin. In either mode, the TMR3ON bit must be set for the timer/counter to increment. When TMR3ON is clear, the timer will not increment or set flag bit TMR3IF.

Timer3 has two modes of operation, depending on the CA1/PR3 bit (TCON2<3>). These modes are:

- Three capture and one period register mode
- Four capture register mode

The PIC17C75X has up to four 16-bit capture registers that capture the 16-bit value of TMR3 when events are detected on capture pins. There are four capture pins

(RB0/CAP1, RB1/CAP2, RG4/CAP3, and RE3/CAP4), one for each capture register pair. The capture pins are multiplexed with the I/O pins. An event can be:

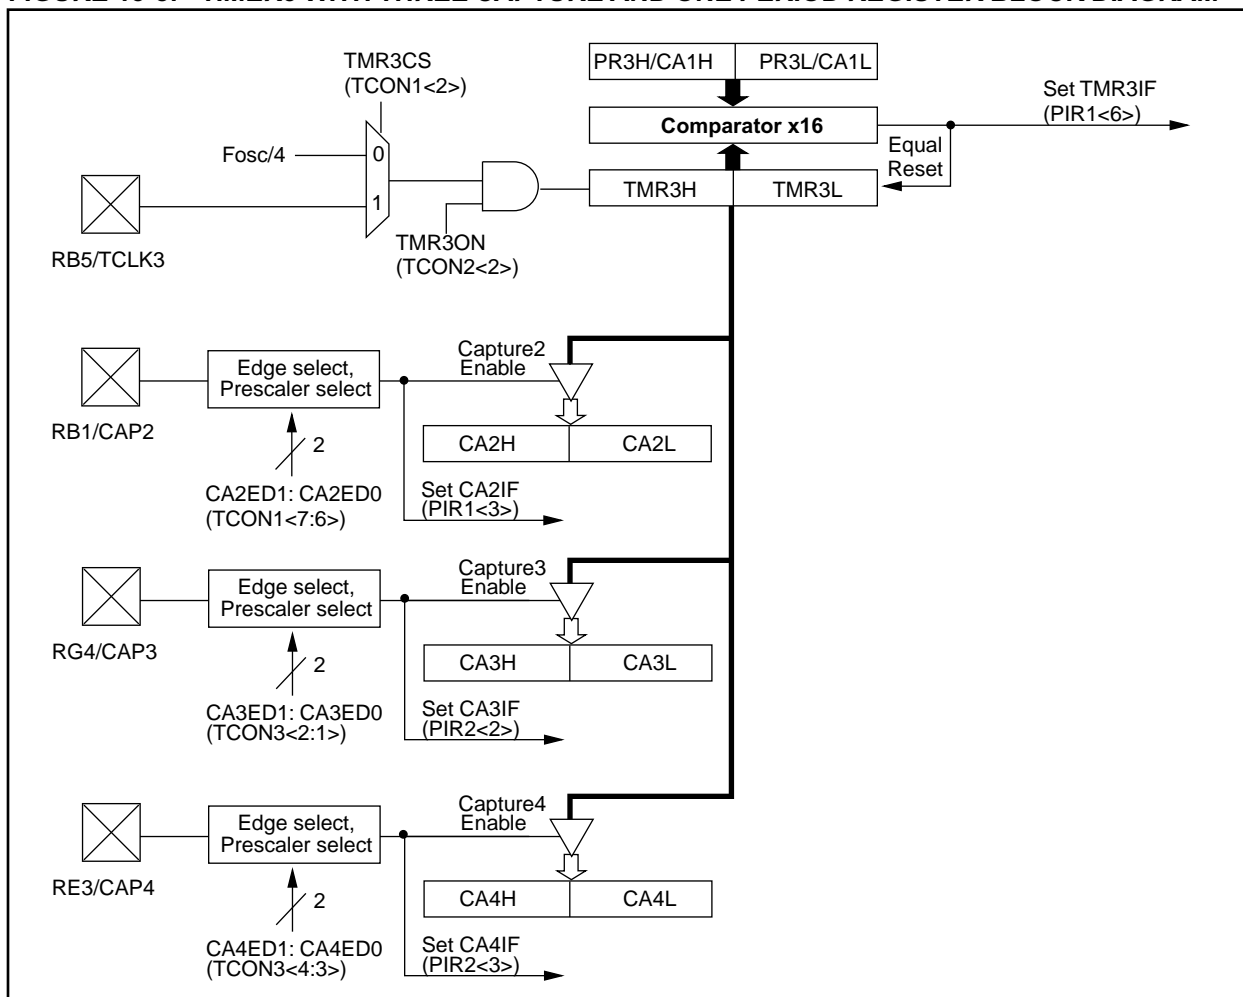

- A rising edge
- A falling edge
- Every 4th rising edge
- Every 16th rising edge

Each 16-bit capture register has an interrupt flag associated with it. The flag is set when a capture is made. The capture modules are truly part of the Timer3 block. Figure 13-8 and Figure 13-9 show the block diagrams for the two modes of operation.

13.2.1 THREE CAPTURE AND ONE PERIOD REGISTER MODE

In this mode registers PR3H/CA1H and PR3L/CA1L constitute a 16-bit period register. A block diagram is shown in Figure 13-8. The timer increments until it equals the period register and then resets to 0000h on the next timer clock. TMR3 Interrupt Flag bit (TMR3IF) is set at this point. This interrupt can be disabled by clearing the TMR3 Interrupt Enable bit (TMR3IE). TMR3IF must be cleared in software.

FIGURE 13-8: TIMER3 WITH THREE CAPTURE AND ONE PERIOD REGISTER BLOCK DIAGRAM

This mode (3 Capture, 1 Period) is selected if control bit CA1/PR3 is clear. In this mode, the Capture1 register, consisting of high byte (PR3H/CA1H) and low byte (PR3L/CA1L), is configured as the period control register for TMR3. Capture1 is disabled in this mode, and the corresponding Interrupt bit CA1IF is never set. TMR3 increments until it equals the value in the period register and then resets to 0000h on the next timer clock.

All other Captures are active in this mode.

13.2.1.1 CAPTURE OPERATION

The CAXED1 and CAXED0 bits determine the event on which capture will occur. The possible events are:

- Capture on every falling edge
- Capture on every rising edge
- Capture every 4th rising edge
- Capture every 16th rising edge

When a capture takes place, an interrupt flag is latched into the CAXIF bit. This interrupt can be enabled by setting the corresponding mask bit CAXIE. The Peripheral Interrupt Enable bit (PEIE) must be set and the Global Interrupt Disable bit (GLINTD) must be cleared for the interrupt to be acknowledged. The CAXIF interrupt flag bit is cleared in software.

When the capture prescale select is changed, the prescaler is not reset and an event may be generated. Therefore, the first capture after such a change will be ambiguous. However, it sets the time-base for the next capture. The prescaler is reset upon chip reset.

The capture pin, CAPx, is a multiplexed pin. When used as a port pin, the capture is not disabled. However, the user can simply disable the Capture interrupt by clearing CAXIE. If the CAPx pin is used as an output pin, the user can activate a capture by writing to the port pin. This may be useful during development phase to emulate a capture interrupt.

The input on the capture pin CAPx is synchronized internally to internal phase clocks. This imposes certain restrictions on the input waveform (see the Electrical Specification section for timing).

The capture overflow status flag bit is double buffered. The master bit is set if one captured word is already residing in the Capture register (CAXH:CAXL) and another "event" has occurred on the CAPx pin. The new event will not transfer the TMR3 value to the capture register, protecting the previous unread capture value. When the user reads both the high and the low bytes (in any order) of the Capture register, the master overflow bit is transferred to the slave overflow bit (CAXOVF) and then the master bit is reset. The user can then read TCONx to determine the value of CAXOVF.

The recommended sequence to read capture registers and capture overflow flag bits is shown in Example 13-1.

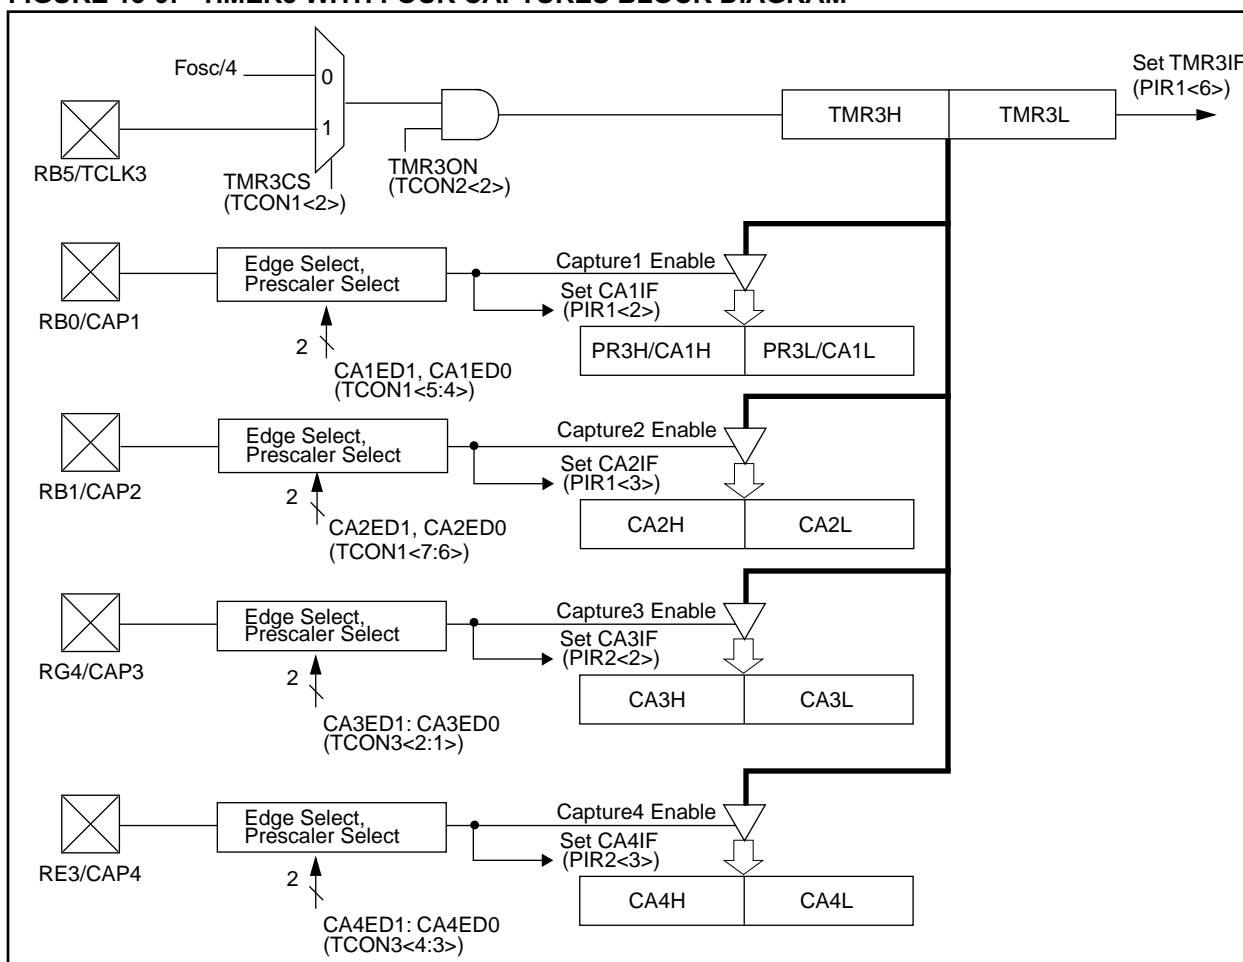

13.2.2 FOUR CAPTURE MODE

This mode is selected by setting bit CA1/PR3. A block diagram is shown in Figure 13-9. In this mode, TMR3 runs without a period register and increments from 0000h to FFFFh and rolls over to 0000h. The TMR3 interrupt Flag (TMR3IF) is set on this rollover. The TMR3IF bit must be cleared in software.

Registers PR3H/CA1H and PR3L/CA1L make a 16-bit capture register (Capture1). It captures events on pin RB0/CAP1. Capture mode is configured by the CA1ED1 and CA1ED0 bits. Capture1 Interrupt Flag bit (CA1IF) is set upon detection of the capture event. The corresponding interrupt mask bit is CA1IE. The Capture1 Overflow Status bit is CA1OVF.

All the captures operate in the same manner. Refer to Section 13.2.1 for the operation of capture.

FIGURE 13-9: TIMER3 WITH FOUR CAPTURES BLOCK DIAGRAM

13.2.3 READING THE CAPTURE REGISTERS

The Capture overflow status flag bits are double buffered. The master bit is set if one captured word is already residing in the Capture register and another “event” has occurred on the CAPx pin. The new event will not transfer the TMR3 value to the capture register, protecting the previous unread capture value. When the user reads both the high and the low bytes (in any order) of the Capture register, the master overflow bit is transferred to the slave overflow bit (CAxOVF) and then the master bit is reset. The user can then read TCONx to determine the value of CAxOVF.

An example of an instruction sequence to read capture registers and capture overflow flag bits is shown in Example 13-1. Depending on the capture source, different registers will need to be read.

EXAMPLE 13-1: SEQUENCE TO READ CAPTURE REGISTERS

```
MOVLB 3           ; Select Bank 3
MOVFPF CA2L, LO_BYTE ; Read Capture2 low byte, store in LO_BYTE
MOVFPF CA2H, HI_BYTE ; Read Capture2 high byte, store in HI_BYTE
MOVFPF TCON2, STAT_VAL ; Read TCON2 into file STAT_VAL
```

Legend: x = unknown, u = unchanged, - = unimplemented read as '0', q - value depends on condition, shaded cells are not used by Capture.

Note 1: Other (non power-up) resets include: external reset through MCLR and WDT Timer Reset.

13.2.4 EXTERNAL CLOCK INPUT FOR TIMER3

When TMR3CS is set, the 16-bit TMR3 increments on the falling edge of clock input TCLK3. The input on the RB5/TCLK3 pin is sampled and synchronized by the internal phase clocks twice every instruction cycle. This causes a delay from the time a falling edge appears on TCLK3 to the time TMR3 is actually incremented. For the external clock input timing requirements, see the Electrical Specification section. Figure 13-10 shows the timing diagram when operating from an external clock.

13.2.5 READING/WRITING TIMER3

Since Timer3 is a 16-bit timer and only 8-bits at a time can be read or written, care should be taken when reading or writing while the timer is running. The best method is to stop the timer, perform any read or write operation, and then restart Timer3 (using the TMR3ON bit). However, if it is necessary to keep Timer3 free-running, care must be taken. For writing to the 16-bit TMR3, Example 13-2 may be used. For reading the 16-bit TMR3, Example 13-3 may be used. Interrupts must be disabled during this routine.

EXAMPLE 13-2: WRITING TO TMR3

```
BSF    CPUSTA, GLINTD    ; Disable interrupts
MOVFP  RAM_L,  TMR3L     ;
MOVFP  RAM_H,  TMR3H     ;
BCF    CPUSTA, GLINTD    ; Done, enable interrupts
```

EXAMPLE 13-3: READING FROM TMR3

```
MOVFP  TMR3L, TMPLO      ; read low TMR3
MOVFP  TMR3H, TMPHI      ; read high TMR3

PIC17C75X

NOTES:

14.0 UNIVERSAL SYNCHRONOUS ASYNCHRONOUS RECEIVER TRANSMITTER (USART) MODULES

Each USART module is a serial I/O module. There are two USART modules that are available on the PIC17C75X. They are specified as USART1 and USART2. The description of the operation of these modules is generic in regard to the register names and pin names used. Table 14-1 shows the generic names that are used in the description of operation and the actual names for both USART1 and USART2. Since the control bits in each register have the same function, their names are the same (there is no need to differentiate).

The Transmit Status And Control Register (TXSTA) is shown in Figure 14-1, while the Receive Status And Control Register (RCSTA) is shown in Figure 14-2.

TABLE 14-1: USART MODULE GENERIC NAMES

Generic name	USART1 name	USART2 name
<i>Registers</i>		
RCSTA	RCSTA1	RCSTA2
TXSTA	TXSTA1	TXSTA2
SPBRG	SPBRG1	SPBRG2
RCREG	RCREG1	RCREG2
TXREG	TXREG1	TXREG2
<i>Interrupt Control Bits</i>		
RCIE	RC1IE	RC2IE
RCIF	RC1IF	RC2IF
TXIE	TX1IE	TX2IE
TXIF	TX1IF	TX2IF
<i>Pins</i>		
RX/DT	RA4/RX1/DT1	RG6/RX2/DT2
TX/CK	RA5/TX1/CK1	RG7/TX2/CK2

R = Readable bit
W = Writable bit
-n = Value at POR reset
(x = unknown)

bit 7: **CSRC:** Clock Source Select bit
Synchronous mode:
1 = Master Mode (Clock generated internally from BRG)
0 = Slave Mode (Clock from external source)
Asynchronous mode:
Don't care

bit 6: **TX9:** 9-bit Transmit Select bit
1 = Selects 9-bit transmission
0 = Selects 8-bit transmission

bit 5: **TXEN:** Transmit Enable bit
1 = Transmit enabled
0 = Transmit disabled
SREN/CREN overrides TXEN in SYNC mode

bit 4: **SYNC:** USART Mode Select bit
(Synchronous/Asynchronous)
1 = Synchronous mode
0 = Asynchronous mode

bit 3-2: **Unimplemented:** Read as '0'

bit 1: **TRMT:** Transmit Shift Register (TSR) Empty bit
1 = TSR empty
0 = TSR full

bit 0: **TX9D:** 9th bit of transmit data (can be used to calculated the parity in software)

PIC17C75X

The USART can be configured as a full duplex asynchronous system that can communicate with peripheral devices such as CRT terminals and personal computers, or it can be configured as a half duplex synchronous system that can communicate with peripheral devices such as A/D or D/A integrated circuits, Serial EEPROMs etc. The USART can be configured in the following modes:

- Asynchronous (full duplex)
- Synchronous - Master (half duplex)
- Synchronous - Slave (half duplex)

The SPEN (RCSTA<7>) bit has to be set in order to configure the I/O pins as the Serial Communication Interface.

The USART module will control the direction of the RX/DT and TX/CK pins, depending on the states of the USART configuration bits in the RCSTA and TXSTA registers. The bits that control I/O direction are:

- SPEN
- TXEN
- SREN
- CREN
- CSRC

**FIGURE 14-2: RCSTA1 REGISTER (ADDRESS: 13h, BANK 0)
RCSTA2 REGISTER (ADDRESS: 13h, BANK 4)**

R/W - 0	R/W - 0	R/W - 0	R/W - 0	U - 0	R - 0	R - 0	R - x
SPEN	RX9	SREN	CREN	—	FERR	OERR	RX9D
bit 7							bit 0

R = Readable bit
W = Writable bit
-n = Value at POR reset
(x = unknown)

bit 7: SPEN: Serial Port Enable bit
1 = Configures TX/CK and RX/DT pins as serial port pins
0 = Serial port disabled

bit 6: RX9: 9-bit Receive Select bit
1 = Selects 9-bit reception
0 = Selects 8-bit reception

bit 5: SREN: Single Receive Enable bit
This bit enables the reception of a single byte. After receiving the byte, this bit is automatically cleared.
Synchronous mode:
1 = Enable reception
0 = Disable reception
Note: This bit is ignored in synchronous slave reception.
Asynchronous mode:
Don't care

bit 4: CREN: Continuous Receive Enable bit
This bit enables the continuous reception of serial data.
Asynchronous mode:
1 = Enable continuous reception
0 = Disables continuous reception
Synchronous mode:
1 = Enables continuous reception until CREN is cleared (CREN overrides SREN)
0 = Disables continuous reception

bit 3: Unimplemented: Read as '0'

bit 2: FERR: Framing Error bit
1 = Framing error (Updated by reading RCREG)
0 = No framing error

bit 1: OERR: Overrun Error bit
1 = Overrun (Cleared by clearing CREN)
0 = No overrun error

bit 0: RX9D: 9th bit of receive data (can be the software calculated parity bit)

14.1 USART Baud Rate Generator (BRG)

The BRG supports both the Asynchronous and Synchronous modes of the USART. It is a dedicated 8-bit baud rate generator. The SPBRG register controls the period of a free running 8-bit timer. Table 14-2 shows the formula for computation of the baud rate for different USART modes. These only apply when the USART is in synchronous master mode (internal clock) and asynchronous mode.

Given the desired baud rate and Fosc, the nearest integer value between 0 and 255 can be calculated using the formula below. The error in baud rate can then be determined.

TABLE 14-2: BAUD RATE FORMULA

SYNC	Mode	Baud Rate
0	Asynchronous	$F_{OSC}/(64(X+1))$
1	Synchronous	$F_{OSC}/(4(X+1))$

X = value in SPBRG (0 to 255)

Example 14-1 shows the calculation of the baud rate error for the following conditions:

Fosc = 16 MHz

Desired Baud Rate = 9600

SYNC = 0

EXAMPLE 14-1: CALCULATING BAUD RATE ERROR

Desired Baud rate = $F_{OSC} / (64 (X + 1))$

$9600 = 16000000 / (64 (X + 1))$

$X = 25.042 = 25$

Calculated Baud Rate = $16000000 / (64 (25 + 1))$

= 9615

Error = $\frac{(\text{Calculated Baud Rate} - \text{Desired Baud Rate})}{\text{Desired Baud Rate}}$

= $(9615 - 9600) / 9600$

= 0.16%

Writing a new value to the SPBRG, causes the BRG timer to be reset (or cleared), this ensures that the BRG does not wait for a timer overflow before outputting the new baud rate.

TABLE 14-3: REGISTERS ASSOCIATED WITH BAUD RATE GENERATOR

	Address	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Value on POR, BOR	Value on all other resets (Note1)

14.2 USART Asynchronous Mode

In this mode, the USART uses standard nonreturn-to-zero (NRZ) format (one start bit, eight or nine data bits, and one stop bit). The most common data format is 8-bits. An on-chip dedicated 8-bit baud rate generator can be used to derive standard baud rate frequencies from the oscillator. The USART's transmitter and receiver are functionally independent but use the same data format and baud rate. The baud rate generator produces a clock x64 of the bit shift rate. Parity is not supported by the hardware, but can be implemented in software (and stored as the ninth data bit). Asynchronous mode is stopped during SLEEP.

The asynchronous mode is selected by clearing the SYNC bit (TXSTA<4>).

The USART Asynchronous module consists of the following important elements:

- Baud Rate Generator
- Sampling Circuit
- Asynchronous Transmitter
- Asynchronous Receiver

14.2.1 USART ASYNCHRONOUS TRANSMITTER

The USART transmitter block diagram is shown in Figure 14-3. The heart of the transmitter is the transmit shift register (TSR). The shift register obtains its data from the read/write transmit buffer (TXREG). TXREG is loaded with data in software. The TSR is not loaded until the stop bit has been transmitted from the previous load. As soon as the stop bit is transmitted, the TSR is loaded with new data from the TXREG (if available). Once TXREG transfers the data to the TSR (occurs in one Tcy at the end of the current BRG cycle), the TXREG is empty and an interrupt bit, TXIF, is set. This interrupt can be enabled/disabled by setting/clearing the TXIE bit. TXIF will be set regardless of TXIE and cannot be reset in software. It will reset only when new data is loaded into TXREG. While TXIF indicates the status of the TXREG, the TRMT (TXSTA<1>) bit shows the status of the TSR. TRMT is a read only bit which is set when the TSR is empty. No interrupt logic is tied to this bit, so the user has to poll this bit in order to determine if the TSR is empty.

Note: The TSR is not mapped in data memory, so it is not available to the user.

Transmission is enabled by setting the TXEN (TXSTA<5>) bit. The actual transmission will not occur until TXREG has been loaded with data and the baud rate generator (BRG) has produced a shift clock (Figure 14-5). The transmission can also be started by first loading TXREG and then setting TXEN. Normally when transmission is first started, the TSR is empty, so a transfer to TXREG will result in an immediate transfer to TSR resulting in an empty TXREG. A back-to-back transfer is thus possible (Figure 14-6). Clearing TXEN during a transmission will cause the transmission to be aborted. This will reset the transmitter and the TX/CK pin will revert to hi-impedance.

In order to select 9-bit transmission, the TX9 (TXSTA<6>) bit should be set and the ninth bit value should be written to TX9D (TXSTA<0>). The ninth bit value must be written before writing the 8-bit data to the TXREG. This is because a data write to TXREG can result in an immediate transfer of the data to the TSR (if the TSR is empty).

Steps to follow when setting up an Asynchronous Transmission:

1. Initialize the SPBRG register for the appropriate baud rate.
2. Enable the asynchronous serial port by clearing the SYNC bit and setting the SPEN bit.
3. If interrupts are desired, then set the TXIE bit.
4. If 9-bit transmission is desired, then set the TX9 bit.
5. Load data to the TXREG register.
6. If 9-bit transmission is selected, the ninth bit should be loaded in TX9D.
7. Enable the transmission by setting TXEN (starts transmission).

Writing the transmit data to the TXREG, then enabling the transmit (setting TXEN) allows transmission to start sooner than doing these two events in the opposite order.

Note: To terminate a transmission, either clear the SPEN bit, or the TXEN bit. This will reset the transmit logic, so that it will be in the proper state when transmit is re-enabled.

Legend: x = unknown, u = unchanged, - = unimplemented read as a '0', shaded cells are not used for asynchronous transmission.

Note 1: Other (non power-up) resets include: external reset through $\overline{\text{MCLR}}$ and Watchdog Timer Reset.

14.2.2 USART ASYNCHRONOUS RECEIVER

The receiver block diagram is shown in Figure 14-4. The data comes in the RX/DT pin and drives the data recovery block. The data recovery block is actually a high speed shifter operating at 16 times the baud rate, whereas the main receive serial shifter operates at the bit rate or at Fosc.

Once asynchronous mode is selected, reception is enabled by setting bit CREN (RCSTA<4>).

The heart of the receiver is the receive (serial) shift register (RSR). After sampling the stop bit, the received data in the RSR is transferred to the RCREG (if it is empty). If the transfer is complete, the interrupt bit, RCIF, is set. The actual interrupt can be enabled/disabled by setting/clearing the RCIE bit. RCIF is a read only bit which is cleared by the hardware. It is cleared when RCREG has been read and is empty. RCREG is a double buffered register; (i.e. it is a two deep FIFO). It is possible for two bytes of data to be received and transferred to the RCREG FIFO and a third byte begin shifting to the RSR. On detection of the stop bit of the third byte, if the RCREG is still full, then the overrun error bit, OERR (RCSTA<1>) will be set. The word in the RSR will be lost. RCREG can be read twice to retrieve the two bytes in the FIFO. The OERR bit has to be cleared in software which is done by resetting the receive logic (CREN is set). If the OERR bit is set, transfers from the RSR to RCREG are inhibited, so it is essential to clear the OERR bit if it is set. The framing error bit FERR (RCSTA<2>) is set if a stop bit is not detected.

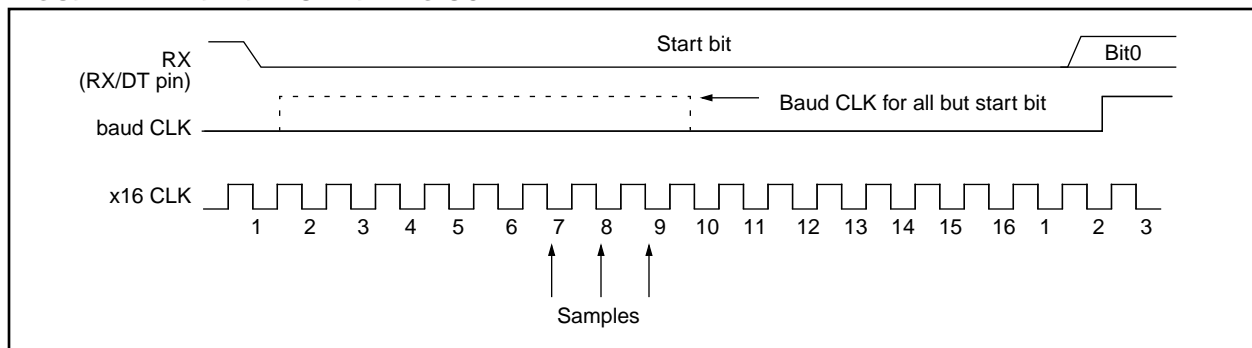

Note: The FERR and the 9th receive bit are buffered the same way as the receive data. Reading the RCREG register will allow the RX9D and FERR bits to be loaded with values for the next received data. Therefore, it is essential for the user to read the RCSTA register before reading RCREG in order not to lose the old FERR and RX9D information.

14.2.3 SAMPLING

The data on the RX/DT pin is sampled three times by a majority detect circuit to determine if a high or a low level is present at the RX/DT pin. The sampling is done on the seventh, eighth and ninth falling edges of a x16 clock (Figure 14-7).

The x16 clock is a free running clock, and the three sample points occur at a frequency of every 16 falling edges.

FIGURE 14-7: RX PIN SAMPLING SCHEME

PIC17C75X

Steps to follow when setting up an Asynchronous Reception:

1. Initialize the SPBRG register for the appropriate baud rate.
2. Enable the asynchronous serial port by clearing the SYNC bit and setting the SPEN bit.
3. If interrupts are desired, then set the RCIE bit.
4. If 9-bit reception is desired, then set the RX9 bit.
5. Enable the reception by setting the CREN bit.
6. The RCIF bit will be set when reception completes and an interrupt will be generated if the RCIE bit was set.

7. Read RCSTA to get the ninth bit (if enabled) and FERR bit to determine if any error occurred during reception.
8. Read RCREG for the 8-bit received data.
9. If an overrun error occurred, clear the error by clearing the OERR bit.

Note: To terminate a reception, either clear the SREN and CREN bits, or the SPEN bit. This will reset the receive logic, so that it will be in the proper state when receive is re-enabled.

Legend: x = unknown, u = unchanged, - = unimplemented read as a '0', shaded cells are not used for asynchronous reception.

Note 1: Other (non power-up) resets include: external reset through $\overline{\text{MCLR}}$ and Watchdog Timer Reset.

14.3 USART Synchronous Master Mode

In Master Synchronous mode, the data is transmitted in a half-duplex manner; i.e. transmission and reception do not occur at the same time: when transmitting data, the reception is inhibited and vice versa. The synchronous mode is entered by setting the SYNC (TXSTA<4>) bit. In addition, the SPEN (RCSTA<7>) bit is set in order to configure the I/O pins to CK (clock) and DT (data) lines respectively. The Master mode indicates that the processor transmits the master clock on the CK line. The Master mode is entered by setting the CSRC (TXSTA<7>) bit.

14.3.1 USART SYNCHRONOUS MASTER TRANSMISSION

The USART transmitter block diagram is shown in Figure 14-3. The heart of the transmitter is the transmit (serial) shift register (TSR). The shift register obtains its data from the read/write transmit buffer TXREG. TXREG is loaded with data in software. The TSR is not loaded until the last bit has been transmitted from the previous load. As soon as the last bit is transmitted, the TSR is loaded with new data from TXREG (if available). Once TXREG transfers the data to the TSR (occurs in one Tcy at the end of the current BRG cycle), TXREG is empty and the TXIF bit is set. This interrupt can be enabled/disabled by setting/clearing the TXIE bit. TXIF will be set regardless of the state of bit TXIE and cannot be cleared in software. It will reset only when new data is loaded into TXREG. While TXIF indicates the status of TXREG, TRMT (TXSTA<1>) shows the status of the TSR. TRMT is a read only bit which is set when the TSR is empty. No interrupt logic is tied to this bit, so the user has to poll this bit in order to determine if the TSR is empty. The TSR is not mapped in data memory, so it is not available to the user.

Transmission is enabled by setting the TXEN (TXSTA<5>) bit. The actual transmission will not occur until TXREG has been loaded with data. The first data bit will be shifted out on the next available rising edge of the clock on the TX/CK pin. Data out is stable around the falling edge of the synchronous clock (Figure 14-10). The transmission can also be started by first loading TXREG and then setting TXEN. This is advantageous when slow baud rates are selected, since BRG is kept in RESET when the TXEN, CREN, and SREN bits are clear. Setting the TXEN bit will start the BRG, creating a shift clock immediately. Normally when transmission is first started, the TSR is empty, so a transfer to TXREG will result in an immediate transfer to the TSR, resulting in an empty TXREG. Back-to-back transfers are possible.

Clearing TXEN during a transmission will cause the transmission to be aborted and will reset the transmitter. The RX/DT and TX/CK pins will revert to hi-impedance. If either CREN or SREN are set during a transmission, the transmission is aborted and the RX/DT pin reverts to a hi-impedance state (for a recep-

tion). The TX/CK pin will remain an output if the CSRC bit is set (internal clock). The transmitter logic is not reset, although it is disconnected from the pins. In order to reset the transmitter, the user has to clear the TXEN bit. If the SREN bit is set (to interrupt an ongoing transmission and receive a single word), then after the single word is received, SREN will be cleared and the serial port will revert back to transmitting, since the TXEN bit is still set. The DT line will immediately switch from hi-impedance receive mode to transmit and start driving. To avoid this, TXEN should be cleared.

In order to select 9-bit transmission, the TX9 (TXSTA<6>) bit should be set and the ninth bit should be written to TX9D (TXSTA<0>). The ninth bit must be written before writing the 8-bit data to TXREG. This is because a data write to TXREG can result in an immediate transfer of the data to the TSR (if the TSR is empty). If the TSR was empty and TXREG was written before writing the "new" TX9D, the "present" value of TX9D is loaded.

Steps to follow when setting up a Synchronous Master Transmission:

1. Initialize the SPBRG register for the appropriate baud rate (see Baud Rate Generator Section for details).
2. Enable the synchronous master serial port by setting the SYNC, SPEN, and CSRC bits.
3. Ensure that the CREN and SREN bits are clear (these bits override transmission when set).
4. If interrupts are desired, then set the TXIE bit (the GLINTD bit must be clear and the PEIE bit must be set).
5. If 9-bit transmission is desired, then set the TX9 bit.
6. Start transmission by loading data to the TXREG register.
7. If 9-bit transmission is selected, the ninth bit should be loaded in TX9D.
8. Enable the transmission by setting TXEN.

Writing the transmit data to the TXREG, then enabling the transmit (setting TXEN) allows transmission to start sooner than doing these two events in the reverse order.

Note: To terminate a transmission, either clear the SPEN bit, or the TXEN bit. This will reset the transmit logic, so that it will be in the proper state when transmit is re-enabled.

TABLE 14-8: REGISTERS ASSOCIATED WITH SYNCHRONOUS MASTER TRANSMISSION

Address	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Value on POR, BOR	Value on all other resets (Note1)

Note 1: Other (non power-up) resets include: external reset through $\overline{\text{MCLR}}$ and Watchdog Timer Reset.

FIGURE 14-9: SYNCHRONOUS TRANSMISSION

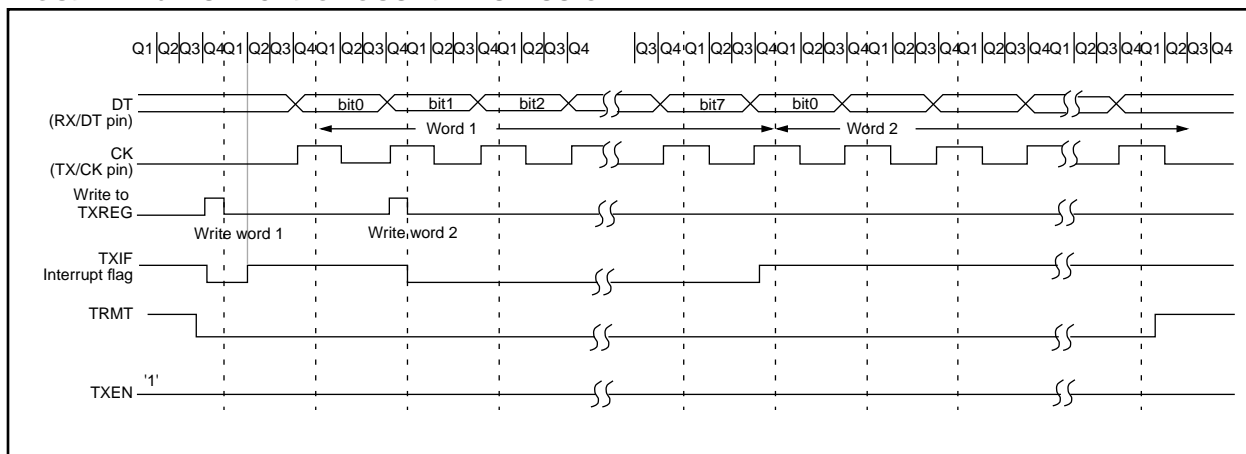

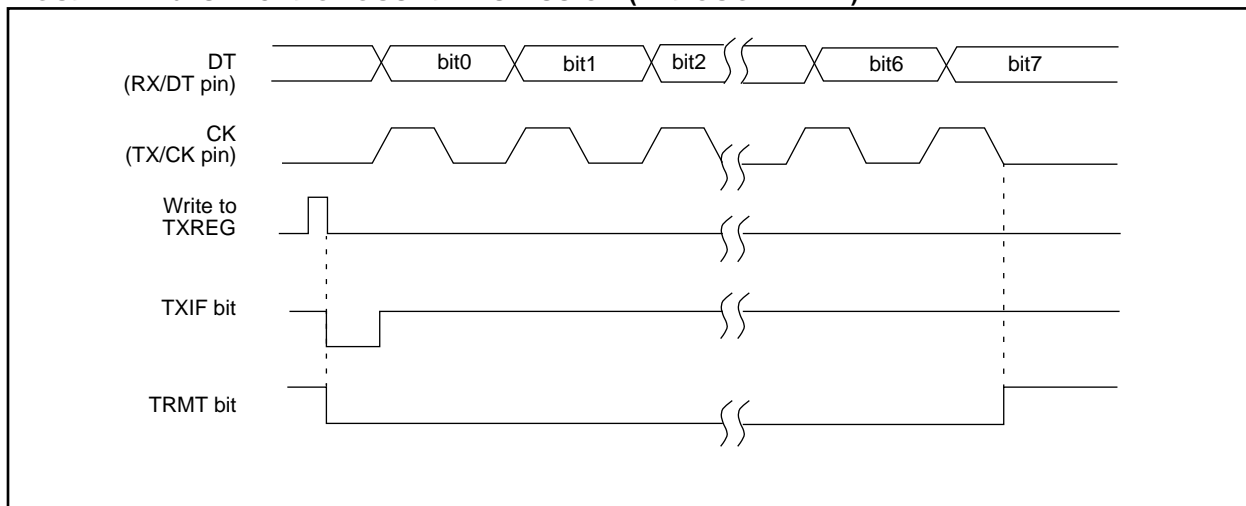

FIGURE 14-10: SYNCHRONOUS TRANSMISSION (THROUGH TXEN)

14.3.2 USART SYNCHRONOUS MASTER RECEPTION

Once synchronous mode is selected, reception is enabled by setting either the SREN (RCSTA<5>) bit or the CREN (RCSTA<4>) bit. Data is sampled on the RX/DT pin on the falling edge of the clock. If SREN is set, then only a single word is received. If CREN is set, the reception is continuous until CREN is reset. If both bits are set, then CREN takes precedence. After clocking the last bit, the received data in the Receive Shift Register (RSR) is transferred to RCREG (if it is empty). If the transfer is complete, the interrupt bit RCIF is set. The actual interrupt can be enabled/disabled by setting/clearing the RCIE bit. RCIF is a read only bit which is RESET by the hardware. In this case it is reset when RCREG has been read and is empty. RCREG is a double buffered register; i.e., it is a two deep FIFO. It is possible for two bytes of data to be received and transferred to the RCREG FIFO and a third byte to begin shifting into the RSR. On the clocking of the last bit of the third byte, if RCREG is still full, then the overrun error bit OERR (RCSTA<1>) is set. The word in the RSR will be lost. RCREG can be read twice to retrieve the two bytes in the FIFO. The OERR bit has to be cleared in software. This is done by clearing the CREN bit. If OERR is set, transfers from RSR to RCREG are inhibited, so it is essential to clear the OERR bit if it is set. The 9th receive bit is buffered the same way as the receive data. Reading the RCREG register will allow the RX9D and FERR bits to be loaded with values for the next received data; therefore, it is essential for the user to read the RCSTA register before reading RCREG in order not to lose the old FERR and RX9D information.

Steps to follow when setting up a Synchronous Master Reception:

1. Initialize the SPBRG register for the appropriate baud rate. See Section 14.1 for details.
2. Enable the synchronous master serial port by setting bits SYNC, SPEN, and CSRC.
3. If interrupts are desired, then set the RCIE bit.
4. If 9-bit reception is desired, then set the RX9 bit.
5. If a single reception is required, set bit SREN. For continuous reception set bit CREN.
6. The RCIF bit will be set when reception is complete and an interrupt will be generated if the RCIE bit was set.
7. Read RCSTA to get the ninth bit (if enabled) and determine if any error occurred during reception.
8. Read the 8-bit received data by reading RCREG.
9. If any error occurred, clear the error by clearing CREN.

Note: To terminate a reception, either clear the SREN and CREN bits, or the SPEN bit. This will reset the receive logic, so that it will be in the proper state when receive is re-enabled.

Legend: x = unknown, u = unchanged, - = unimplemented read as a '0', shaded cells are not used for synchronous master reception.

Note 1: Other (non power-up) resets include: external reset through $\overline{\text{MCLR}}$ and Watchdog Timer Reset.

14.4 USART Synchronous Slave Mode

The synchronous slave mode differs from the master mode in the fact that the shift clock is supplied externally at the TX/CK pin (instead of being supplied internally in the master mode). This allows the device to transfer or receive data in the SLEEP mode. The slave mode is entered by clearing the CSRC (TXSTA<7>) bit.

14.4.1 USART SYNCHRONOUS SLAVE TRANSMIT

The operation of the sync master and slave modes are identical except in the case of the SLEEP mode.

If two words are written to TXREG and then the SLEEP instruction executes, the following will occur. The first word will immediately transfer to the TSR and will transmit as the shift clock is supplied. The second word will remain in TXREG. TXIF will not be set. When the first word has been shifted out of TSR, TXREG will transfer the second word to the TSR and the TXIF flag will now be set. If TXIE is enabled, the interrupt will wake the chip from SLEEP and if the global interrupt is enabled, then the program will branch to interrupt vector (0020h).

Steps to follow when setting up a Synchronous Slave Transmission:

1. Enable the synchronous slave serial port by setting the SYNC and SPEN bits and clearing the CSRC bit.
2. Clear the CREN bit.
3. If interrupts are desired, then set the TXIE bit.
4. If 9-bit transmission is desired, then set the TX9 bit.
5. Start transmission by loading data to TXREG.
6. If 9-bit transmission is selected, the ninth bit should be loaded in TX9D.
7. Enable the transmission by setting TXEN.

Writing the transmit data to the TXREG, then enabling the transmit (setting TXEN) allows transmission to start sooner than doing these two events in the reverse order.

Note: To terminate a transmission, either clear the SPEN bit, or the TXEN bit. This will reset the transmit logic, so that it will be in the proper state when transmit is re-enabled.

14.4.2 USART SYNCHRONOUS SLAVE RECEPTION

Operation of the synchronous master and slave modes are identical except in the case of the SLEEP mode. Also, SREN is a don't care in slave mode.

If receive is enabled (CREN) prior to the SLEEP instruction, then a word may be received during SLEEP. On completely receiving the word, the RSR will transfer the data to RCREG (setting RCIF) and if the RCIE bit is set, the interrupt generated will wake the chip from SLEEP. If the global interrupt is enabled, the program will branch to the interrupt vector (0020h).

Steps to follow when setting up a Synchronous Slave Reception:

1. Enable the synchronous master serial port by setting the SYNC and SPEN bits and clearing the CSRC bit.
2. If interrupts are desired, then set the RCIE bit.
3. If 9-bit reception is desired, then set the RX9 bit.
4. To enable reception, set the CREN bit.
5. The RCIF bit will be set when reception is complete and an interrupt will be generated if the RCIE bit was set.
6. Read RCSTA to get the ninth bit (if enabled) and determine if any error occurred during reception.
7. Read the 8-bit received data by reading RCREG.
8. If any error occurred, clear the error by clearing the CREN bit.

Note: To abort reception, either clear the SPEN bit, the SREN bit (when in single receive mode), or the CREN bit (when in continuous receive mode). This will reset the receive logic, so that it will be in the proper state when receive is re-enabled.

15.0 SYNCHRONOUS SERIAL PORT (SSP) MODULE

The Synchronous Serial Port (SSP) module is a serial interface useful for communicating with other peripheral or microcontroller devices. These peripheral devices may be serial EEPROMs, shift registers, display drivers, A/D converters, etc. The SSP module can operate in one of two modes:

- Serial Peripheral Interface (SPI)
- Inter-Integrated Circuit (I²C)

Refer to Application Note AN578, "Use of the SSP Module in the I²C Multi-Master Environment."

Figure 15-1, Figure 15-2, and Figure 15-3 show the block diagrams for the three different modes of operation.

FIGURE 15-1: SPI MODE BLOCK DIAGRAM

FIGURE 15-2: I²C SLAVE MODE BLOCK DIAGRAM

FIGURE 15-3: I²C MASTER MODE BLOCK DIAGRAM

FIGURE 15-4: SSPSTAT: SYNC SERIAL PORT STATUS REGISTER (ADDRESS: 13h, BANK 6)

R/W-0	R/W-0	R-0	R-0	R-0	R-0	R-0	R-0
SMP	CKE	D/A	P	S	R/W	UA	BF
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, read as '0'
- n = Value at POR reset

bit 7: **SMP**: SPI data input sample phase
SPI Master Mode
1 = Input data sampled at end of data output time
0 = Input data sampled at middle of data output time
SPI Slave Mode
SMP must be cleared when SPI is used in slave mode
In I²C master or slave mode:
1 = Slew rate control disabled for standard speed mode (100 kHz and 1 MHz)
0 = Slew rate control enabled for high speed mode (400 kHz)

bit 6: **CKE**: SPI Clock Edge Select (Figure 15-8, Figure 15-11, and Figure 15-12)
CKP = 0
1 = Data transmitted on rising edge of SCK
0 = Data transmitted on falling edge of SCK
CKP = 1
1 = Data transmitted on falling edge of SCK
0 = Data transmitted on rising edge of SCK

bit 5: **D/A**: Data/Address bit (I²C slave mode only)
1 = Indicates that the last byte received or transmitted was data
0 = Indicates that the last byte received or transmitted was address

bit 4: **P**: Stop bit (I²C mode only. This bit is cleared when the SSP module is disabled, SSPEN is cleared)
1 = Indicates that a stop bit has been detected last (this bit is '0' on RESET)
0 = Stop bit was not detected last

bit 3: **S**: Start bit (I²C mode only. This bit is cleared when the SSP module is disabled, SSPEN is cleared)
1 = Indicates that a start bit has been detected last (this bit is '0' on RESET)
0 = Start bit was not detected last

bit 2: **R/W**: Read/Write bit information (I²C mode only)
This bit holds the R/W bit information following the last address match. This bit is only valid from the address match to the next start bit, stop bit, or \overline{ACK} bit.
In I²C slave mode:
1 = Read
0 = Write
In I²C master mode:
1 = Transmit is in progress
0 = Transmit is not in progress. Or'ing this bit with SAE, RCE, SPE, or AKE will indicate if the SSP is in IDLE mode.

bit 1: **UA**: Update Address (10-bit I²C slave mode only)
1 = Indicates that the user needs to update the address in the SSPADD register
0 = Address does not need to be updated

bit 0: **BF**: Buffer Full Status bit
Receive (SPI and I²C modes)
1 = Receive complete, SSPBUF is full
0 = Receive not complete, SSPBUF is empty
Transmit (I²C mode only)
1 = Data Transmit in progress (does not include \overline{ACK} and stop bits), SSPBUF is full
0 = Data Transmit complete (does not include \overline{ACK} and stop bits), SSPBUF is empty

FIGURE 15-5: SSPCON1: SYNC SERIAL PORT CONTROL REGISTER1 (ADDRESS 11h, BANK 6)

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0
WCOL	SSPOV	SSPEN	CKP	SSPM3	SSPM2	SSPM1	SSPM0
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, read as '0'
- n = Value at POR reset

bit 7: **WCOL:** Write Collision Detect bit
Master Mode:
1 = A write to the SSPBUF register was attempted while the I²C conditions were not valid for a transmission to be started
0 = No collision
Slave Mode:
1 = The SSPBUF register is written while it is still transmitting the previous word (must be cleared in software)
0 = No collision

bit 6: **SSPOV:** Receive Overflow Indicator bit
In SPI mode
1 = A new byte is received while the SSPBUF register is still holding the previous data. In case of overflow, the data in SSPSR is lost. Overflow can only occur in slave mode. The user must read the SSPBUF, even if only transmitting data, to avoid setting overflow. In master mode the overflow bit is not set since each new reception (and transmission) is initiated by writing to the SSPBUF register.
0 = No overflow
In I²C mode
1 = A byte is received while the SSPBUF register is still holding the previous byte. SSPOV is a "don't care" in transmit mode. SSPOV must be cleared in software in either mode.
0 = No overflow

bit 5: **SSPEN:** Synchronous Serial Port Enable bit
In SPI mode
1 = Enables serial port and configures SCK, SDO, and SDI as serial port pins
0 = Disables serial port and configures these pins as I/O port pins
In I²C mode
1 = Enables the serial port and configures the SDA and SCL pins as serial port pins
0 = Disables serial port and configures these pins as I/O port pins
Note: In both modes, when enabled, these pins must be properly configured as input or output.

bit 4: **CKP:** Clock Polarity Select bit
In SPI mode
1 = Idle state for clock is a high level
0 = Idle state for clock is a low level
In I²C slave mode
SCK release control
1 = Enable clock
0 = Holds clock low (clock stretch) (Used to ensure data setup time)
In I²C master mode
Unused in this mode

bit 3-0: **SSPM3:SSPM0:** Synchronous Serial Port Mode Select bits
0000 = SPI master mode, clock = Fosc/4
0001 = SPI master mode, clock = Fosc/16
0010 = SPI master mode, clock = Fosc/64
0011 = SPI master mode, clock = TMR2 output/2
0100 = SPI slave mode, clock = SCK pin. \overline{SS} pin control enabled.
0101 = SPI slave mode, clock = SCK pin. \overline{SS} pin control disabled. \overline{SS} can be used as I/O pin
0110 = I²C slave mode, 7-bit address
0111 = I²C slave mode, 10-bit address
1000 = I²C master mode, clock = Fosc / (4 * (SSPAD+1))
1xx1 = Reserved
1x1x = Reserved

FIGURE 15-6: SSPCON2: SYNC SERIAL PORT CONTROL REGISTER2 (ADDRESS 12h, BANK 6)

R/W-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0
GCEN	ACKSTAT	ACKDT	ACKEN	RCEN	PEN	RSEN	SEN
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, Read as '0'
- n = Value at POR reset

bit 7: **GCEN:** General Call Enable bit (In I²C slave mode only)
1 = Enable interrupt when a general call address is received in the SSPSR.
0 = General call address disabled.

bit 6: **ACKSTAT:** Acknowledge Status bit (In I²C master mode only)
In master transmit mode:
1 = Acknowledge was not received from slave
0 = Acknowledge was received from slave

bit 5: **ACKDT:** Acknowledge Data bit (In I²C master mode only)
In master receive mode:
Value that will be transmitted when the user initiates an Acknowledge sequence at the end of a receive.
1 = Not Acknowledge
0 = Acknowledge

bit 4: **ACKEN:** Acknowledge Sequence Enable bit (In I²C master mode only).
In master receive mode:
1 = Initiate Acknowledge sequence on SDA and SCL pins, and transmit AKD data bit. Automatically cleared by hardware.
0 = Acknowledge sequence idle
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

bit 3: **RCEN:** Receive Enable bit (In I²C master mode only).
1 = Enables Receive mode for I²C
0 = Receive idle
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

bit 2: **PEN:** Stop Condition Enable bit (In I²C master mode only).
SCK release control
1 = Initiate Stop condition on SDA and SCL pins. Automatically cleared by hardware.
0 = Stop condition idle
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

bit 1: **RSEN:** Restart Condition Enabled bit (In I²C master mode only)
1 = Initiate Restart condition on SDA and SCL pins. Automatically cleared by hardware.
0 = Restart condition idle.
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

bit 0: **SEN:** Start Condition Enabled bit (In I²C master mode only)
1 = Initiate Start condition on SDA and SCL pins. Automatically cleared by hardware.
0 = Start condition idle.
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

15.1 SPI Mode

The SPI mode allows 8-bits of data to be synchronously transmitted and received simultaneously. All four modes of SPI are supported. To accomplish communication, typically three pins are used:

- Serial Data Out (SDO)
- Serial Data In (SDI)
- Serial Clock (SCK)

Additionally a fourth pin may be used when in a slave mode of operation:

- Slave Select (\overline{SS})

When initializing the SPI, several options need to be specified. This is done by programming the appropriate control bits in the SSPCON1 register (SSPCON1<5:0>) and SSPSTAT<7:6>. These control bits allow the following to be specified:

- Master Mode (SCK is the clock output)
- Slave Mode (SCK is the clock input)
- Clock Polarity (Idle state of SCK)
- Data input sample phase (middle or end of data output time)
- Clock edge (output data on rising/falling edge of SCK)
- Clock Rate (Master mode only)
- Slave Select Mode (Slave mode only)

The SSP consists of a transmit/receive Shift Register (SSPSR) and a buffer register (SSPBUF). The SSPSR shifts the data in and out of the device, MSb first. The SSPBUF holds the data that was written to the SSPSR, until the received data is ready. Once the 8-bits of data have been received, that byte is moved to the SSPBUF register. Then the buffer full detect bit BF (SSPSTAT<0>) and the interrupt flag bit SSPIF (PIR2<7>) are set. This double buffering of the received data (SSPBUF) allows the next byte to start reception before reading the data that was just received. Any write to the SSPBUF register during transmission/reception of data will be ignored, and the write collision detect bit WCOL (SSPCON1<7>) will be set. User software must clear the WCOL bit so that it can be determined if the following write(s) to the SSPBUF register completed successfully.

When the application software is expecting to receive valid data, the SSPBUF should be read before the next byte of data to transfer is written to the SSPBUF. Buffer full bit BF (SSPSTAT<0>) indicates when SSPBUF has been loaded with the received data (transmission is complete). When the SSPBUF is read, bit BF is cleared. This data may be irrelevant if the SPI is only a transmitter. Generally the SSP Interrupt is used to determine when the transmission/reception has completed. The SSPBUF must be read and/or written. If the interrupt method is not going to be used, then software polling can be done to ensure that a write collision does not occur. Example 15-1 shows the loading of the SSPBUF (SSPSR) for data transmission. The shaded instruction is only required if the received data is meaningful.

EXAMPLE 15-1: LOADING THE SSPBUF (SSPSR) REGISTER

```

MOVLB 6           ; Bank 6
LOOP BTFSS SSPSTAT, BF ; Has data been
                    ; received
                    ; (transmit
                    ; complete)?
GOTO LOOP         ; No
MOVFPF SSPBUF, RXDATA ; Save in user RAM
MOVFPF TXDATA, SSPBUF ; New data to xmit

```

The block diagram of the SSP module, when in SPI mode (Figure 15-7), shows that the SSPSR is not directly readable or writable, and can only be accessed by addressing the SSPBUF register. Additionally, the SSP status register (SSPSTAT) indicates the various status conditions.

FIGURE 15-7: SSP BLOCK DIAGRAM (SPI MODE)

To enable the serial port, SSP Enable bit, SSPEN (SSPCON1<5>) must be set. To reset or reconfigure SPI mode, clear bit SSPEN, re-initialize the SSPCON registers, and then set bit SSPEN. This configures the SDI, SDO, SCK, and \overline{SS} pins as serial port pins. For the pins to behave as the serial port function, some must have their data direction bits (in the DDR register) appropriately programmed. That is:

- SDI is automatically controlled by the SPI module
- SDO must have DDRB<7> cleared
- SCK (Master mode) must have DDRB<6> cleared
- SCK (Slave mode) must have DDRB<6> set
- \overline{SS} must have PORTA<2> set

Note: The \overline{SS} pin must be configured as an input for the slave select to operate. This is done by writing a '1' to PORTA<2>.

Any serial port function that is not desired may be overridden by programming the corresponding data direction (DDR) register to the opposite value. An example would be in master mode where you are only sending data (to a display driver), then both SDI and \overline{SS} could be used as general purpose open drain outputs by writing a '0'.

Figure 15-9 shows a typical connection between two microcontrollers. The master controller (Processor 1) initiates the data transfer by sending the SCK signal. Data is shifted out of both shift registers on their programmed clock edge, and latched on the opposite edge of the clock. Both processors should be programmed to same Clock Polarity (CKP), then both controllers would send and receive data at the same time. Whether the data is meaningful (or dummy data) depends on the application software. This leads to three scenarios for data transmission:

- Master sends data — Slave sends dummy data
- Master sends data — Slave sends data
- Master sends dummy data — Slave sends data

15.1.1 MASTER MODE

The master can initiate the data transfer at any time because it controls the SCK. The master determines when the slave (Processor 2, Figure 15-9) is to broadcast data by the software protocol.

In master mode the data is transmitted/received as soon as the SSPBUF register is written to. If the SPI is only going to receive, the SCK output could be disabled (programmed as an input). The SSPSR register will continue to shift in the signal present on the SDI pin at the programmed clock rate. As each byte is received, it will be loaded into the SSPBUF register as if a normal received byte (interrupts and status bits appropriately set). This could be useful in receiver applications as a "line activity monitor" mode.

The clock polarity is selected by appropriately programming bit CKP (SSPCON1<4>). This then would give waveforms for SPI communication as shown in Figure 15-8, Figure 15-11, and Figure 15-12 where the

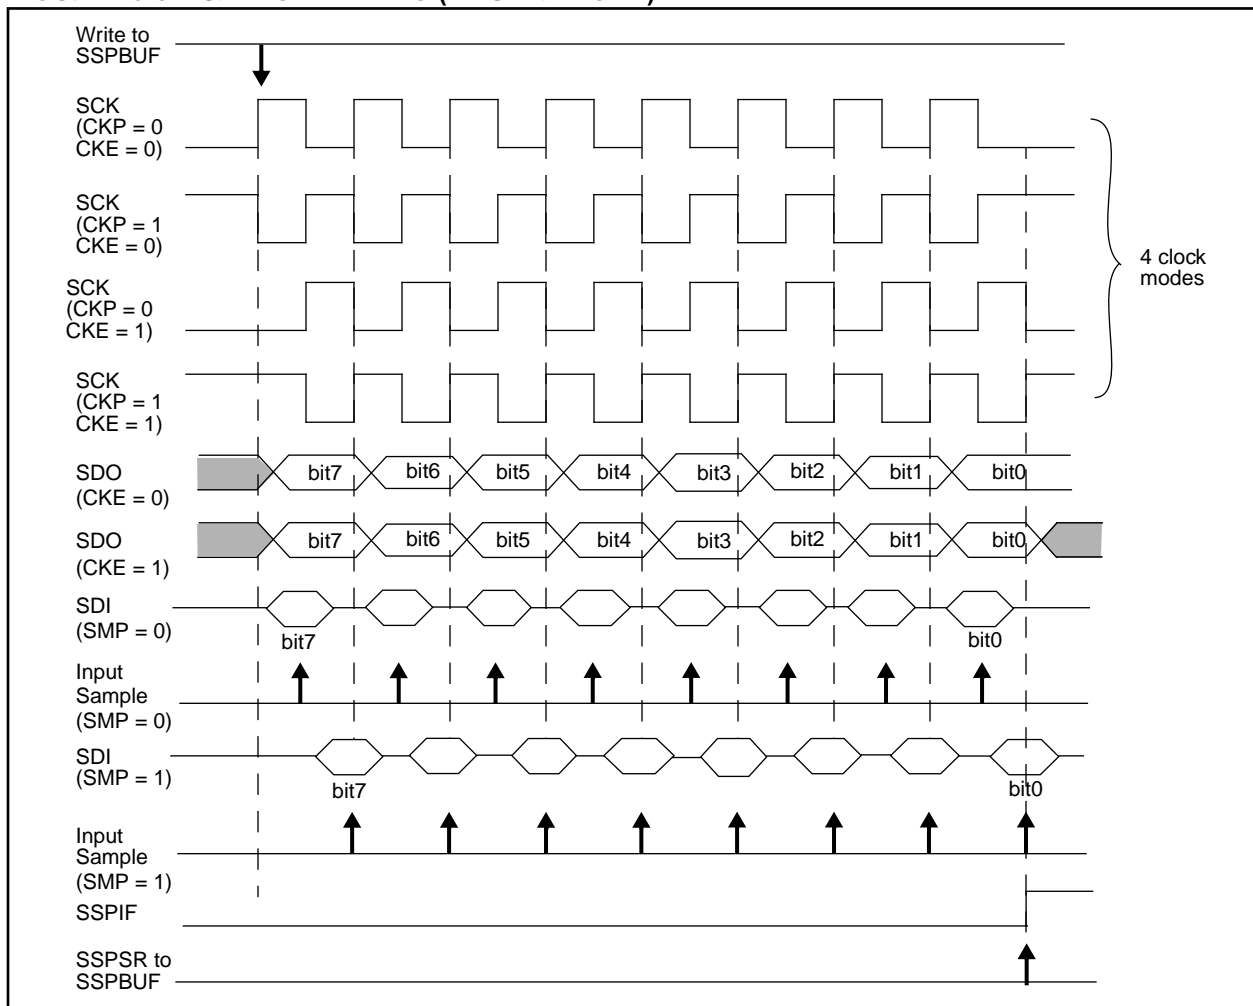

MSB is transmitted first. In master mode, the SPI clock rate (bit rate) is user programmable to be one of the following:

- $F_{osc}/4$ (or T_{CY})
- $F_{osc}/16$ (or $4 \cdot T_{CY}$)
- $F_{osc}/64$ (or $16 \cdot T_{CY}$)
- $\text{Timer2 output}/2$

This allows a maximum bit clock frequency (at 33 MHz) of 8.25 MHz.

Figure 15-8 Shows the waveforms for master mode. When $CKE = 1$, the SDO data is valid before there is a clock edge on SCK. The change of the input sample is shown based on the state of the SMP bit. The time when the SSPBUF is loaded with the received data is shown.

FIGURE 15-8: SPI MODE TIMING (MASTER MODE)

15.1.2 SLAVE MODE

In slave mode, the data is transmitted and received as the external clock pulses appear on SCK. When the last bit is latched the interrupt flag bit SSPIF (PIR2<7>) is set.

While in slave mode the external clock is supplied by the external clock source on the SCK pin. This external clock must meet the minimum high and low times as specified in the electrical specifications.

While in sleep mode, the slave can transmit/receive data and wake the device from sleep.

15.1.3 SLAVE SELECT SYNCHRONIZATION

The \overline{SS} pin allows a synchronous slave mode. The SPI must be in slave mode with \overline{SS} pin control enabled (SSPCON1<3:0> = 04h). The pin must not be driven low for the \overline{SS} pin to function as an input. The RA2 Data Latch must be high. When the \overline{SS} pin is low, transmission and reception are enabled and the SDO pin is driven. When the \overline{SS} pin goes high, the SDO pin is no longer driven, even if in the middle of a transmitted byte, and becomes a floating output. External pull-up/ pull-down resistors may be desirable, depending on the application.

Note: When the SPI is in Slave Mode with \overline{SS} pin control enabled, (SSPCON<3:0> = 0100) the SPI module will reset if the \overline{SS} pin is set to VDD.

Note: If the SPI is used in Slave Mode with CKE = '1', then the \overline{SS} pin control must be enabled.

To emulate two-wire communication, the SDO pin can be connected to the SDI pin. When the SPI needs to operate as a receiver the SDO pin can be configured as an input. This disables transmissions from the SDO. The SDI can always be left as an input (SDI function) since it cannot create a bus conflict.

In Figure 15-11 the \overline{SS} pin terminates the transmission/reception. The SSPIF bit is set after the last edge of the SCK. In Figure 15-12 the \overline{SS} pin causes the first bit of the data to be output. The SSPIF bit is set after the last SCK edge.

Note 1: Other (non power-up) resets include: external reset through MCLR and Watchdog Timer Reset.

15.2 SSP I²C Operation

The SSP module in I²C mode fully implements all master and slave functions (including general call support) and provides interrupts on start and stop bits in hardware to determine a free bus (multi-master function). The SSP module implements the standard mode specifications as well as 7-bit and 10-bit addressing. Appendix E gives an overview of the I²C bus specification.

FIGURE 15-13: SSP BLOCK DIAGRAM (I²C MODE)

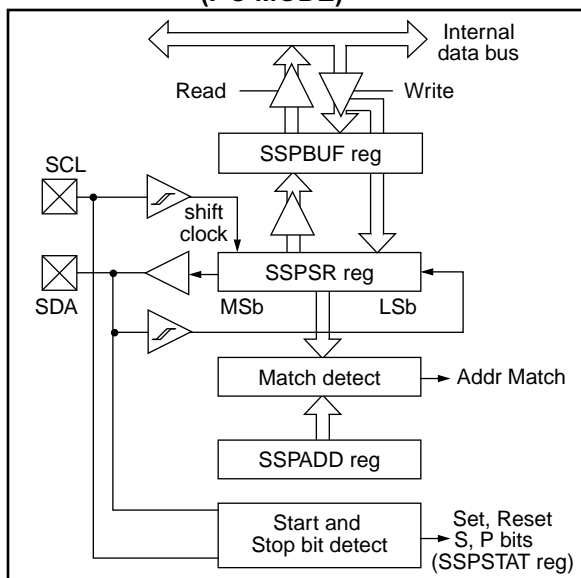

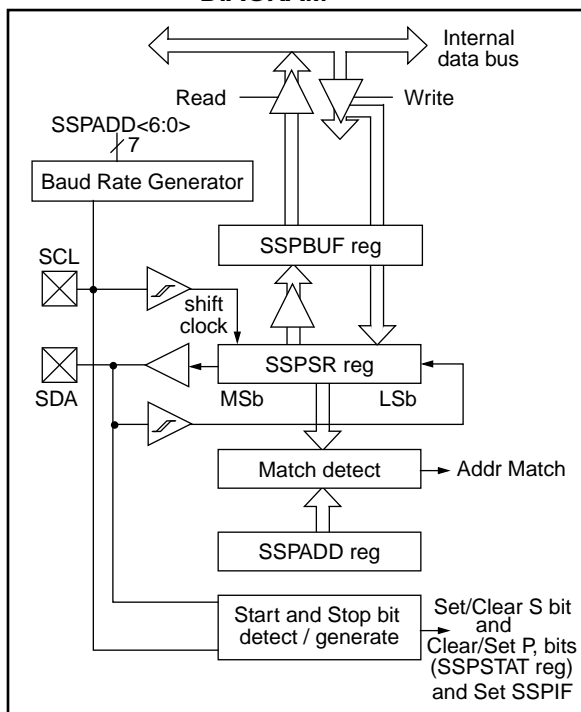

FIGURE 15-14: I²C MASTER MODE BLOCK DIAGRAM

Two pins are used for data transfer. These are the SCL pin, which is the clock, and the SDA pin, which is the data. Pins that are on PortA are automatically configured when the I²C mode is enabled. The SSP module functions are enabled by setting SSP Enable bit SSPEN (SSPCON1<5>).

The SSP module has six registers for I²C operation. These are the:

- SSP Control Register1 (SSPCON1)
- SSP Control Register2 (SSPCON2)
- SSP Status Register (SSPSTAT)
- Serial Receive/Transmit Buffer (SSPBUF)
- SSP Shift Register (SSPSR) - Not directly accessible
- SSP Address Register (SSPADD)

The SSPCON1 register allows control of the I²C operation. Four mode selection bits (SSPCON1<3:0>) allow one of the following I²C modes to be selected:

- I²C Slave mode (7-bit address)
- I²C Slave mode (10-bit address)
- I²C Master mode, clock = OSC/4 (SSPADD +1)

Selection of any I²C mode, with the SSPEN bit set, forces the SCL and SDA pins to be open drain. These pins are on PORTA and therefore there is no need to program to be inputs.

The SSPSTAT register gives the status of the data transfer. This information includes detection of a START or STOP bit, specifies if the received byte was data or address if the next byte is the completion of 10-bit address, and if this will be a read or write data transfer.

The SSPBUF is the register to which transfer data is written to or read from. The SSPSR register shifts the data in or out of the device. In receive operations, the SSPBUF and SSPSR create a doubled buffered receiver. This allows reception of the next byte to begin before reading the last byte of received data. When the complete byte is received, it is transferred to the SSPBUF register and flag bit SSPIF is set. If another complete byte is received before the SSPBUF register is read, a receiver overflow has occurred and bit SSPOV (SSPCON1<6>) is set and the byte in the SSPSR is lost.

The SSPADD register holds the slave address. In 10-bit mode, the user needs to write the high byte of the address (1111 0 A9 A8 0). Following the high byte address match, the low byte of the address needs to be loaded (A7:A0).

15.2.1 SLAVE MODE

In slave mode, the SCL and SDA pins must be configured as inputs. The SSP module will override the input state with the output data when required (slave-transmitter).

When an address is matched or the data transfer after an address match is received, the hardware automatically will generate the acknowledge (\overline{ACK}) pulse, and then load the SSPBUF register with the received value currently in the SSPSR register.

There are certain conditions that will cause the SSP module not to give this \overline{ACK} pulse. These are if either (or both):

- The buffer full bit BF (SSPSTAT<0>) was set before the transfer was received.
- The overflow bit SSPOV (SSPCON1<6>) was set before the transfer was received.

In this case, the SSPSR register value is not loaded into the SSPBUF, but bit SSPIF (PIR2<7>) is set. Table 15-2 shows what happens when a data transfer byte is received, given the status of bits BF and SSPOV. The shaded cells show the condition where user software did not properly clear the overflow condition. Flag bit BF is cleared by reading the SSPBUF register while bit SSPOV is cleared through software.

The SCL clock input must have a minimum high and low time for proper operation. The high and low times of the I²C specification as well as the requirement of the SSP module is shown in timing parameter #100 and parameter #101.

15.2.1.1 ADDRESSING

Once the SSP module has been enabled, it waits for a START condition to occur. Following the START condition, the 8-bits are shifted into the SSPSR register. All incoming bits are sampled with the rising edge of the clock (SCL) line. The value of register SSPSR<7:1> is compared to the value of the SSPADD register. The address is compared on the falling edge of the eighth clock (SCL) pulse. If the addresses match, and the BF and SSPOV bits are clear, the following events occur:

- The SSPSR register value is loaded into the SSPBUF register.
- The buffer full bit, BF is set.
- An \overline{ACK} pulse is generated.
- SSP interrupt flag bit, SSPIF (PIR2<7>) is set (interrupt is generated if enabled) - on the falling edge of the ninth SCL pulse.

In 10-bit address mode, two address bytes need to be received by the slave. The five Most Significant bits (MSBs) of the first address byte specify if this is a 10-bit address. Bit R/ \overline{W} (SSPSTAT<2>) must specify a write so the slave device will receive the second address byte. For a 10-bit address the first byte would equal '1111 0 A9 A8 0', where A9 and A8 are the two MSBs of the address. The sequence of events for a 10-bit address is as follows, with steps 7- 9 for slave-transmitter:

- Receive first (high) byte of Address (bits SSPIF, BF, and bit UA (SSPSTAT<1>) are set).
- Update the SSPADD register with second (low) byte of Address (clears bit UA and releases the SCL line).
- Read the SSPBUF register (clears bit BF) and clear flag bit SSPIF.
- Receive second (low) byte of Address (bits SSPIF, BF, and UA are set).
- Update the SSPADD register with the first (high) byte of Address, if match occurs releases the SCL line, this will clear bit UA.
- Read the SSPBUF register (clears bit BF) and clear flag bit SSPIF.
- Receive repeated START condition.
- Receive first (high) byte of Address (bits SSPIF and BF are set).
- Read the SSPBUF register (clears bit BF) and clear flag bit SSPIF.

Note: Following the RESTART condition (step 7) in 10-bit mode, the user only needs to match the first 7-bit address. The user does not update the SSPADD for the second half of the address.

TABLE 15-2: DATA TRANSFER RECEIVED BYTE ACTIONS

Status Bits as Data Transfer is Received		SSPSR → SSPBUF	Generate \overline{ACK} Pulse	Set bit SSPIF (SSP Interrupt occurs if enabled)
BF	SSPOV			
0	0	Yes	Yes	Yes
1	0	No	No	Yes
1	1	No	No	Yes
0	1	No	No	Yes

15.2.1.2 SLAVE RECEPTION

When the R/\overline{W} bit of the address byte is clear and an address match occurs, the R/\overline{W} bit of the SSPSTAT register is cleared. The received address is loaded into the SSPBUF register.

When the address byte overflow condition exists, then no acknowledge (\overline{ACK}) pulse is given. An overflow condition is defined as either bit BF (SSPSTAT<0>) is set or bit SSPOV (SSPCON1<6>) is set.

An SSP interrupt is generated for each data transfer byte. Flag bit SSPIF (PIR2<7>) must be cleared in software. The SSPSTAT register is used to determine the status of the byte.

Note: The SSPBUF will be loaded if the SSPOV bit = 1 and the BF flag = 0. If a read of the SSPBUF was performed, but the user did not clear the state of the SSPOV bit before the next receive occurred. The \overline{ACK} is not sent and the SSPBUF is updated.

15.2.1.3 SLAVE TRANSMISSION

When the R/\overline{W} bit of the incoming address byte is set and an address match occurs, the R/\overline{W} bit of the SSPSTAT register is set. The received address is loaded into the SSPBUF register. The \overline{ACK} pulse will be sent on the ninth bit, and the SCL pin is held low. The transmit data must be loaded into the SSPBUF register, which also loads the SSPSR register. Then SCL pin should be enabled by setting bit CKP (SSPCON1<4>). The master must monitor the SCL pin prior to asserting another clock pulse. The slave devices may be holding off the master by stretching the clock. The eight data bits are shifted out on the falling edge of the SCL input. This ensures that the SDA signal is valid during the SCL high time (Figure 15-16).

FIGURE 15-15: I²C WAVEFORMS FOR RECEPTION (7-BIT ADDRESS)

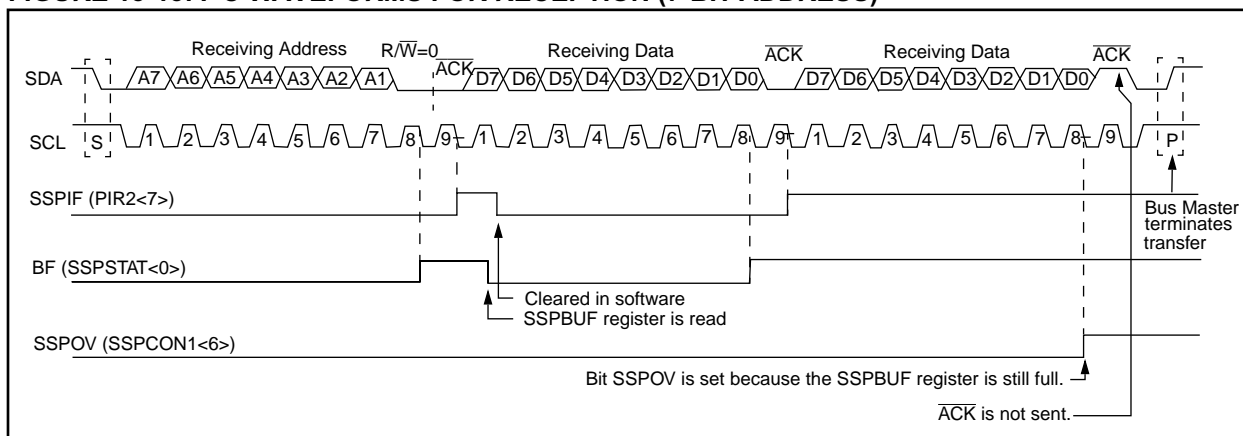

FIGURE 15-16: I²C WAVEFORMS FOR TRANSMISSION (7-BIT ADDRESS)

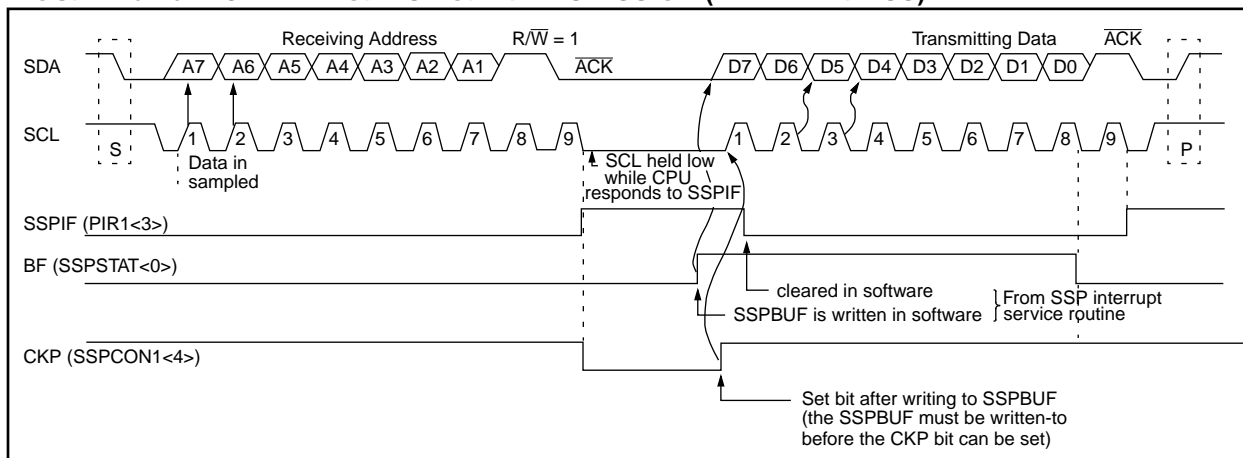

FIGURE 15-17: I²C SLAVE-TRANSMITTER (10-BIT ADDRESS)

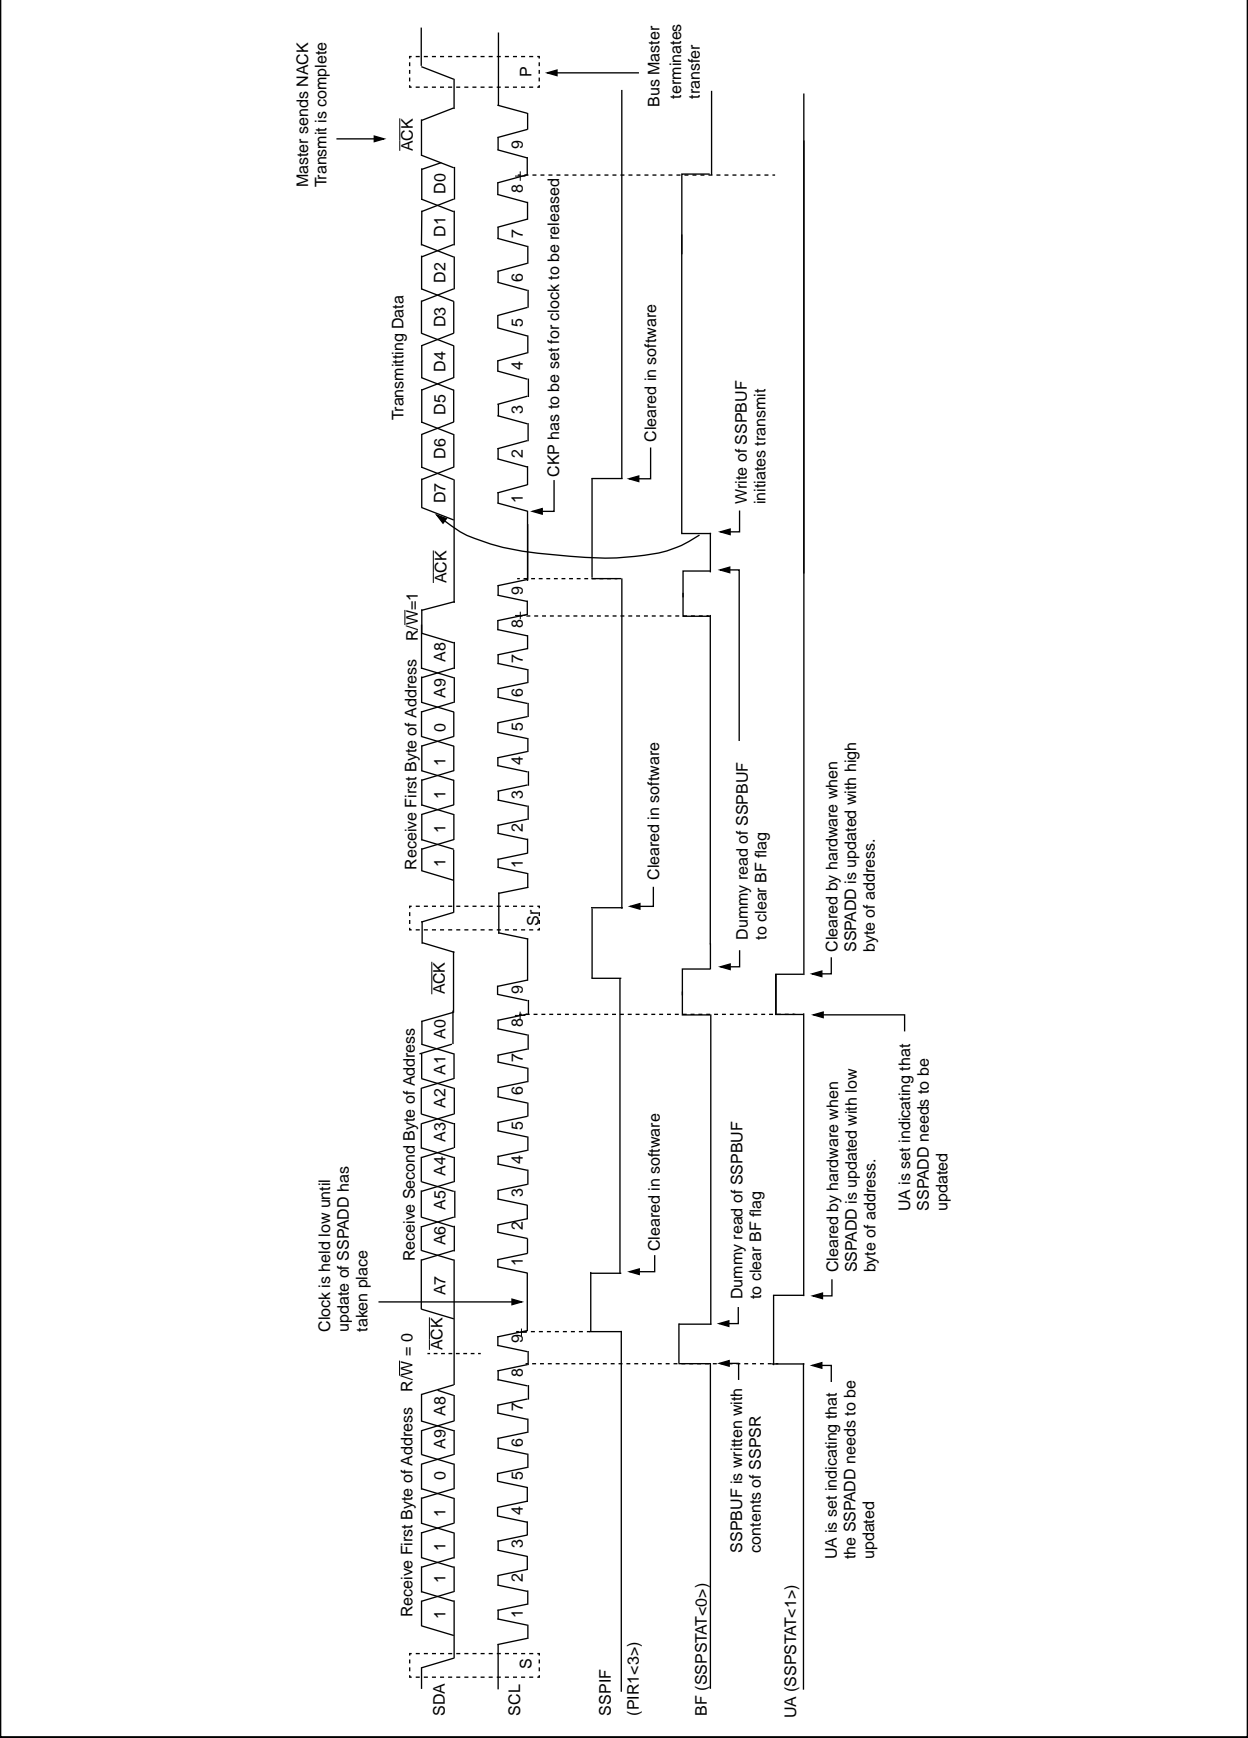

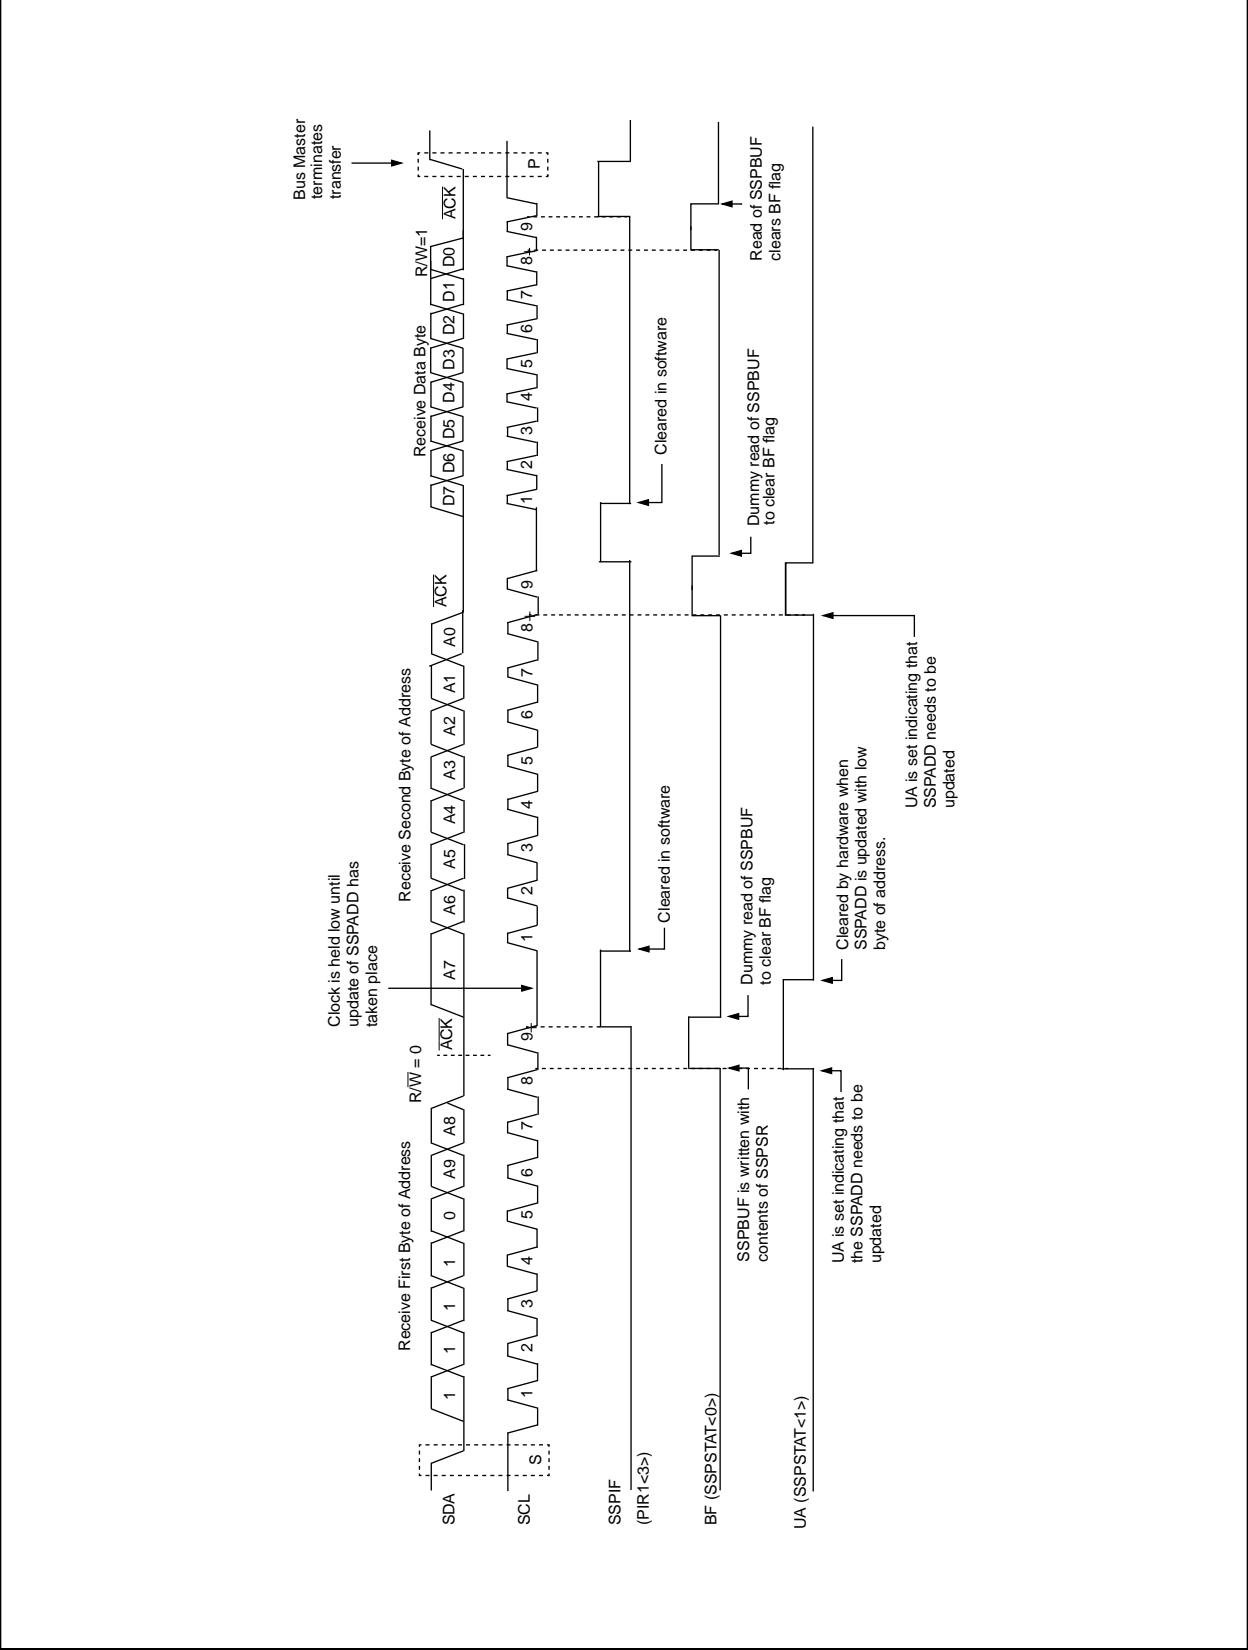

FIGURE 15-18: I²C SLAVE-RECEIVER (10-BIT ADDRESS)

An SSP interrupt is generated for each data transfer byte. Flag bit SSPIF must be cleared in software, and the SSPSTAT register is used to determine the status of the byte. Flag bit SSPIF is set on the falling edge of the ninth clock pulse.

As a slave-transmitter, the \overline{ACK} pulse from the master-receiver is latched on the rising edge of the ninth SCL input pulse. If the SDA line was high (not \overline{ACK}), then the data transfer is complete. When the \overline{ACK} is latched by the slave, the slave logic is reset and the slave then monitors for another occurrence of the START bit. If the SDA line was low (\overline{ACK}), the transmit data must be loaded into the SSPBUF register, which also loads the SSPSR register. Then the SCL pin should be enabled by setting bit CKP.

15.2.2 GENERAL CALL ADDRESS SUPPORT

The addressing procedure for the I²C bus is such that the first byte after the START condition usually determines which device will be the slave addressed by the master. The exception is the general call address which can address all devices. When this address is used, all devices should, in theory, respond with an acknowledge.

The general call address is one of eight addresses reserved for specific purposes by the I²C protocol. It consists of all 0's with $R/\overline{W} = 0$.

The general call address is recognized when the General Call Enable bit (GCEN) is enabled (SSPCON2<7> = 1). Following a start-bit detect, 8-bits are shifted into SSPSR and the address is compared against SSPADD, and is also compared to the general call address, fixed in hardware.

If the general call address matches, the SSPSR is transferred to the SSPBUF, the BF flag is set (eighth bit), and on the falling edge of the ninth bit (\overline{ACK} bit) the SSPIF interrupt is set.

When the interrupt is serviced. The source for the interrupt can be checked by reading the contents of the SSPBUF to determine if the address was device specific or a general call address.

In 10-bit mode, the SSPADD is required to be updated for the second half of the address to match, and the UA bit is set (SSPSTAT<1>). If the general call address is sampled when GCEN = 1 while the slave is configured in 10-bit address mode, then the second half of the address is not necessary, the UA bit will not be set, and the slave will begin receiving data after the acknowledge (Figure 15-19).

FIGURE 15-19: GENERAL CALL ADDRESS SEQUENCE (7 OR 10-BIT MODE)

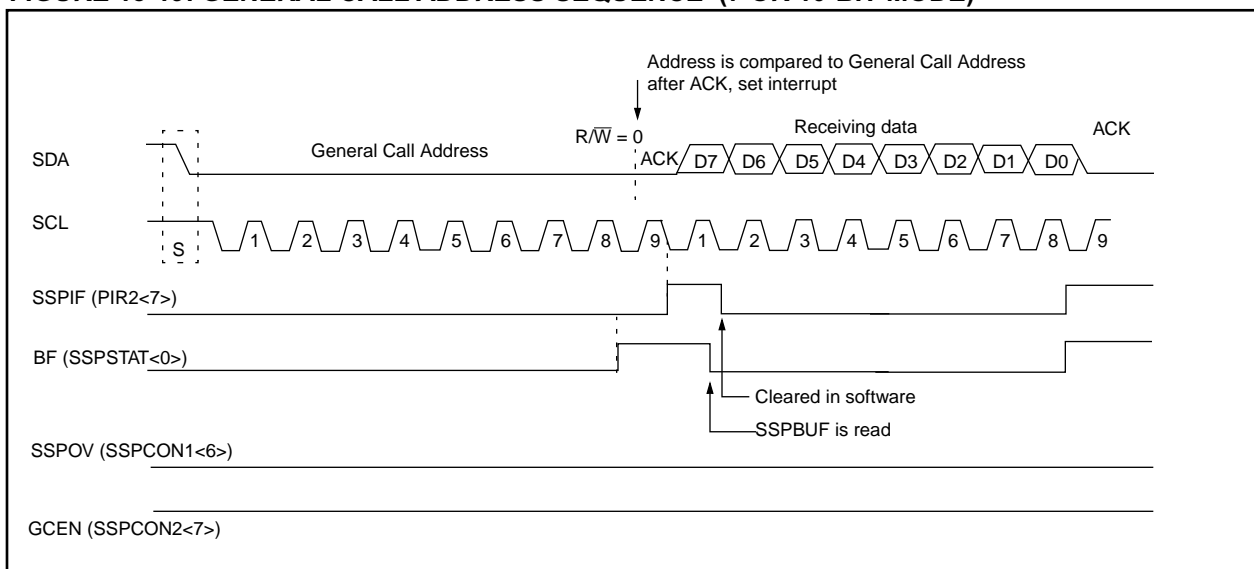

TABLE 15-3: REGISTERS ASSOCIATED WITH I²C OPERATION

Address	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Value on POR, BOR	Value on all other resets (Note 1)

Legend: x = unknown, u = unchanged, - = unimplemented read as '0'. Shaded cells are not used by the SSP in I²C mode.

Note 1: Other (non power-up) resets include: external reset through MCLR and Watchdog Timer Reset.

15.2.4 MULTI-MASTER MODE

In multi-master mode, the interrupt generation on the detection of the START and STOP conditions allows the determination of when the bus is free. The STOP (P) and START (S) bits are cleared from a reset or when the SSP module is disabled. Control of the I²C bus may be taken when bit P (SSPSTAT<4>) is set, or the bus is idle with both the S and P bits clear. When the bus is busy, enabling the SSP Interrupt will generate the interrupt when the STOP condition occurs.

In multi-master operation, the SDA line must be monitored to see if the signal level is the expected output level. This check is performed in hardware, with the result placed in the BCLIF bit.

The states where arbitration can be lost are:

- Address Transfer
- Data Transfer
- A Start Condition
- A Restart Condition
- An Acknowledge Condition

15.2.5 I²C MASTER MODE SUPPORT

Master Mode is enabled by setting and clearing the appropriate SSPM bits in SSPCON1 and by setting the SSPEN bit. Once master mode is enabled, the user has six options.

- Assert a start condition on SDA and SCL.
- Assert a restart condition on SDA and SCL.
- Write to the SSPBUF register initiating transmission of data/address.
- Generate a stop Condition on SDA and SCL.
- Configure the I²C port to receive data.
- Generate an acknowledge condition at the end of a received byte of data.

Note: The SSP Module when configured in I²C Master Mode does not allow queueing of events. For instance: The user is not allowed to initiate a start condition, and immediately write the SSPBUF register to initiate transmission before the START condition is complete. In this case the SSPBUF will not be written to, and the WCOL bit will be set, indicating that a write to the SSPBUF did not occur.

15.2.5.1 I²C MASTER MODE OPERATION

The master device generates all of the serial clock pulses and the START and STOP conditions. A transfer is ended with a STOP condition or with a repeated START condition. Since the repeated START condition is also the beginning of the next serial transfer, the I²C bus will not be released.

In Master transmitter mode serial data is output through SDA, while SCL outputs the serial clock. The first byte transmitted contains the slave address of the receiving device, (7 bits) and the data direction bit. In this case the data direction bit (R/ \overline{W}) will be logic '0'. Serial data is transmitted 8 bits at a time. After each byte is transmitted, an acknowledge bit is received. START and STOP conditions are output to indicate the beginning and the end of a serial transfer.

In Master receive mode the first byte transmitted contains the slave address of the transmitting device (7 bits) and the data direction bit. In this case the data direction bit (R/ \overline{W}) will be logic '1'. Thus the first byte transmitted is a 7-bit slave address followed by a '1' to indicate receive bit. Serial data is received via SDA while SCL outputs the serial clock. Serial data is received 8 bits at a time. After each byte is received, an acknowledge bit is transmitted. START and STOP conditions indicate the beginning and end of transmission.

The baud rate generator used for SPI mode operation is now used to set the SCL clock frequency for either 100 kHz, 400 kHz, or 1 MHz I²C operation. The baud rate generator reload value is contained in the lower 7 bits of the SSPADD register. The baud rate generator will automatically begin counting on a write to the SSPBUF. Once the given operation is complete (i.e. transmission of the last data bit is followed by ACK) the internal clock will automatically stop counting and the SCL pin will remain in its last state

A typical transmit sequence would go as follows:

1. The user generates a Start Condition by setting the START enable bit (SEN) in SSPCON2.
2. SSPIF is set. The module will wait the required start time before any other operation takes place.
3. The user loads the SSPBUF with address to transmit.
4. Address is shifted out the SDA pin until all 8 bits are transmitted.
5. The SSP Module shifts in the ACK bit from the slave device, and writes its value into the SSPCON2 register (SSPCON2<6>).
6. The module generates an interrupt at the end of the ninth clock cycle by setting SSPIF.
7. The user loads the SSPBUF with eight bits of data.
8. DATA is shifted out the SDA pin until all 8 bits are transmitted.

9. The SSP Module shifts in the ACK bit from the slave device, and writes its value into the SSPCON2 register (SSPCON2<6>).
10. The module generates an interrupt at the end of the ninth clock cycle by setting SSPIF.
11. The user generates a STOP condition by setting the STOP enable bit PEN in SSPCON2.

15.2.6 BAUD RATE GENERATOR

In I²C master mode, the reload value for the BRG is located in the lower 7 bits of the SSPADD register (Figure 15-21). When the BRG is loaded with this value, the BRG counts down to 0 and stops until another reload has taken place. In I²C master mode, the BRG is not reloaded automatically. If Clock Arbitration is taking place for instance, the BRG will be reloaded when the SCL pin is sampled high (Figure 15-22).

FIGURE 15-21: BAUD RATE GENERATOR BLOCK DIAGRAM

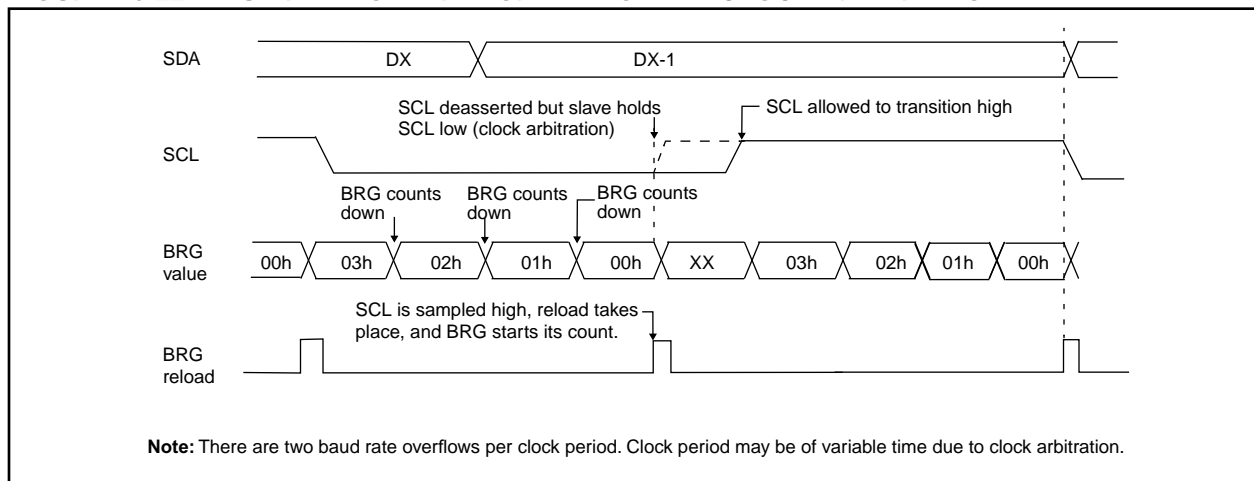

FIGURE 15-22: BAUD RATE GENERATOR TIMING WITH CLOCK ARBITRATION

15.2.7 I²C MASTER MODE START CONDITION TIMING

To initiate a START condition the user sets the start condition enable bit or SEN bit (SSPCON2<0>). If the SDA and SCL pins are sampled high, the baud rate generator is re-loaded with the contents of SSPADD<6:0>, and starts its count. If SCL and SDA are both sampled high when the baud rate generator times out (T_{BRG}), the SDA pin is driven low. The action of the SDA being driven low while SCL is high is the START condition, and causes the S bit (SSPSTAT<3>) to be set. Since the I²C module is configured in master mode, a '1' in the S bit causes the SSPIF flag to be set. Following this, the baud rate generator is reloaded with the contents of SSPADD<6:0> and resumes its count. When the baud rate generator times out (T_{BRG}) the SEN bit in the SSPCON2 register will be automatically cleared, the baud rate generator is suspended leaving the SDA line held low, and the START condition is complete.

Note: If at the beginning of START condition the SDA and SCL pins are already sampled low, or if during the START condition the SCL line is sampled low before the SDA line is driven low, a bus collision occurs, the Bus Collision Interrupt Flag (BCLIF) is set, the START condition is aborted, and the I²C module is reset into its IDLE state.

15.2.7.1 WCOL STATUS FLAG

If the user writes the SSPBUF when an START sequence is in progress, then WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

Note: Because queueing of events is not allowed, writing to the lower 5 bits of SSPCON2 is disabled until the START condition is complete.

FIGURE 15-23: FIRST START BIT TIMING

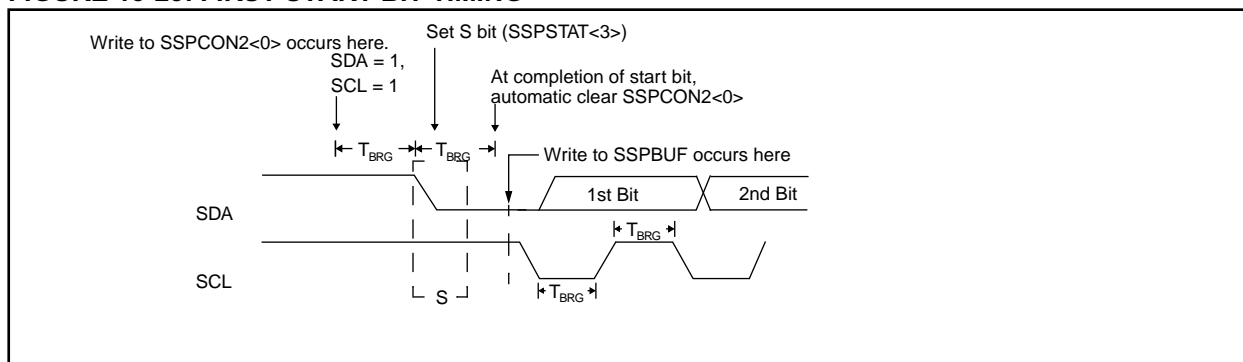

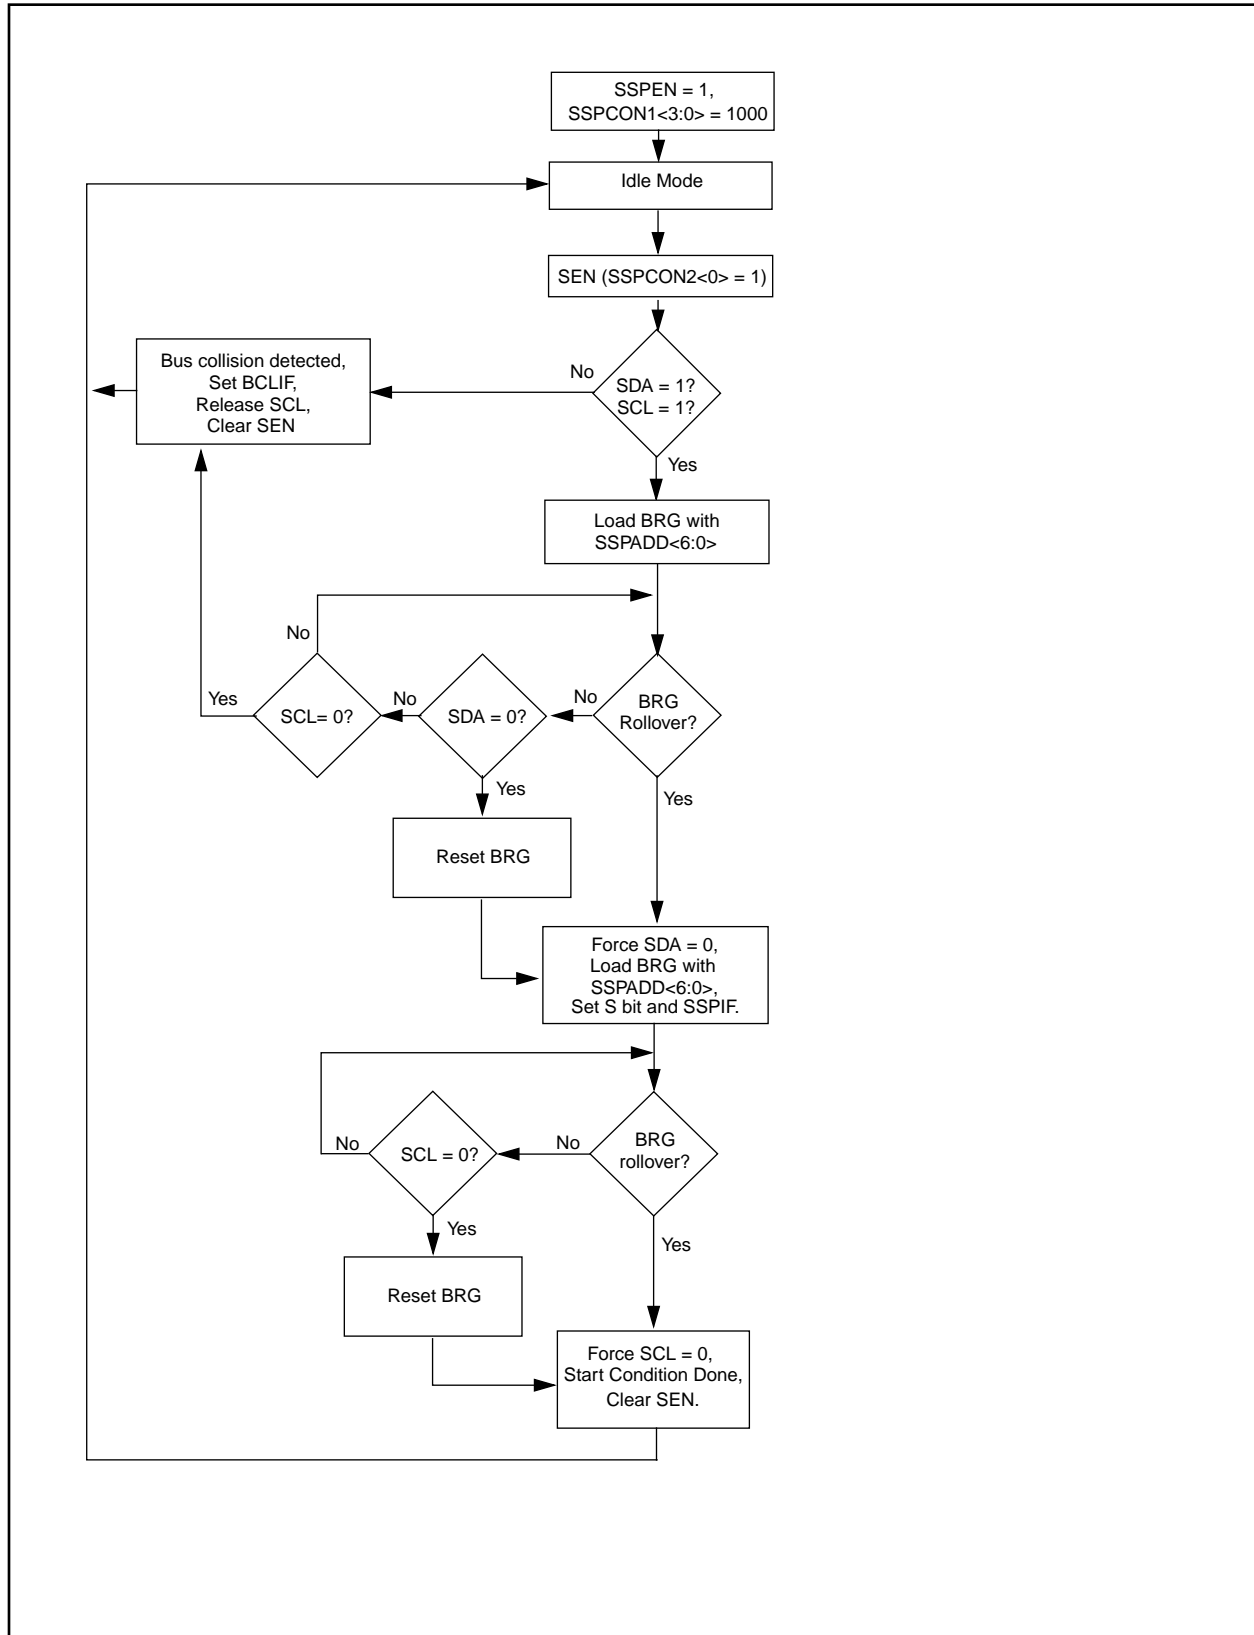

FIGURE 15-24: START CONDITION FLOWCHART

15.2.8 I²C MASTER MODE RESTART CONDITION TIMING

A RESTART condition occurs when the RSEN bit (SSPCON2<1>) is programmed high and the SSP module is in the idle state. When the RSEN bit is set, the SCL pin is asserted low. When the SCL pin is sampled low, the baud rate generator is loaded with the contents of SSPADD<5:0>, and begins counting. The SDA pin is released (brought high) for one baud rate generator count (T_{BRG}). When the baud rate generator times out, if SDA is sampled high, the SCL pin will be de-asserted (brought high). When SCL is sampled high the baud rate generator is re-loaded with the contents of SSPADD<6:0> and begins counting. SDA and SCL must be sampled high for one T_{BRG} . This action is then followed by assertion of the SDA pin (SDA = 0) for one T_{BRG} while SCL = 1. Following this, the RSEN bit in the SSPCON2 register will be automatically cleared, and the baud rate generator is not reloaded, leaving the SDA pin held low. As soon as a start condition is detected on the SDA and SCL pins, the S bit (SSPSTAT<3>) will be set. The SSPIF bit will not be set until the baud rate generator has timed-out.

Note 1: If the RSEN is programmed while a transmit is in progress, it will not take effect.

Note 2: A bus collision during the RESTART condition occurs if:

- SDA is sampled low when SCL goes from low to high.
- SCL goes low before SDA is asserted low. This may indicate that another master is attempting to transmit a data "1".

Immediately following the SSPIF bit getting set, the user may write the SSPBUF with the 7-bit address in 7-bit mode, or the default first address in 10-bit mode. After the first eight bits are transmitted and an ACK is received, the user may then transmit an additional eight bits of address (10-bit mode) or eight bits of data (7-bit mode).

After the write to the SSPBUF, each bit of address will be shifted out on the falling edge of SCL until all seven address bits and the R/\overline{W} bit are completed. On the falling edge of the eighth clock the master will de-assert the SDA pin allowing the slave to respond with an acknowledge. On the falling edge of the ninth clock the master will sample the SDA pin to see if the address was recognized by a slave. The status of the ACK bit is programmed into the AKSTAT status bit SSPCON2<6>. Following the falling edge of the ninth clock transmission of the address, the SSPIF is set, the BF flag is cleared, and the baud rate generator is turned off until another write to the SSPBUF takes place, holding SCL low and allowing SDA to float.

15.2.8.1 WCOL STATUS FLAG

If the user writes the SSPBUF when a RESTART sequence is in progress, then WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

Note: Because queueing of events is not allowed, writing of the lower 5 bits of SSPCON2 is disabled until the RESTART condition is complete.

FIGURE 15-25: REPEAT START CONDITION TIMING

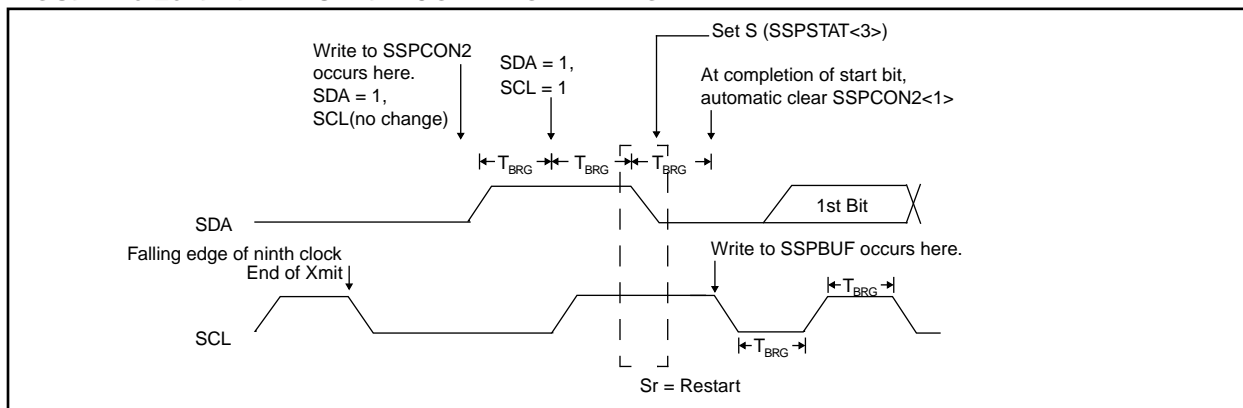

FIGURE 15-26: RESTART CONDITION FLOWCHART (PAGE 1)

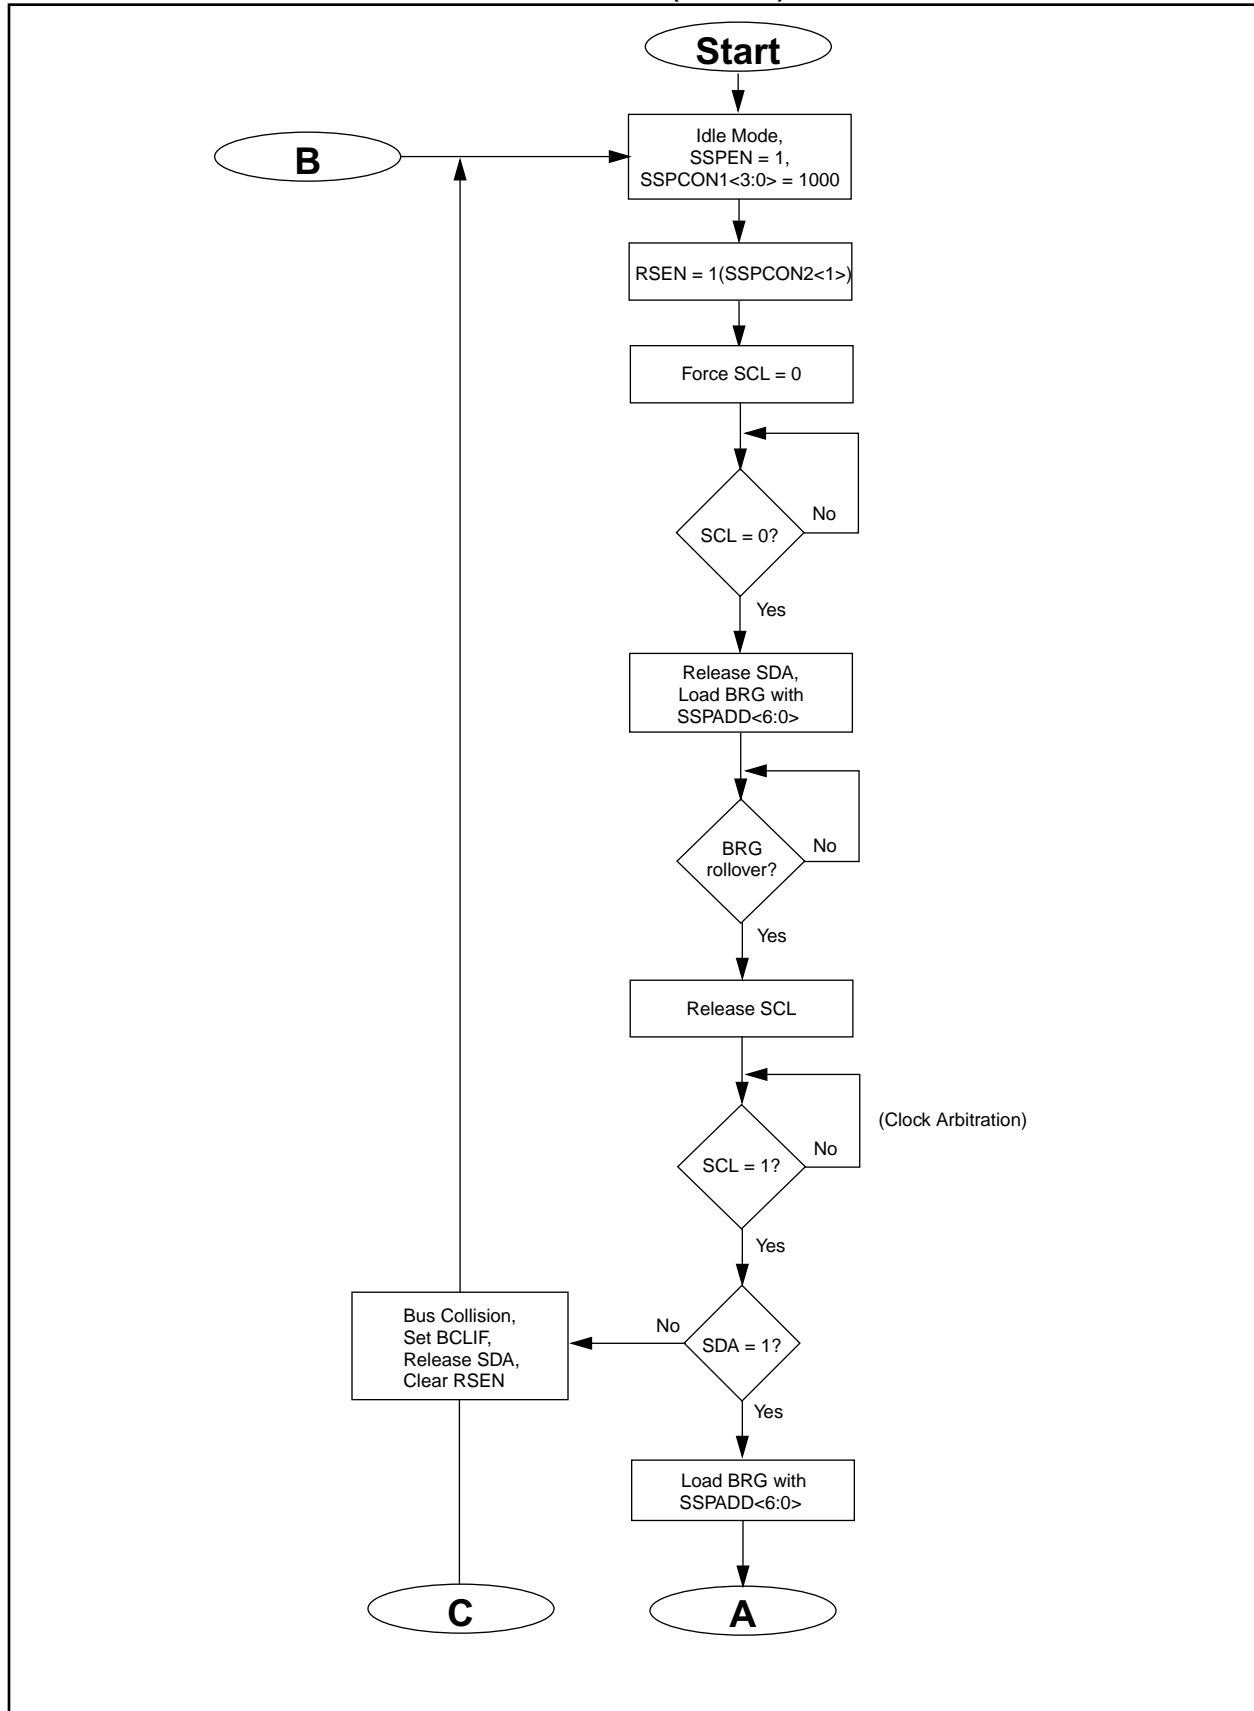

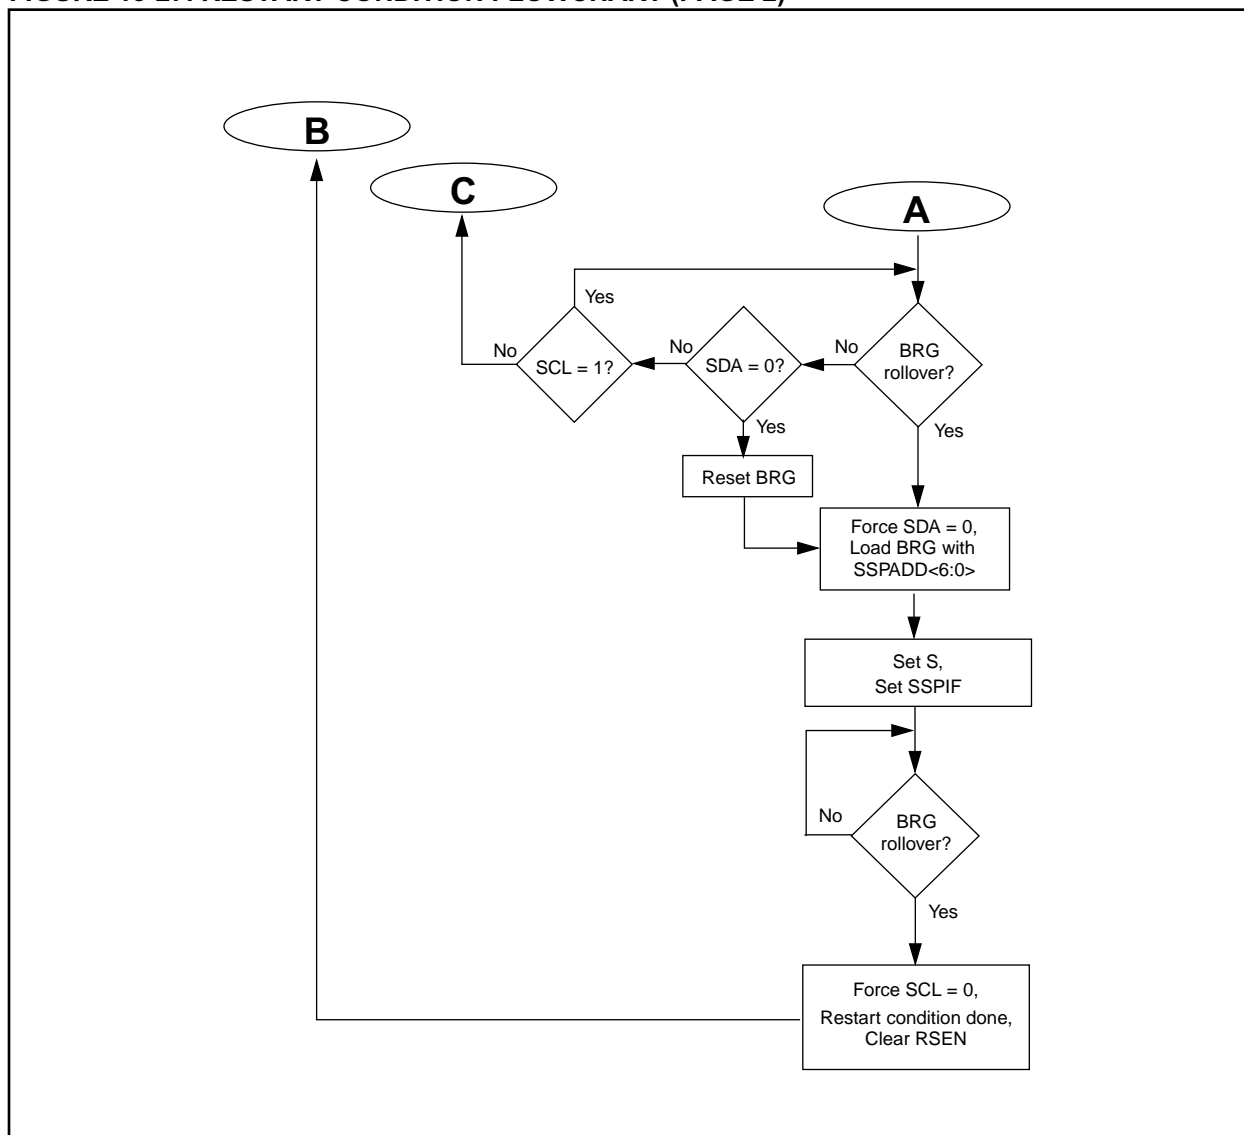

FIGURE 15-27: RESTART CONDITION FLOWCHART (PAGE 2)

15.2.9 I²C MASTER MODE TRANSMISSION

Transmission of a data byte, a 7-bit address, or the either half of a 10-bit address is accomplished by simply writing a value to SSPBUF register. This action will set the buffer full flag (BF) and allow the baud rate generator to begin counting and start the next transmission. Each bit of address/data will be shifted out onto the SDA pin after the falling edge of SCL is asserted (see data hold time spec). SCL is held low for one baud rate generator roll over count (T_{BRG}). Data should be valid before SCL is released high (see Data setup time spec). When the SCL pin is released high, it is held that way for T_{BRG} , the data on the SDA pin must remain stable for that duration and some hold time after the next falling edge of SCL. After the eighth bit is shifted out (the falling edge of the eighth clock), the BF flag is cleared and the master releases SDA allowing the slave device being addressed to respond with an \overline{ACK} bit during the ninth bit time, if an address match occurs or if data was received properly. The status of \overline{ACK} is read into the SSPCON2 register bit6 on the falling edge of the ninth clock. If the master receives an acknowledge, the acknowledge status bit (AKSTAT) is cleared. If not, the bit is set. After the ninth clock the SSPIF is set, and the master clock (baud rate generator) is suspended until the next data byte is loaded into the SSPBUF leaving SCL low and SDA unchanged. (Figure 15-29)

15.2.9.1 BF STATUS FLAG

In transmit mode, the BF bit (SSPSTAT<0>) is set when the CPU writes to SSPBUF and is cleared when all 8 bits are shifted out.

15.2.9.2 WCOL STATUS FLAG

If the user writes the SSPBUF when a transmit is already in progress (i.e. SSPSR is still shifting out a data byte), then WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

WCOL must be cleared in software.

15.2.9.3 AKSTAT STATUS FLAG

In transmit mode, the AKSTAT bit (SSPCON2<6>) is cleared when the slave has sent an acknowledge ($\overline{ACK} = 0$), and is set when the slave does not acknowledge ($\overline{ACK} = 1$). A slave sends an acknowledge when it has recognized its address (including a general call), or when the slave has properly received its data.

FIGURE 15-28: MASTER TRANSMIT FLOWCHART

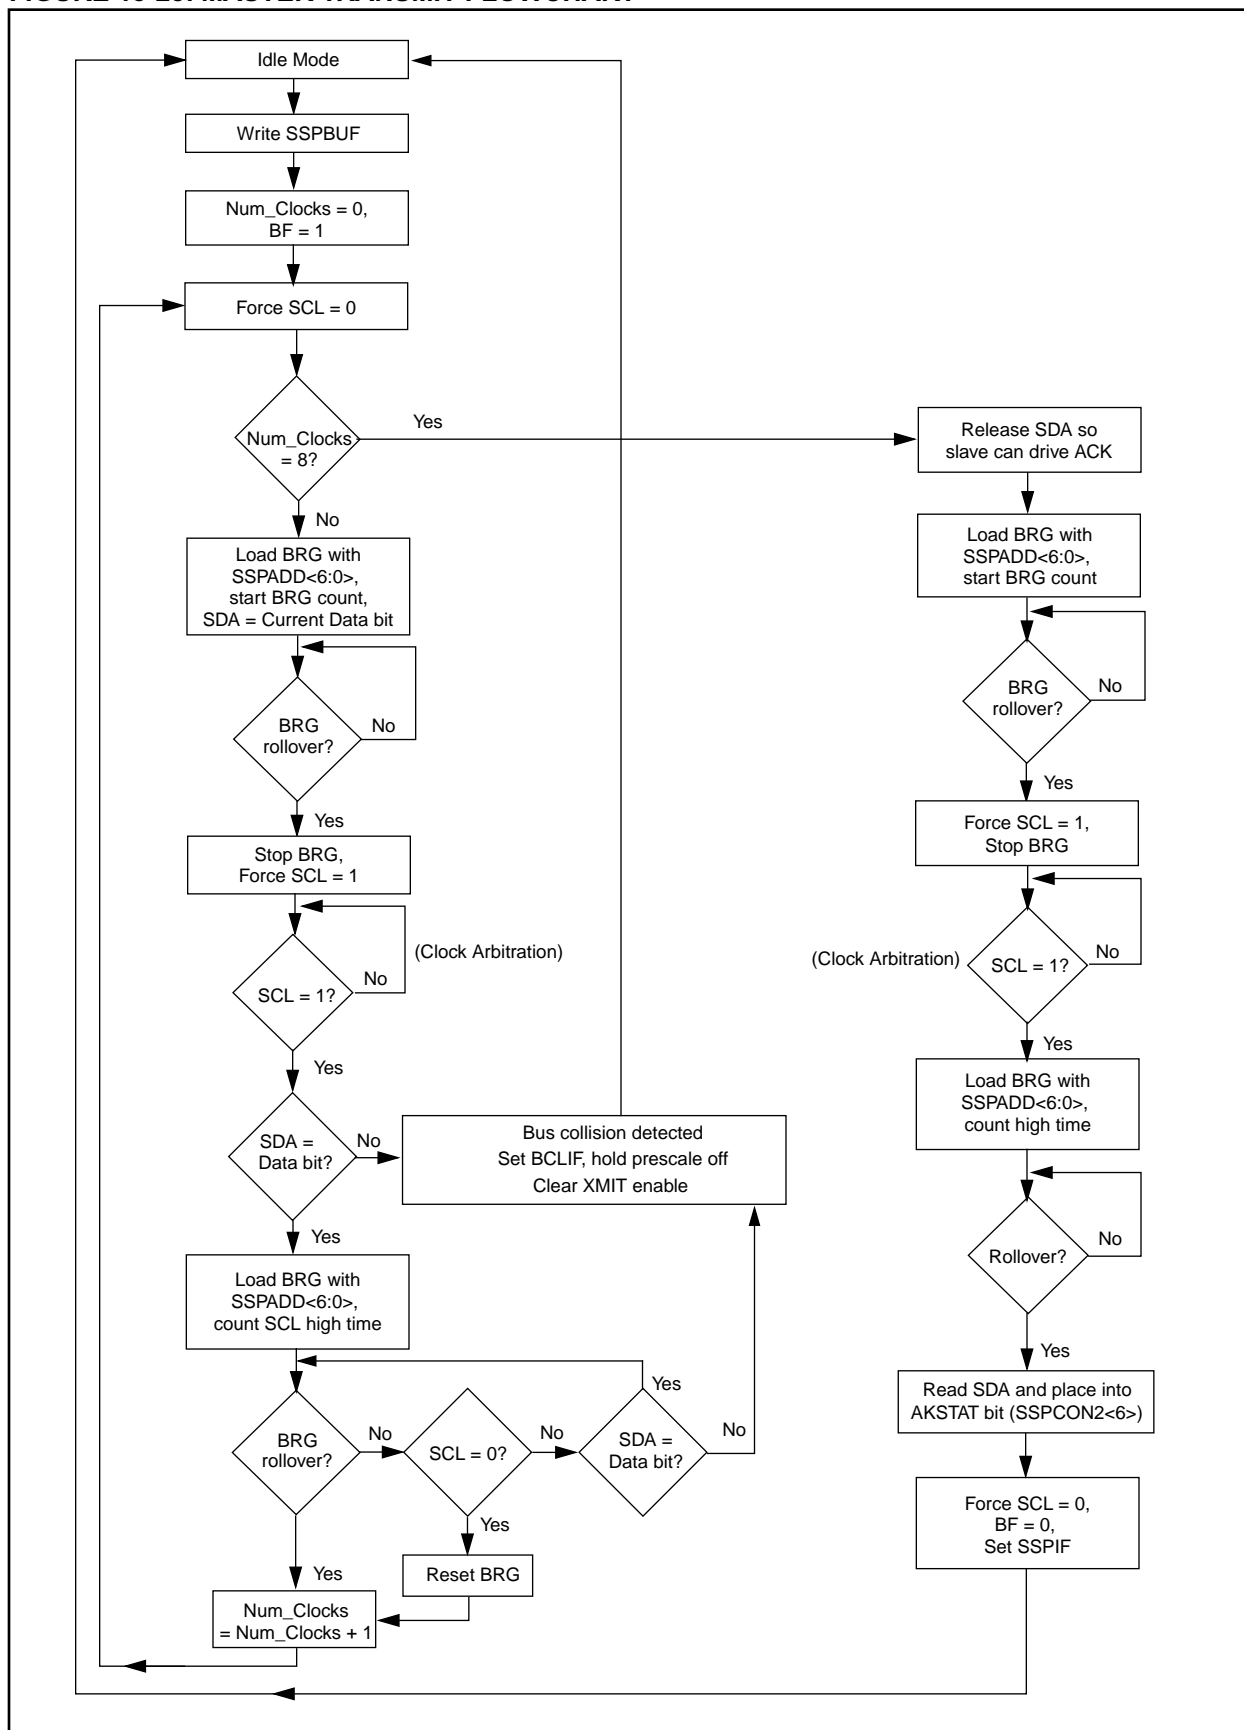

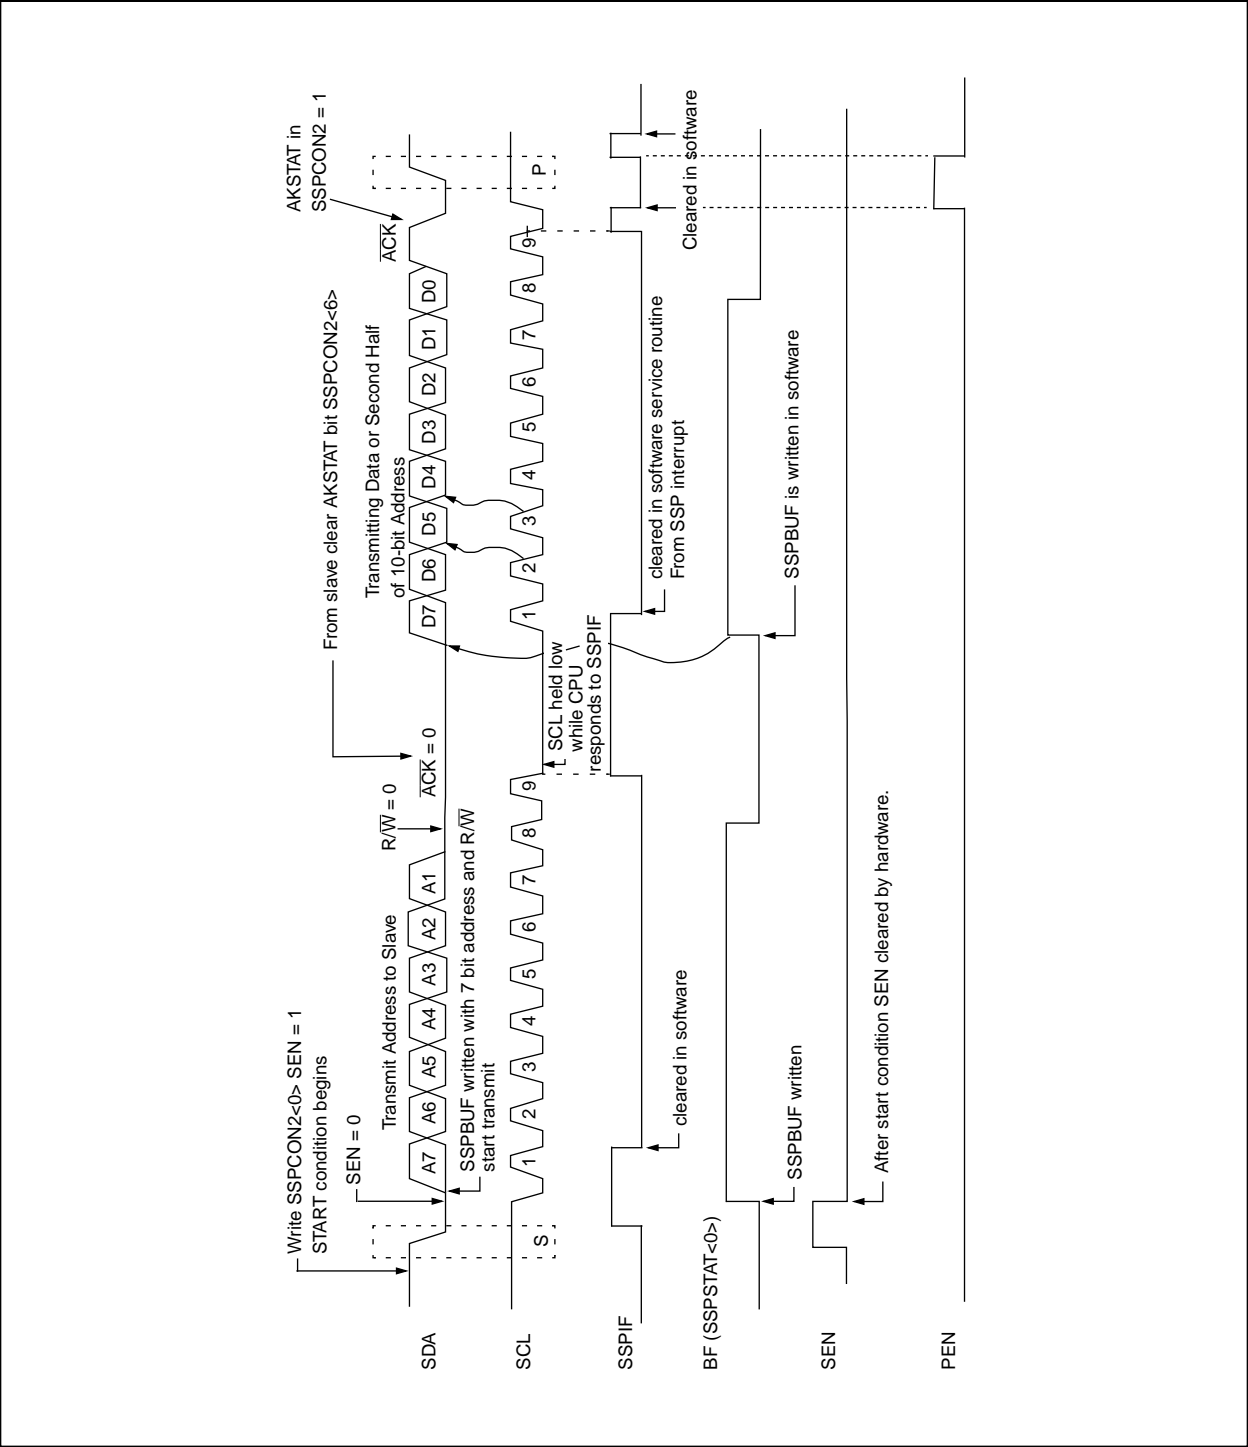

FIGURE 15-29: I²C MASTER MODE TIMING (TRANSMISSION, 7 OR 10-BIT ADDRESS)

15.2.10 I²C MASTER MODE RECEPTION

Master mode reception is enabled by programming the receive enable bit, RCEN (SSPCON2<3>).

Note: The SSP Module must be in IDLE mode before the RCE bit is set, or the RCEN bit will be disregarded.

The baud rate generator begins counting, and on each rollover, the state of the SCL pin changes (high to low/low to high), and data is shifted into the SSPSR. After the falling edge of the eighth clock, the receive enable flag is automatically cleared, the contents of the SSPSR are loaded into the SSPBUF, the BF flag is set, the SSPIF is set, and the baud rate generator is suspended from counting, holding SCL low. The SSP is now in IDLE state, awaiting the next command. When the buffer is read by the CPU, the BF flag is automatically cleared. The user can then send an acknowledge bit at the end of reception, by setting the acknowledge sequence enable bit, ACKEN (SSPCON2<4>).

15.2.10.1 BF STATUS FLAG

In receive operation, BF is set when an address or data byte is loaded into SSPBUF from SSPSR. It is cleared when SSPBUF is read.

15.2.10.2 SSPOV STATUS FLAG

In receive operation, SSPOV is set when 8 bits are received into the SSPSR, and the BF flag is already set from a previous reception.

15.2.10.3 WCOL STATUS FLAG

If the user writes the SSPBUF when a receive is already in progress (i.e. SSPSR is still shifting in a data byte), then WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

FIGURE 15-30: MASTER RECEIVER FLOWCHART

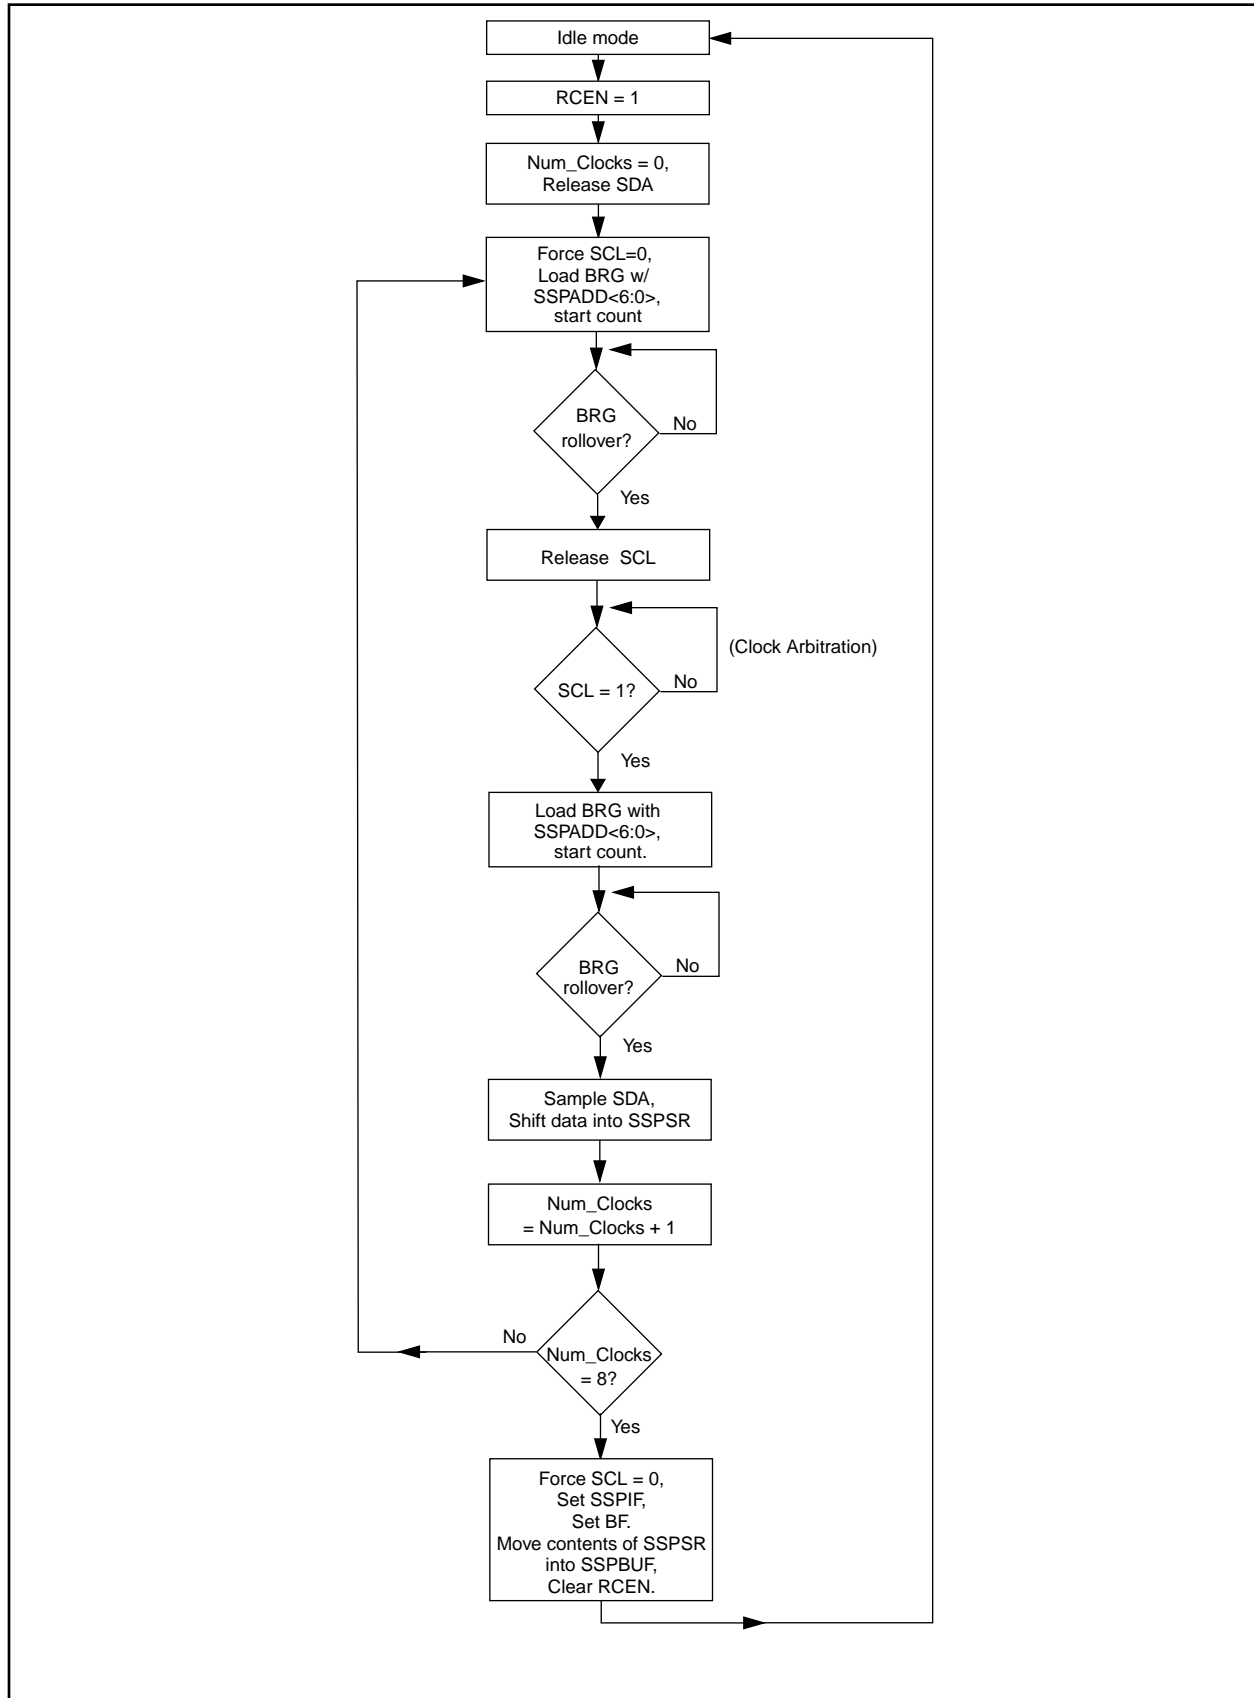

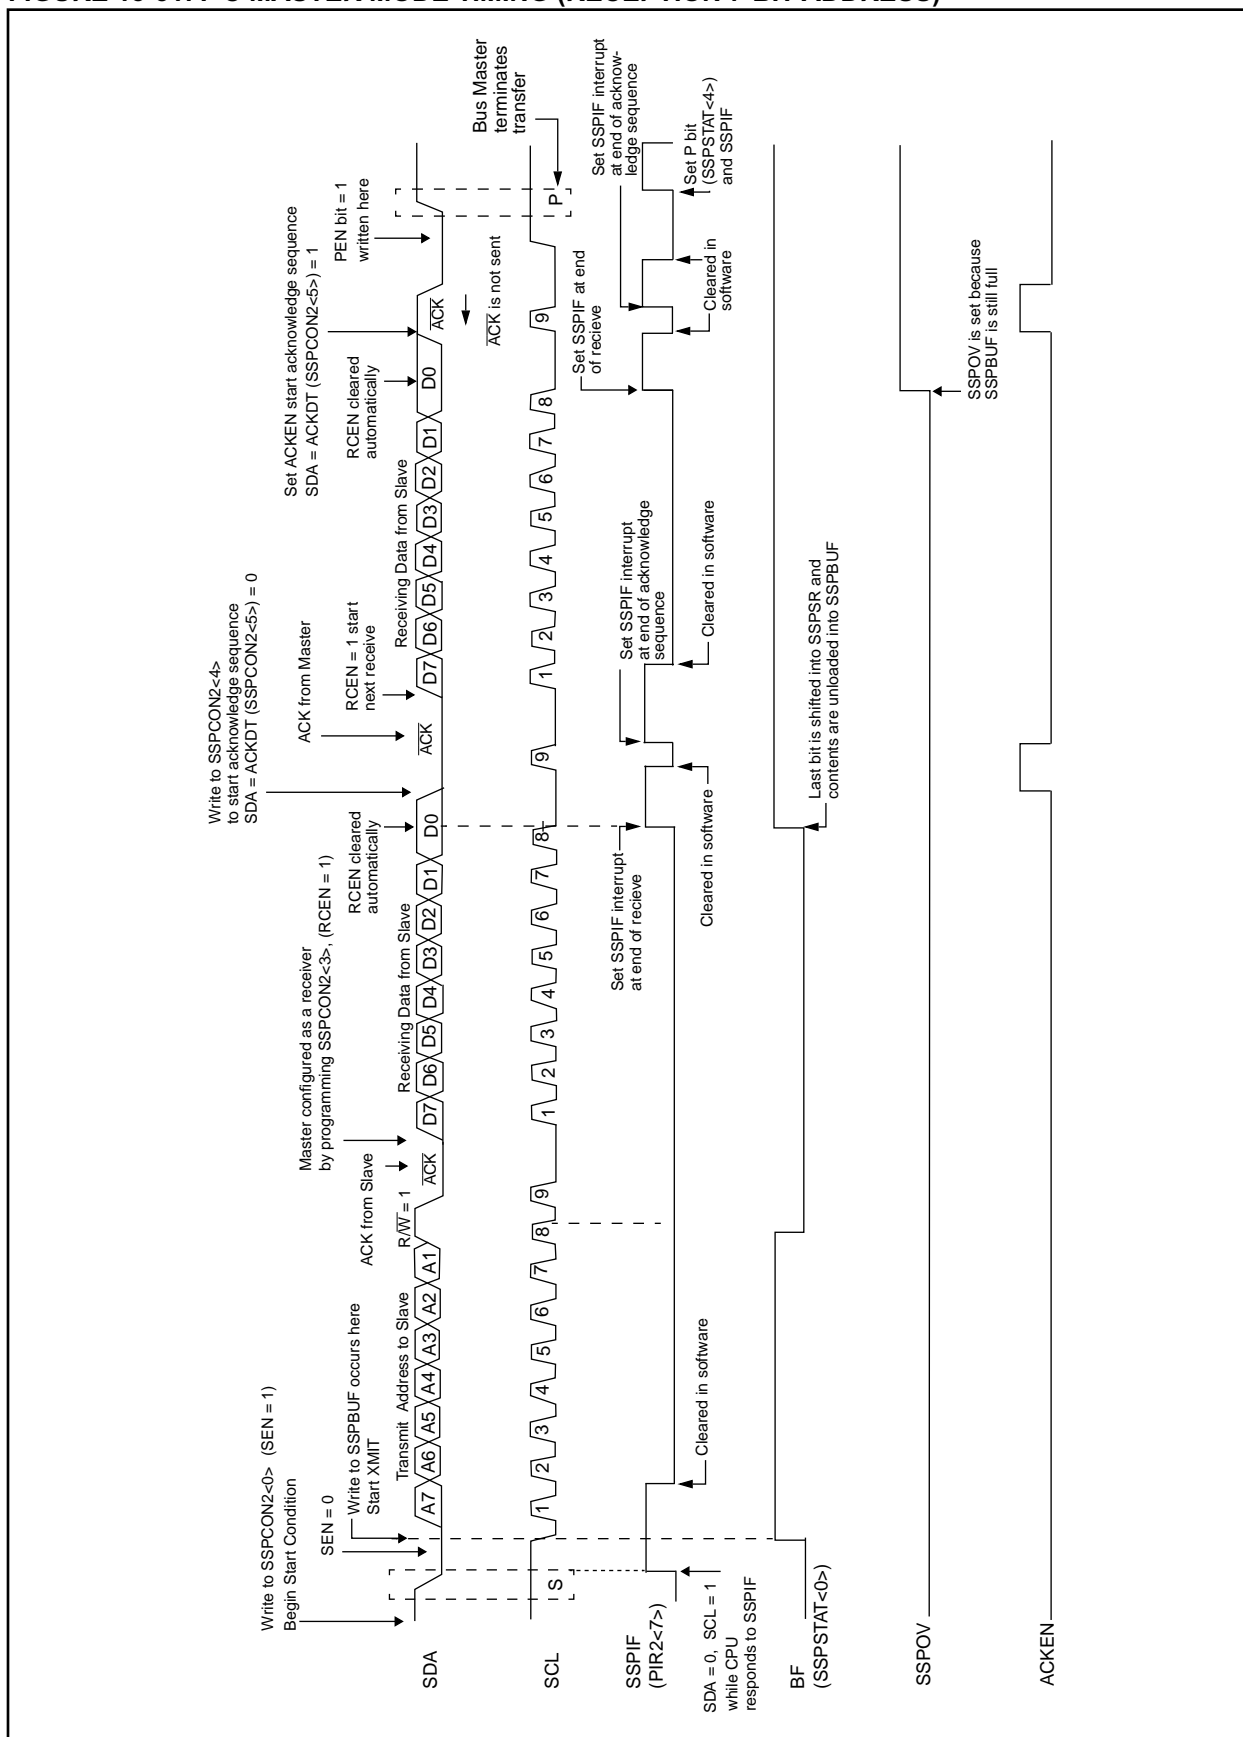

FIGURE 15-31: I²C MASTER MODE TIMING (RECEPTION 7-BIT ADDRESS)

15.2.11 ACKNOWLEDGE SEQUENCE TIMING

An acknowledge sequence is enabled by setting the acknowledge sequence enable bit, ACKEN (SSPCON2<4>). When this bit is set, the SCL pin is pulled low and the contents of the acknowledge data bit is presented on the SDA pin. If the user wishes to generate an acknowledge, then the ACKDT bit should be cleared. If not, the user should set the ACKDT bit before starting an acknowledge sequence. The baud rate generator then counts for one rollover period (T_{BRG}), and the SCL pin is de-asserted (pulled high). When the SCL pin is sampled high (clock arbitration), the baud rate generator counts for T_{BRG} . The SCL pin is then pulled low for one T_{BRG} . Following this, the ACKEN bit is automatically cleared, the baud rate generator is turned off, and the SSP module then goes into IDLE mode. (Figure 15-32)

15.2.11.1 WCOL STATUS FLAG

If the user writes the SSPBUF when an acknowledge sequence is in progress, then WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

FIGURE 15-32: ACKNOWLEDGE SEQUENCE TIMING

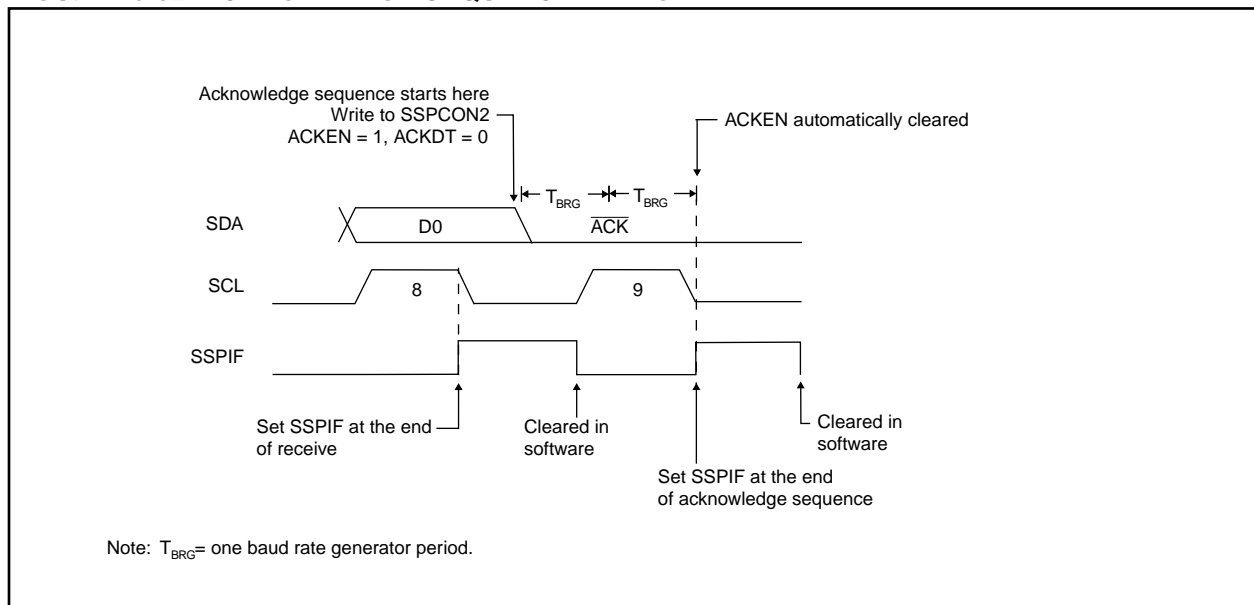

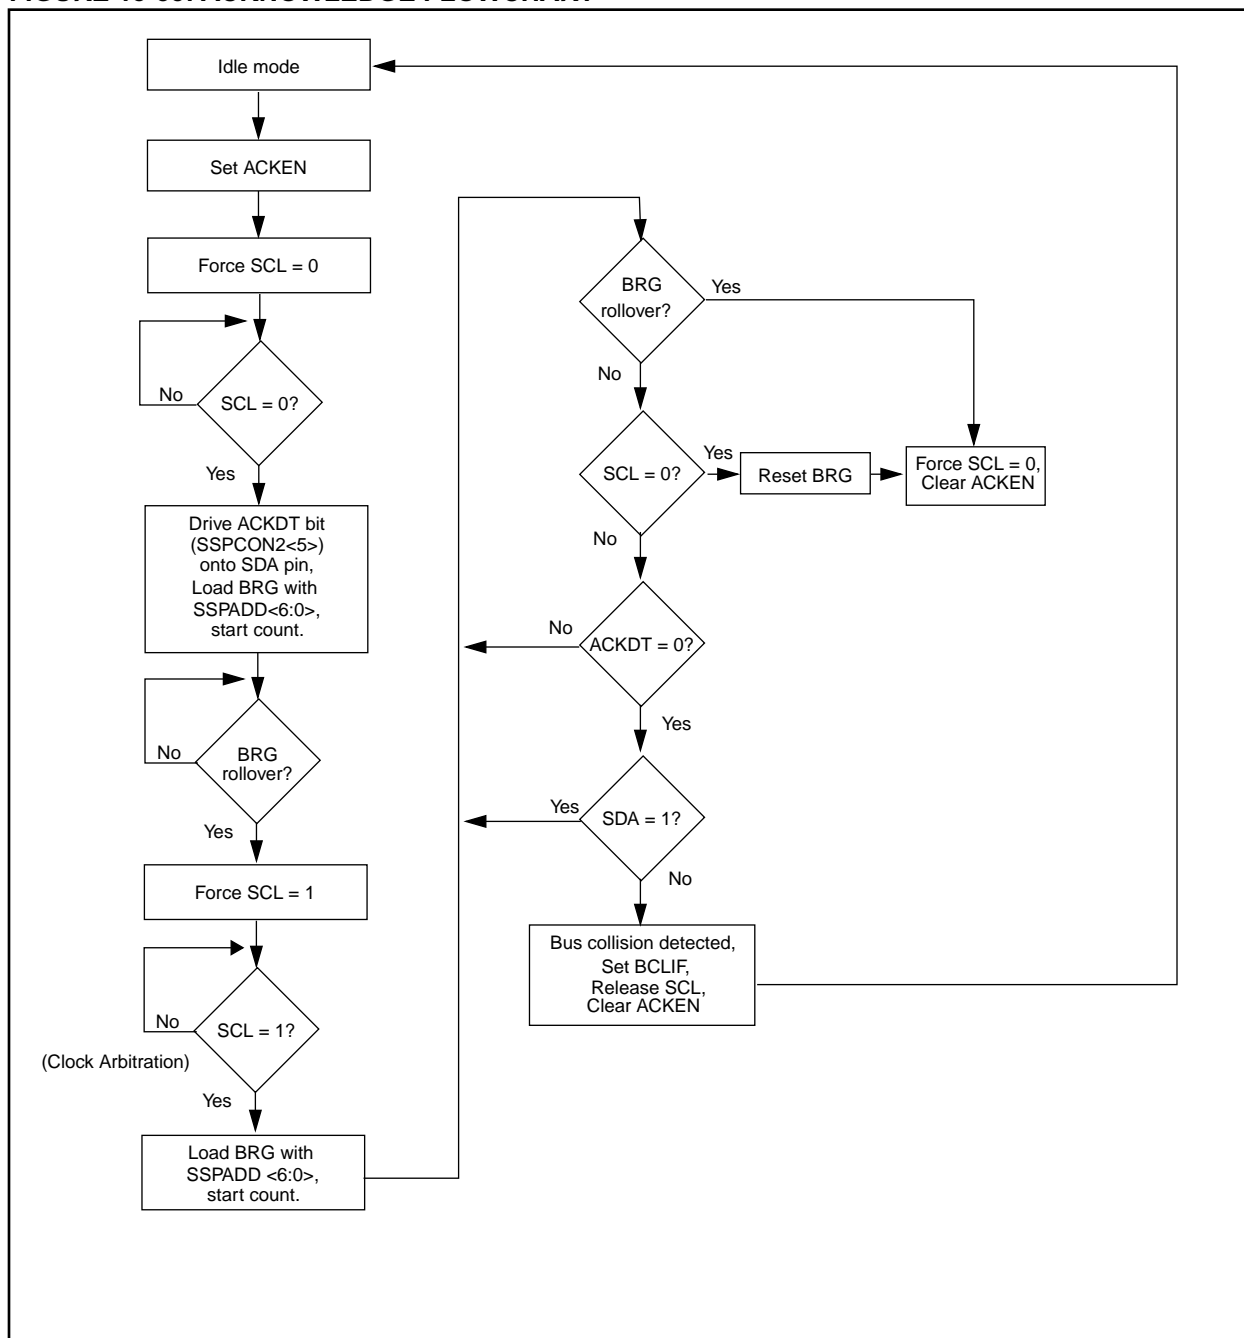

FIGURE 15-33: ACKNOWLEDGE FLOWCHART

15.2.12 STOP CONDITION TIMING

A stop bit is asserted on the SDA pin at the end of a receive/transmit by setting the Stop Sequence Enable bit PEN (SSPCON2<2>). At the end of a receive/transmit the SCL line is held low after the falling edge of the ninth clock. When the PEN bit is set, the master will assert the SDA line low. When the SDA line is sampled low, the baud rate generator is reloaded and counts down to 0. When the baud rate generator times out, the SCL pin will be brought high, and one T_{BRG} (baud rate generator rollover count) later, the SDA pin will be de-asserted. When the SDA pin is sampled high while SCL is high, the PEN bit will be automatically cleared, and the P bit (SSPSTAT<4>) is set which in turn will set the SSPIF flag. (Figure 15-34)

Whenever the CPU decides to take control of the bus, it will first determine if the bus is busy by checking the S and P bits in the SSPSTAT register. If the bus is busy, then the CPU can be interrupted (notified) when a Stop bit is detected (i.e. bus is free).

15.2.12.1 WCOL STATUS FLAG

If the user writes the SSPBUF when a STOP sequence is in progress, then WCOL is set and the contents of the buffer are unchanged (the write doesn't occur).

FIGURE 15-34: STOP CONDITION RECEIVE OR TRANSMIT MODE

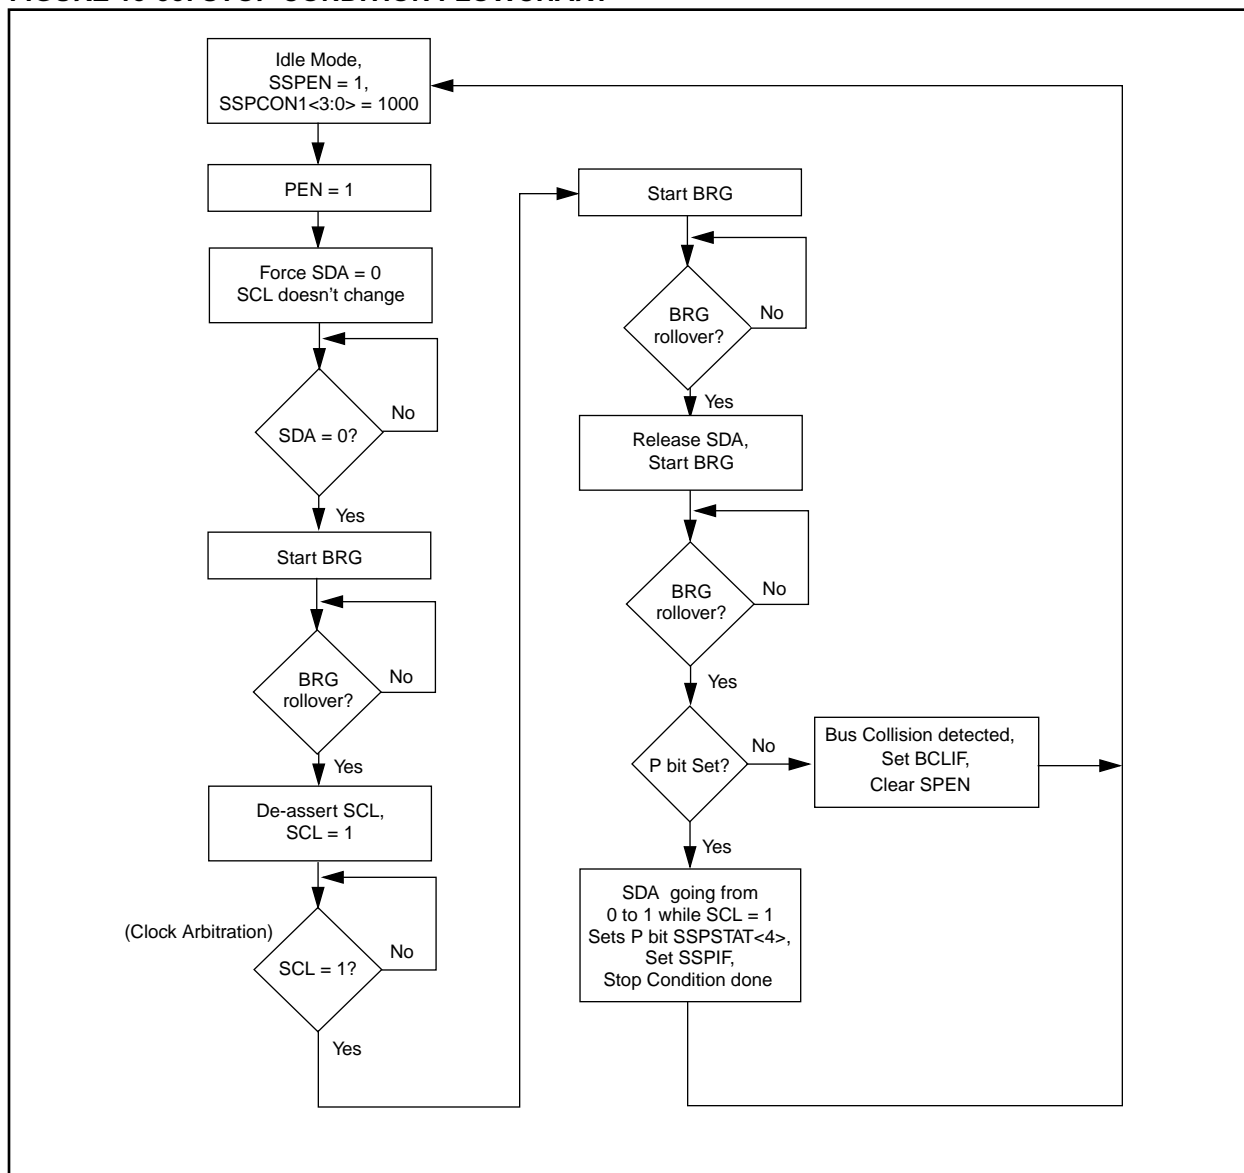

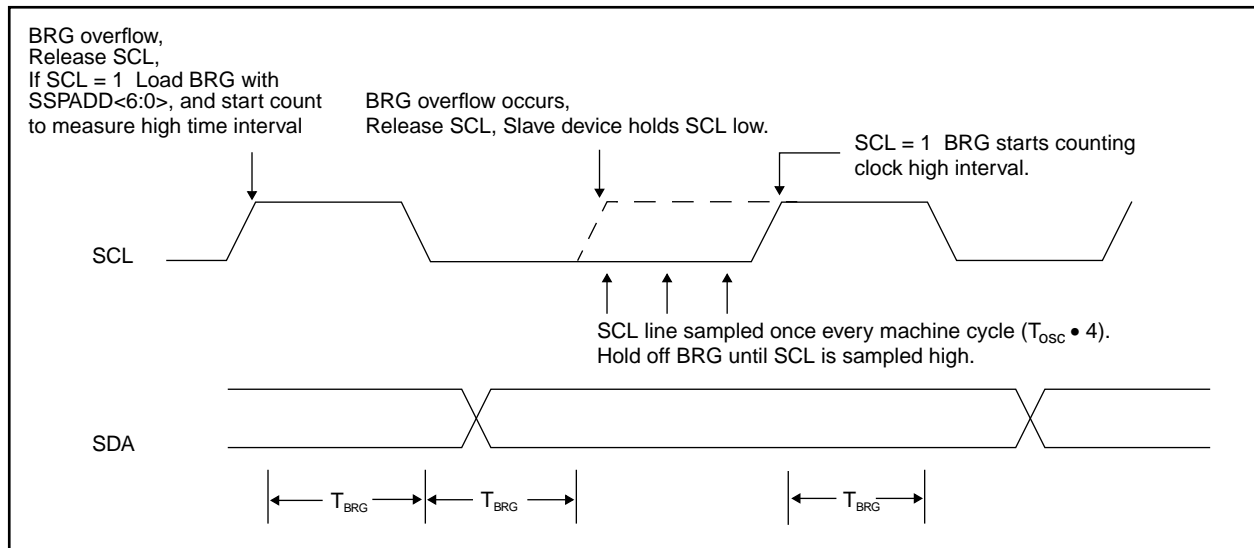

FIGURE 15-35: STOP CONDITION FLOWCHART

15.2.13 CLOCK ARBITRATION

Clock arbitration occurs when the master during any receive, transmit, or restart/stop condition de-asserts the SCL pin (SCL allowed to float high). When the SCL pin is allowed to float high, the baud rate generator (BRG) is suspended from counting until the SCL pin is actually sampled high. When the SCL pin is sampled high, the baud rate generator is reloaded with the contents of SSPADD<6:0> and begins counting. This ensures that the SCL high time will always be at least one BRG rollover count in the event that the clock is held low by an external device. (Figure 15-36)

FIGURE 15-36: CLOCK ARBITRATION TIMING IN MASTER TRANSMIT MODE

15.2.14 MULTI-MASTER COMMUNICATION, BUS COLLISION, AND BUS ARBITRATION

Multi-Master mode support is achieved by bus arbitration. When the master outputs address/data bits onto the SDA pin, arbitration takes place when the master outputs a '1' on SDA by letting SDA float high and another master asserts a '0'. When the SCL pin floats high, data should be stable. If the expected data on SDA is a '1' and the data sampled on the SDA pin = '0', then a bus collision has taken place. The master will set the Bus Collision Interrupt Flag, BCLIF and reset the I²C port to its IDLE state. (Figure 15-37).

If a transmit was in progress when the bus collision occurred, the transmission is halted, the BF flag is cleared, the SDA and SCL lines are de-asserted, and the SSPBUF can be written to. When the user services the bus collision interrupt service routine, and if the I²C bus is free, the user can resume communication by asserting a START condition.

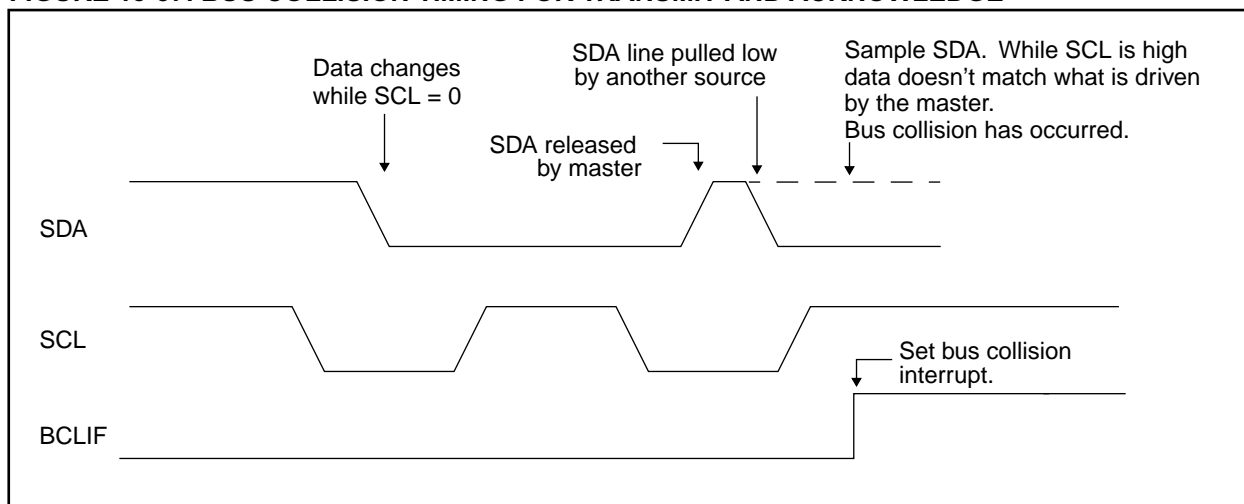

If a START, RESTART, STOP, or Acknowledge condition was in progress when the bus collision occurred, the condition is aborted, the SDA and SCL lines are de-asserted, and the respective control bits in the SSPCON2 register are cleared. When the user services the bus collision interrupt service routine, and if the I²C bus is free, the user can resume communication by asserting a START condition.

The Master will continue to monitor the SDA and SCL pins, and if a STOP condition occurs, the SSPIF bit will be set.

A write to the SSPBUF will start the transmission of data at the first data bit, regardless of where the transmitter left off when bus collision occurred.

In multi-master mode, the interrupt generation on the detection of start and stop conditions allows the determination of when the bus is free. Control of the I²C bus can be taken when the P bit is set in the SSPSTAT register, or the bus is idle and the S and P bits are cleared.

FIGURE 15-37: BUS COLLISION TIMING FOR TRANSMIT AND ACKNOWLEDGE

15.2.14.1 BUS COLLISION DURING A START CONDITION

During a START condition, a bus collision occurs if:

- SDA or SCL are sampled low at the beginning of the START condition (Figure 15-38)
- SCL is sampled low before SDA is asserted low. (Figure 15-39)

During a START condition both the SDA and the SCL pins are monitored.

If:

the SDA pin is already low
or the SCL pin is already low,

then:

the START condition is aborted,
and the BCLIF flag is set,
and the SSP module is reset to its IDLE state
(Figure 15-38).

The START condition begins with the SDA and SCL pins de-asserted. When the SDA pin is sampled high, the baud rate generator is loaded from SSPADD<6:0> and counts down to 0. If the SCL pin is sampled low while SDA is high, a bus collision occurs, because it is assumed that another master is attempting to drive a data '1' during the START condition.

If the SDA pin is sampled low during this count, the BRG is reset and the SDA line is asserted early (Figure 15-40). If however a '1' is sampled on the SDA pin, the SDA pin is asserted low at the end of the BRG count. The baud rate generator is then reloaded and counts down to 0, and during this time, if the SCL pins is sampled as '0', a bus collision does not occur. At the end of the BRG count the SCL pin is asserted low.

Note: The reason that bus collision is not a factor during a START condition is that no two bus masters can assert a START condition at the exact same time. Therefore, one master will always assert SDA before the other. This condition does not cause a bus collision because the two masters must be allowed to arbitrate the first address following the START condition, and if the address is the same, arbitration must be allowed to continue into the data portion, RESTART, or STOP conditions.

FIGURE 15-38: BUS COLLISION DURING START CONDITION (SDA ONLY)

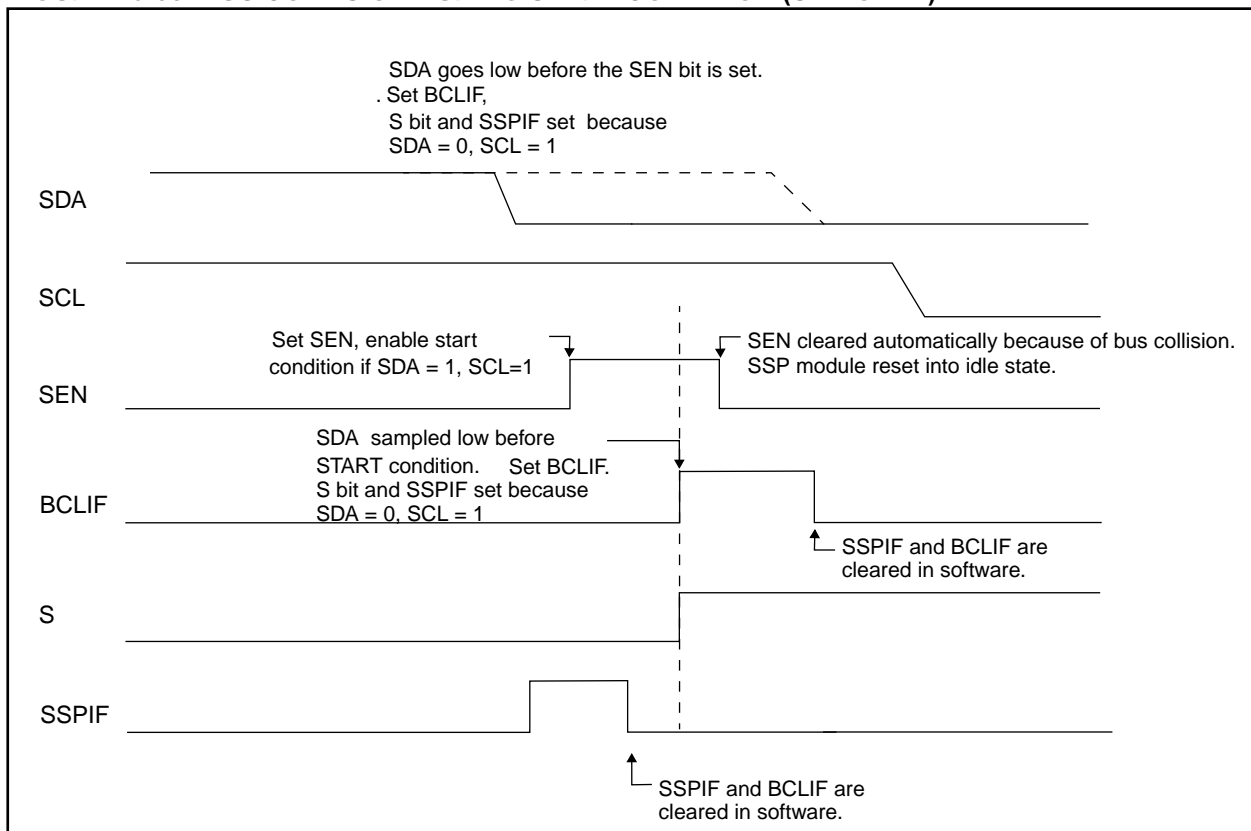

FIGURE 15-39: BUS COLLISION DURING START CONDITION (SCL = 0)

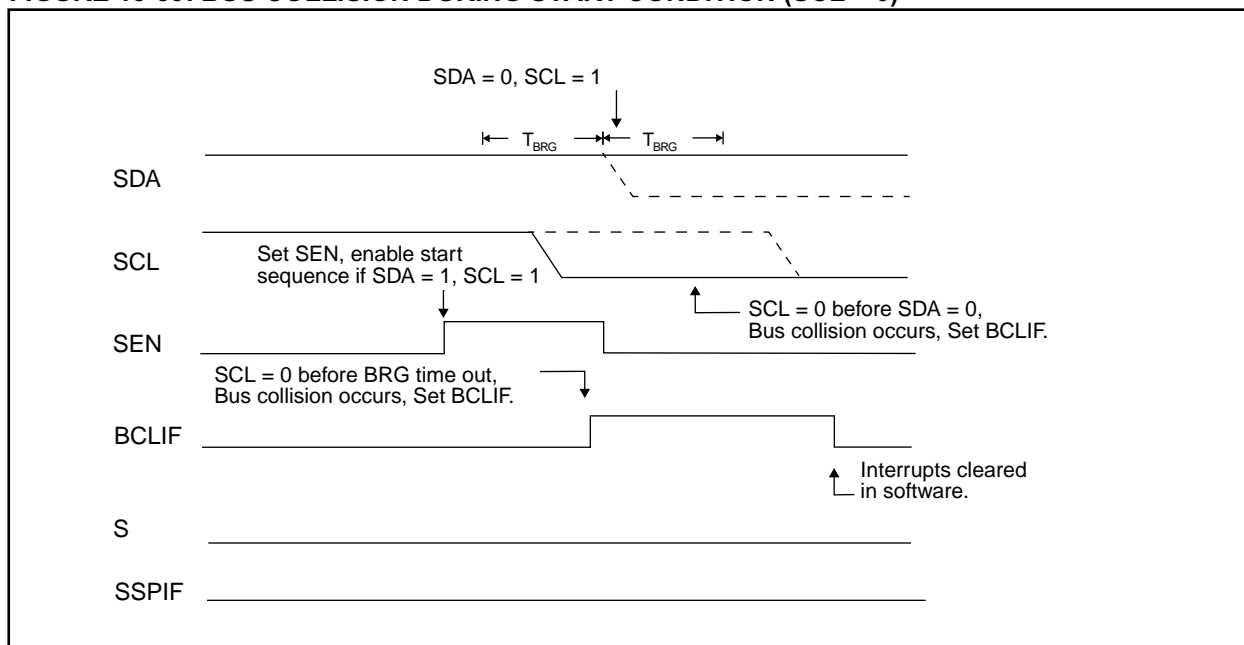

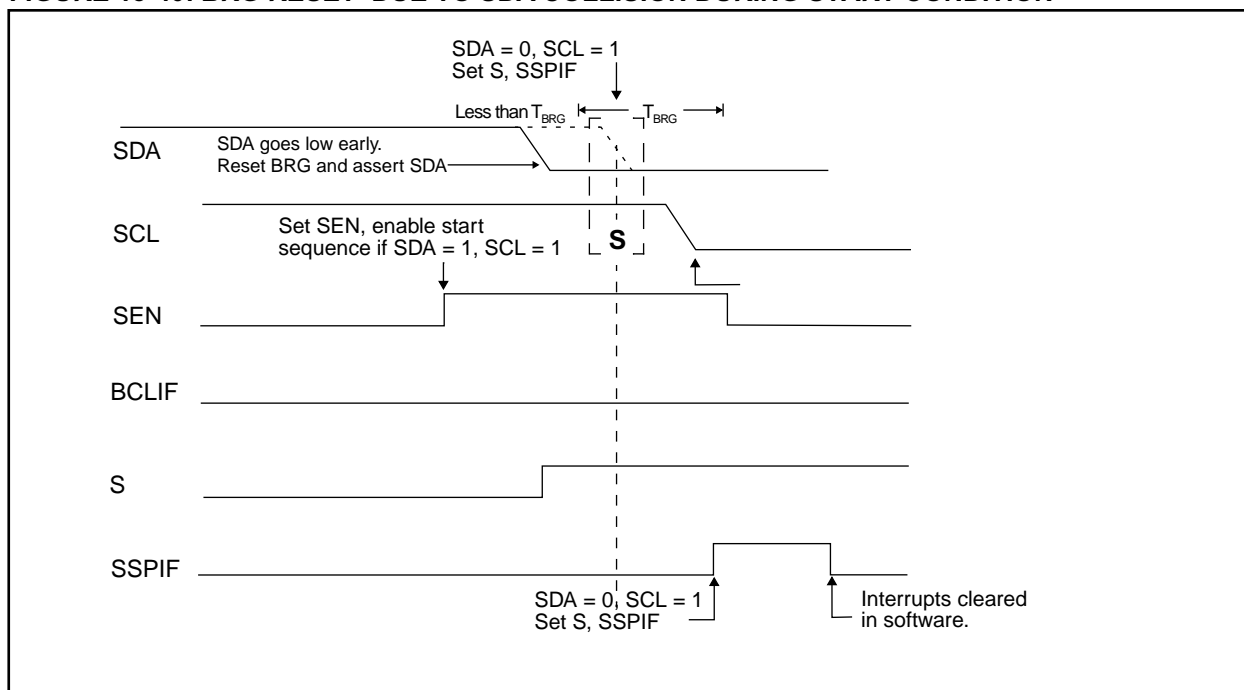

FIGURE 15-40: BRG RESET DUE TO SDA COLLISION DURING START CONDITION

15.2.14.2 BUS COLLISION DURING A RESTART CONDITION

During a RESTART condition, a bus collision occurs if:

- A '0' is sampled on SDA when SCL goes from '0' to '1'
- SCL goes low before SDA is asserted low, indicating that another master is attempting to transmit a data '1'.

When the user de-asserts SDA and the pin is allowed to float high, the BRG is loaded with SSPADD<6:0>, and counts down to 0. The SCL pin is then de-asserted, and when sampled high, the SDA pin is sampled. If SDA is low, a bus collision has occurred (i.e. another master is attempting to transmit a data '0'). If however SDA is sampled high then the BRG is

reloaded and begins counting. If SDA goes from high to low before the BRG times out, no bus collision occurs, because no two masters can assert SDA at exactly the same time.

If, however, SCL goes from high to low before the BRG times out and SDA has not already been asserted, then a bus collision occurs. In this case, another master is attempting to transmit a data '1' during the RESTART condition.

If at the end of the BRG time out both SCL and SDA are still high, the SDA pin is driven low, the BRG is reloaded, and begins counting. At the end of the count, regardless of the status of the SCL pin, the SCL pin is driven low and the RESTART condition is complete. (Figure 15-41)

FIGURE 15-41: BUS COLLISION DURING A RESTART CONDITION (CASE 1)

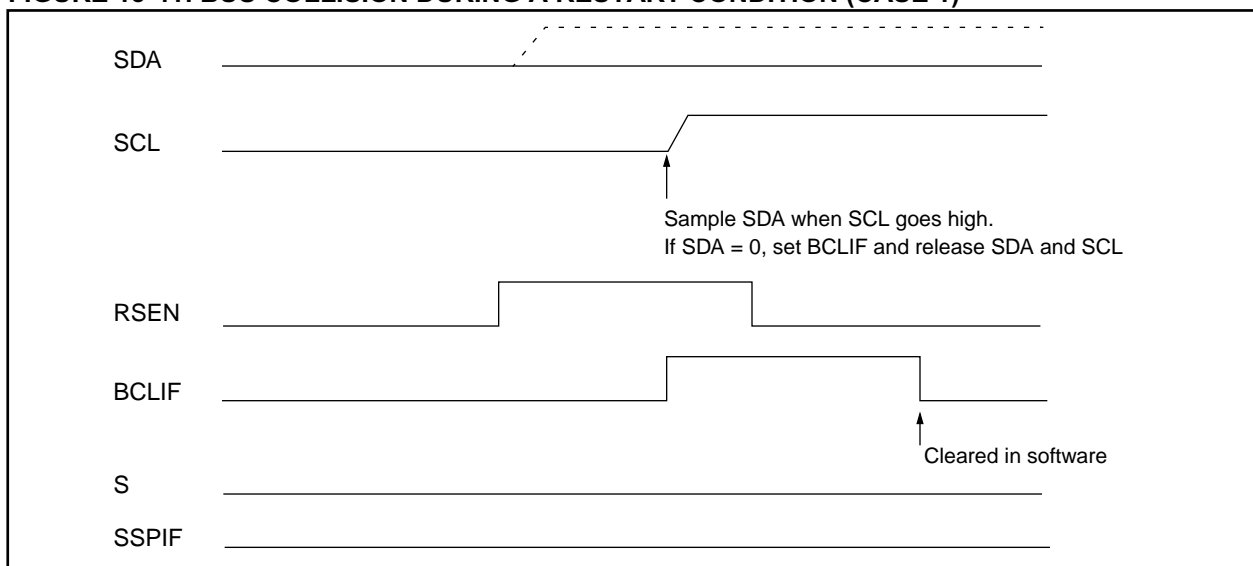

FIGURE 15-42: BUS COLLISION DURING RESTART CONDITION (CASE 2)

15.2.14.3 BUS COLLISION DURING A STOP CONDITION

Bus collision occurs during a STOP condition if:

- After the SDA pin has been de-asserted and allowed to float high, SDA is sampled low after the BRG has timed out.
- After the SCL pin is de-asserted, SCL is sampled low before SDA goes high.

The STOP condition begins with SDA asserted low. When SDA is sampled low, the SCL pin is allowed to float. When the pin is sampled high (clock arbitration), the baud rate generator is loaded with SSPADD<6:0> and counts down to 0. After the BRG times out SDA is sampled. If SDA is sampled low, a bus collision has occurred. This is due to another master attempting to drive a data '0'. If the SCL pin is sampled low before SDA is allowed to float high, a bus collision occurs. This is another case of another master attempting to drive a data '0'. (Figure 15-43)

FIGURE 15-43: BUS COLLISION DURING A STOP CONDITION (CASE 1)

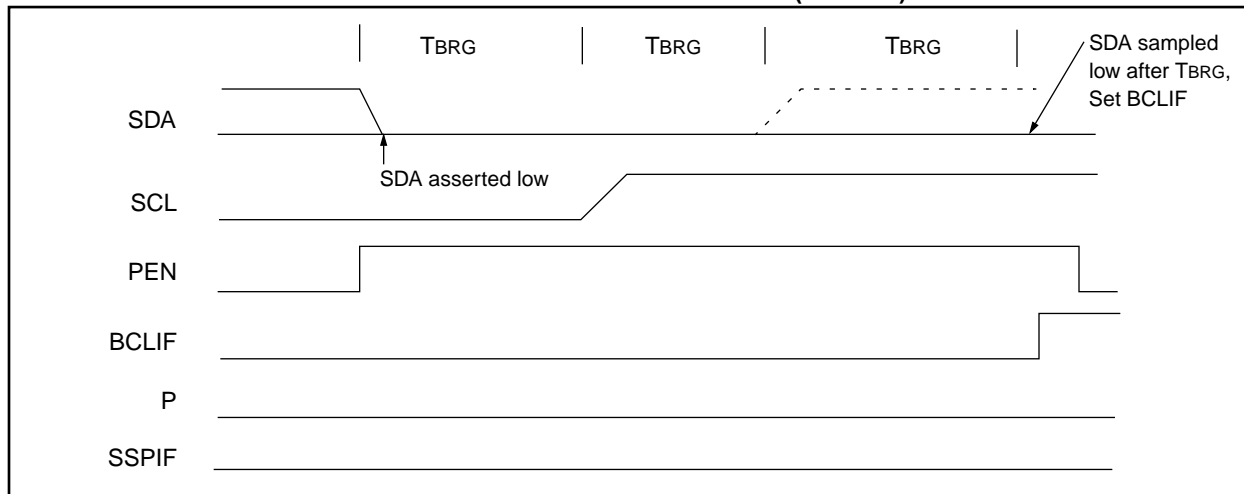

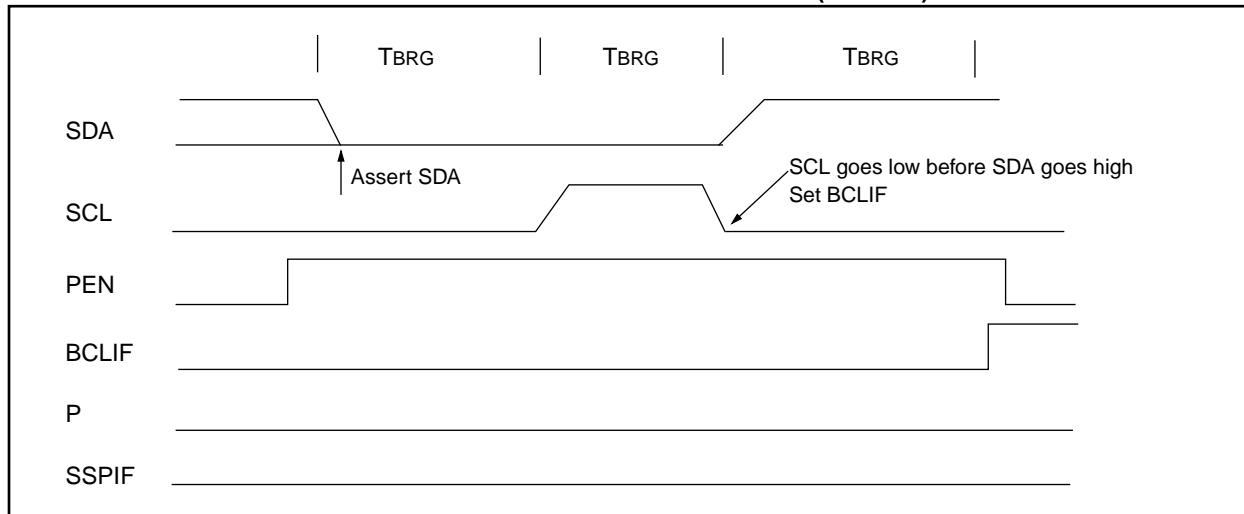

FIGURE 15-44: BUS COLLISION DURING A STOP CONDITION (CASE 2)

15.3 Connection Considerations for I²C Bus

For standard-mode I²C bus devices, the values of resistors R_p R_s in Figure 15-45 depends on the following parameters

- Supply voltage
- Bus capacitance
- Number of connected devices (input current + leakage current).

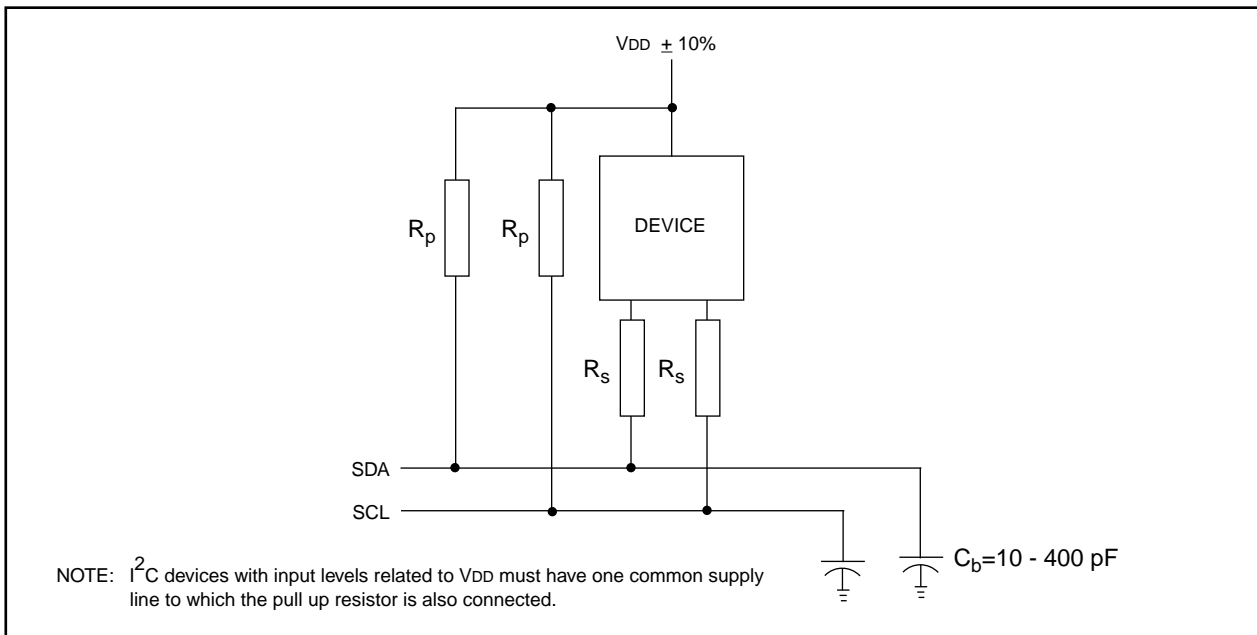

The supply voltage limits the minimum value of resistor R_p due to the specified minimum sink current of 3 mA at $V_{OL\ max} = 0.4V$ for the specified output stages. For example, with a supply voltage of $V_{DD} = 5V \pm 10\%$ and $V_{OL\ max} = 0.4V$ at 3 mA, $R_{p\ min} = (5.5 - 0.4) / 0.003 = 1.7\ k\Omega$. V_{DD} as a function of R_p is shown in Figure 15-45. The desired noise margin of $0.1V_{DD}$ for the low level, limits the maximum value of R_s . Series resistors are optional.

The bus capacitance is the total capacitance of wire, connections, and pins. This capacitance limits the maximum value of R_p due to the specified rise time (Figure 15-45).

The SMP bit is the slew rate control enabled bit. This bit is in the SSPSTAT register, and controls the slew rate of the I/O pins when in I²C mode (master or slave).

This control ensures that the rise and fall times of the SCL and SDA pins will meet the minimum requirements as specified in the I²C specification for 400 kHz operation.

FIGURE 15-45: SAMPLE DEVICE CONFIGURATION FOR I²C BUS

NOTES:

16.0 ANALOG-TO-DIGITAL CONVERTER (A/D) MODULE

The analog-to-digital (A/D) converter module has twelve analog inputs for the PIC17C75X devices.

The A/D allows conversion of an analog input signal to a corresponding 10-bit digital number. The output of the sample and hold is the input into the converter, which generates the result via successive approximation.

The analog reference voltages (positive and negative supply) are software selectable to either the device's supply voltages (AVDD, AVSS) or the voltage level on the RG3/AN0/VREF+ and RG2/AN1/VREF- pins.

The A/D converter has a unique feature of being able to operate while the device is in SLEEP mode. To operate in sleep, the A/D clock must be derived from the A/D's internal RC oscillator.

The A/D module has four registers. These registers are:

- A/D Result High Register (ADRESH)
- A/D Result Low Register (ADRESL)
- A/D Control Register0 (ADCON0)
- A/D Control Register1 (ADCON1)

The ADCON0 register, shown in Figure 16-1, controls the operation of the A/D module. The ADCON1 register, shown in Figure 16-2, configures the functions of the port pins. The port pins can be configured as analog inputs (RG3 and RG2 can also be the voltage references) or as digital I/O.

A = Analog input D = Digital I/O

bit 0: **PCFG0:** A/D Voltage Reference Select bit
1 = A/D reference is the VREF+ and VREF- pins
0 = A/D reference is AVDD and AVSS

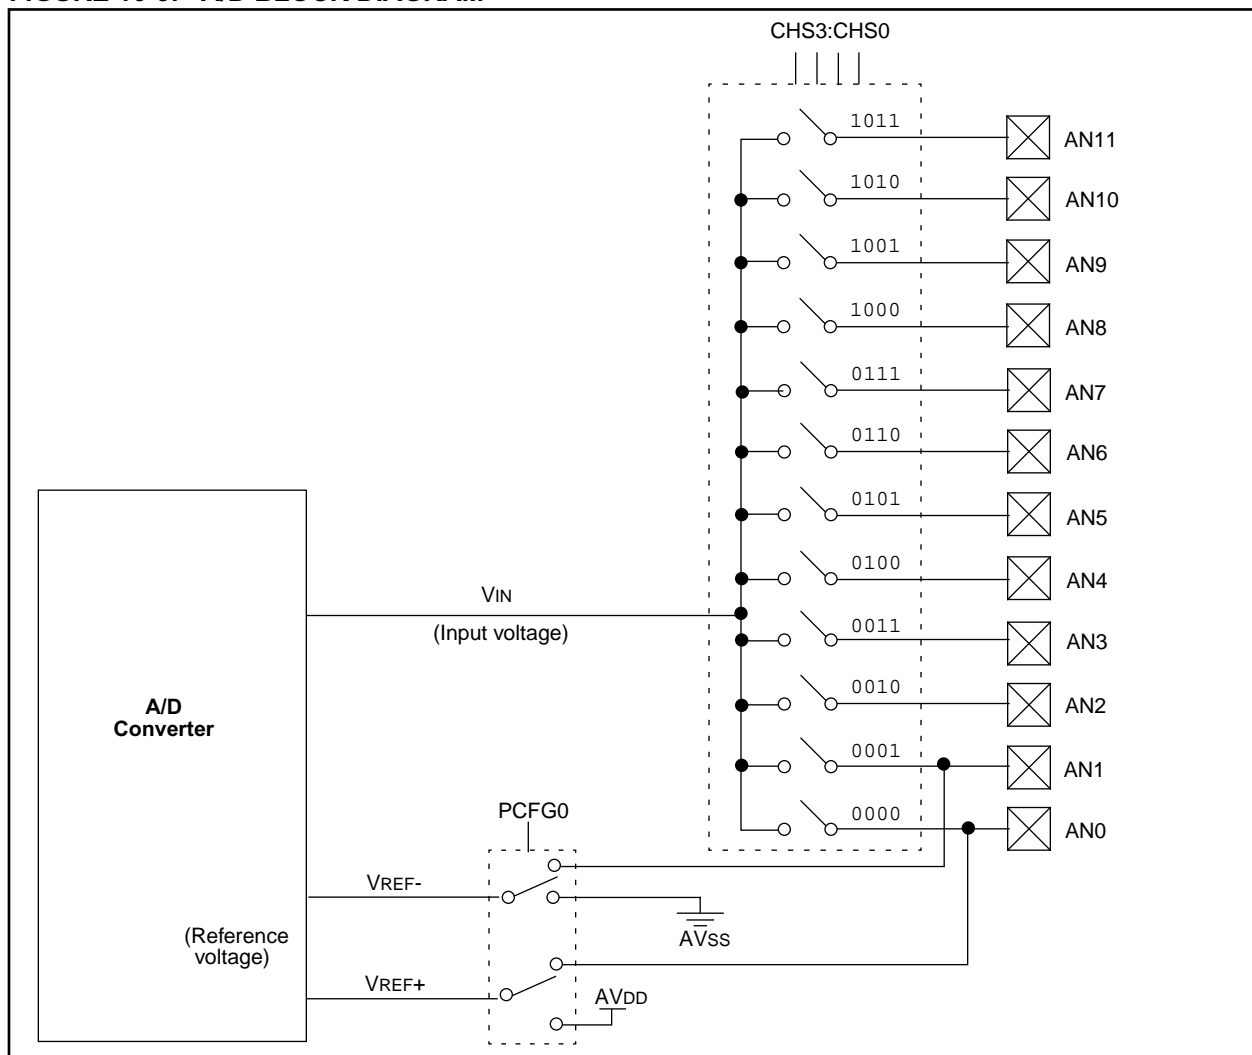

Note:When this bit is set, ensure that the A/D voltage reference specifications are met.

The ADRESH:ADRESL registers contains the 10-bit result of the A/D conversion. When the A/D conversion is complete, the result is loaded into this A/D result register pair, the GO/DONE bit (ADCON0<2>) is cleared, and A/D interrupt flag bit ADIF is set. The block diagrams of the A/D module are shown in Figure 16-3.

After the A/D module has been configured as desired, the selected channel must be acquired before the conversion is started. The analog input channels must have their corresponding DDR bits selected as inputs. To determine acquisition time, see Section 16.1. After this acquisition time has elapsed the A/D conversion can be started. The following steps should be followed for doing an A/D conversion:

1. Configure the A/D module:
 - Configure analog pins / voltage reference / and digital I/O (ADCON1)
 - Select A/D input channel (ADCON0)
 - Select A/D conversion clock (ADCON0)
 - Turn on A/D module (ADCON0)
2. Configure A/D interrupt (if desired):
 - Clear ADIF bit
 - Set ADIE bit
 - Clear GLINTD bit
3. Wait the required acquisition time.
4. Start conversion:
 - Set GO/DONE bit (ADCON0)
5. Wait for A/D conversion to complete, by either:
 - Polling for the GO/DONE bit to be cleared
 OR
 - Waiting for the A/D interrupt
6. Read A/D Result register pair (ADRESH:ADRESL), clear bit ADIF if required.
7. For next conversion, go to step 1 or step 2 as required. The A/D conversion time per bit is defined as TAD. A minimum wait of 2TAD is required before next acquisition starts.

FIGURE 16-3: A/D BLOCK DIAGRAM

16.1 A/D Acquisition Requirements

For the A/D converter to meet its specified accuracy, the charge holding capacitor (CHOLD) must be allowed to fully charge to the input channel voltage level. The analog input model is shown in Figure 16-4. The source impedance (R_s) and the internal sampling switch (R_{ss}) impedance directly affect the time required to charge the capacitor CHOLD. The sampling switch (R_{ss}) impedance varies over the device voltage (V_{DD}), Figure 16-4. The source impedance affects the offset voltage at the analog input (due to pin leakage current).

The maximum recommended impedance for analog sources is 10 k Ω . After the analog input channel is selected (changed) this acquisition must be done before the conversion can be started.

To calculate the minimum acquisition time, Equation 16-1 may be used. This equation calculates the acquisition time to within 1/2 LSB error (1024 steps for the A/D). The 1/2 LSB error is the maximum error allowed for the A/D to meet its specified accuracy.

EQUATION 16-1: A/D MINIMUM CHARGING TIME (FOR CHOLD)

$$V_{HOLD} = (V_{REF} - (V_{REF}/2048)) \cdot (1 - e^{-(T_{cap}/CHOLD)(R_{IC} + R_{SS} + R_s)})$$

given $V_{HOLD} = (V_{REF}/2048)$, for 1/2 LSB resolution

$$V_{REF} = V_{REF+} - V_{REF-}$$

or

$$T_{cap} = -(200 \text{ pF})(1 \text{ k}\Omega + R_{SS} + R_s) \ln(1/2047)$$

Example 16-1 shows the calculation of the minimum required acquisition time T_{ACQ} . This calculation is based on the following application system assumptions.

$$CHOLD = 200 \text{ pF}$$

$$R_s = 10 \text{ k}\Omega$$

$$1/2 \text{ LSB error}$$

$$V_{DD} = 5V \rightarrow R_{ss} = 7 \text{ k}\Omega$$

$$\text{Temp (application system max.)} = 50^\circ\text{C}$$

$$V_{HOLD} = 0 \text{ @ } t = 0$$

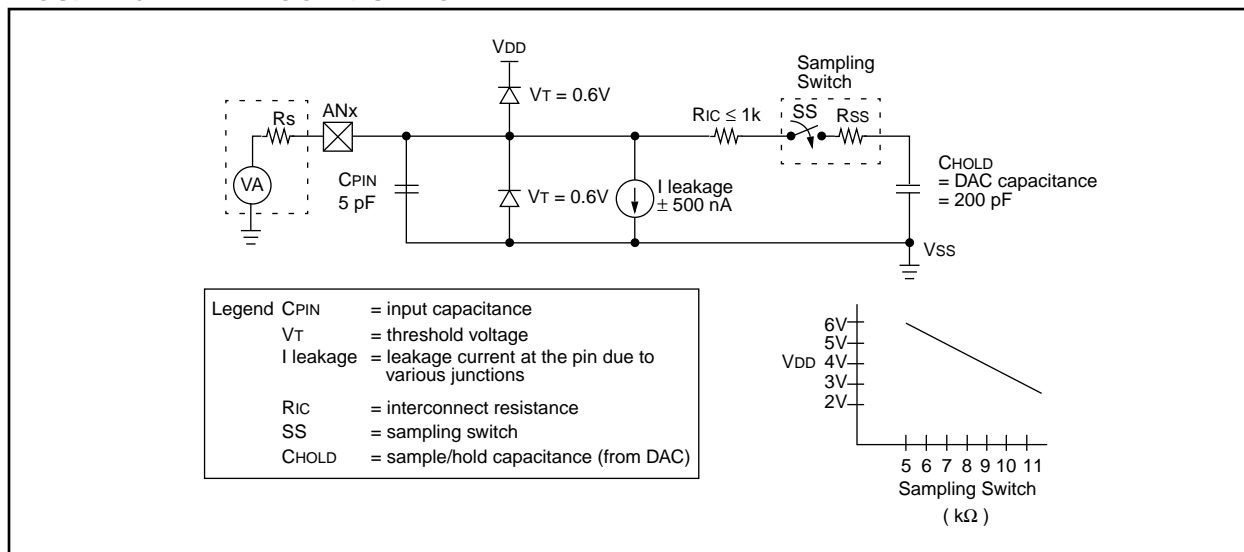

Note 1: The reference voltage (V_{REF}) has no effect on the equation, since it cancels itself out.

Note 2: The charge holding capacitor (CHOLD) is not discharged after each conversion.

Note 3: The maximum recommended impedance for analog sources is 10 k Ω . This is required to meet the pin leakage specification.

Note 4: After a conversion has completed, a 2.0TAD delay must complete before acquisition can begin again. During this time the holding capacitor is not connected to the selected A/D input channel.

FIGURE 16-4: ANALOG INPUT MODEL

EXAMPLE 16-1: CALCULATING THE MINIMUM REQUIRED ACQUISITION TIME

$T_{ACQ} = \text{Amplifier Settling Time} +$
 $\text{Holding Capacitor Charging Time} +$
 $\text{Temperature Coefficient } \uparrow$

\uparrow Only required for temperatures $\neq 25^{\circ}\text{C}$

$T_{ACQ} = 10 \mu\text{s} + T_{cap} + [(\text{Temp} - 25^{\circ}\text{C})(0.05 \mu\text{s}/^{\circ}\text{C})]$

$T_{CAP} = -\text{CHOLD} (\text{R}_{IC} + \text{R}_{SS} + \text{R}_S) \ln(1/2047)$
 $-200 \text{ pF} (1 \text{ k}\Omega + 7 \text{ k}\Omega + 10 \text{ k}\Omega) \ln(0.0004885)$
 $-200 \text{ pF} (18 \text{ k}\Omega) \ln(0.0004885)$
 $-3.6 \mu\text{s} (-7.6241)$
 $27.447 \mu\text{s}$

$T_{ACQ} = 10 \mu\text{s} + 27.447 \mu\text{s} + [(50^{\circ}\text{C} - 25^{\circ}\text{C})(0.05 \mu\text{s}/^{\circ}\text{C})]$
 $37.447 \mu\text{s} + 1.25 \mu\text{s}$
 $38.697 \mu\text{s}$

16.2 Selecting the A/D Conversion Clock

The A/D conversion time per bit is defined as T_{AD} . The A/D conversion requires a minimum $12T_{AD}$ per 10-bit conversion. The source of the A/D conversion clock is software selected. The four possible options for T_{AD} are:

- $8T_{OSC}$
- $32T_{OSC}$
- $64T_{OSC}$
- Internal RC oscillator

For correct A/D conversions, the A/D conversion clock (T_{AD}) must be selected to ensure a minimum T_{AD} time of $1.6 \mu\text{s}$.

Table 16-1 and Table 16-2 show the resultant T_{AD} times derived from the device operating frequencies and the A/D clock source selected. These times are for standard voltage range devices.

TABLE 16-1: T_{AD} vs. DEVICE OPERATING FREQUENCIES (STANDARD DEVICES (C))

AD Clock Source (T_{AD})		Device Frequency				
Operation	ADCS1:ADCS0	33 MHz	20 MHz	5 MHz	1.25 MHz	333.33 kHz
8TOSC	00	242 ns ⁽²⁾	400 ns ⁽²⁾	1.6 μs	6.4 μs	24 μs
32TOSC	01	970 ns ⁽²⁾	1.6 μs	6.4 μs	25.6 μs ⁽³⁾	96 μs ⁽³⁾
64TOSC	10	1.94 μs	3.2 μs	12.8 μs ⁽³⁾	51.2 μs ⁽³⁾	192 μs ⁽³⁾
RC	11	2 - 6 μs ^(1, 4)	2 - 6 μs ^(1, 4)	2 - 6 μs ^(1, 4)	2 - 6 μs ^(1, 4)	2 - 6 μs ⁽¹⁾

Legend: Shaded cells are outside of recommended ranges.

Note 1: The RC source has a typical T_{AD} time of 4 μs .

2: These values violate the minimum required T_{AD} time.

3: For faster conversion times, the selection of another clock source is recommended.

4: When the device frequencies is greater than 1 MHz, the RC A/D conversion clock source is only recommended for sleep operation.

TABLE 16-2: T_{AD} vs. DEVICE OPERATING FREQUENCIES (EXTENDED VOLTAGE DEVICES (LC))

AD Clock Source (T_{AD})		Device Frequency				
Operation	ADCS1:ADCS0	8 MHz	4 MHz	2 MHz	1 MHz	333.33 kHz
8TOSC	00	1.0 μs ⁽²⁾	2.0 μs ⁽²⁾	4 μs	8 μs	24 μs
32TOSC	01	4.0 μs	8 μs	16 μs	32 μs ⁽³⁾	96 μs ⁽³⁾
64TOSC	10	8.0 μs	16 μs	32 μs ⁽³⁾	64 μs ⁽³⁾	192 μs ⁽³⁾
RC	11	3 - 9 μs ^(1, 4)	3 - 9 μs ^(1, 4)	3 - 9 μs ^(1, 4)	3 - 9 μs ⁽¹⁾	3 - 9 μs ⁽¹⁾

Legend: Shaded cells are outside of recommended ranges.

Note 1: The RC source has a typical T_{AD} time of 4 μs .

2: These values violate the minimum required T_{AD} time.

3: For faster conversion times, the selection of another clock source is recommended.

4: When the device frequencies is greater than 1 MHz, the RC A/D conversion clock source is only recommended for sleep operation.

16.3 Configuring Analog Port Pins

The ADCON1, and DDR registers control the operation of the A/D port pins. The port pins that are desired as analog inputs must have their corresponding DDR bits set (input). If the DDR bit is cleared (output), the digital output level (VOH or VOL) will be converted.

The A/D operation is independent of the state of the CHS2:CHS0 bits and the DDR bits.

Note 1: When reading the port register, any pin configured as an analog input channel will read as cleared (a low level). Pins configured as digital inputs, will convert an analog input. Analog levels on a digitally configured input will not affect the conversion accuracy.

Note 2: Analog levels on any pin that is defined as a digital input (including the AN11:AN0 pins), may cause the input buffer to consume current that is out of the devices specification.

16.4 A/D Conversions

Example 16-2 shows how to perform an A/D conversion. The PORTF and lower four PORTG pins are configured as analog inputs. The analog references (VREF+ and VREF-) are the device AVDD and AVSS. The A/D interrupt is enabled, and the A/D conversion clock is FRC. The conversion is performed on the RG3/AN0 pin (channel 0).

Note: The GO/DONE bit should **NOT** be set in the same instruction that turns on the A/D.

Clearing the GO/DONE bit during a conversion will abort the current conversion. The A/D result register pair will NOT be updated with the partially completed A/D conversion sample. That is, the ADRESH:ADRESL registers will continue to contain the value of the last completed conversion (or the last value written to the ADRESH:ADRESL registers). After the A/D conversion is aborted, a 2TAD wait is required before the next acquisition is started. After this 2TAD wait, acquisition on the selected channel is automatically started.

EXAMPLE 16-2: A/D CONVERSION

```

    :                ; is cleared upon completion of the A/D Conversion

```

16.4.1 A/D RESULT REGISTERS

The ADRESH:ADRESL register pair is the location where the 10-bit A/D result is loaded at the completion of the A/D conversion. This register pair is 16-bits wide. The A/D module gives the flexibility to left or right justify the 10-bit result in the 16-bit result register. The A/D Format Select bit (ADFM) controls this justification. Figure 16-5 shows the operation of the A/D result justification. The extra bits are loaded with '0's'. When an A/D result will not overwrite these locations (A/D disable), these registers may be used as two general purpose 8-bit registers.

16.5 A/D Operation During Sleep

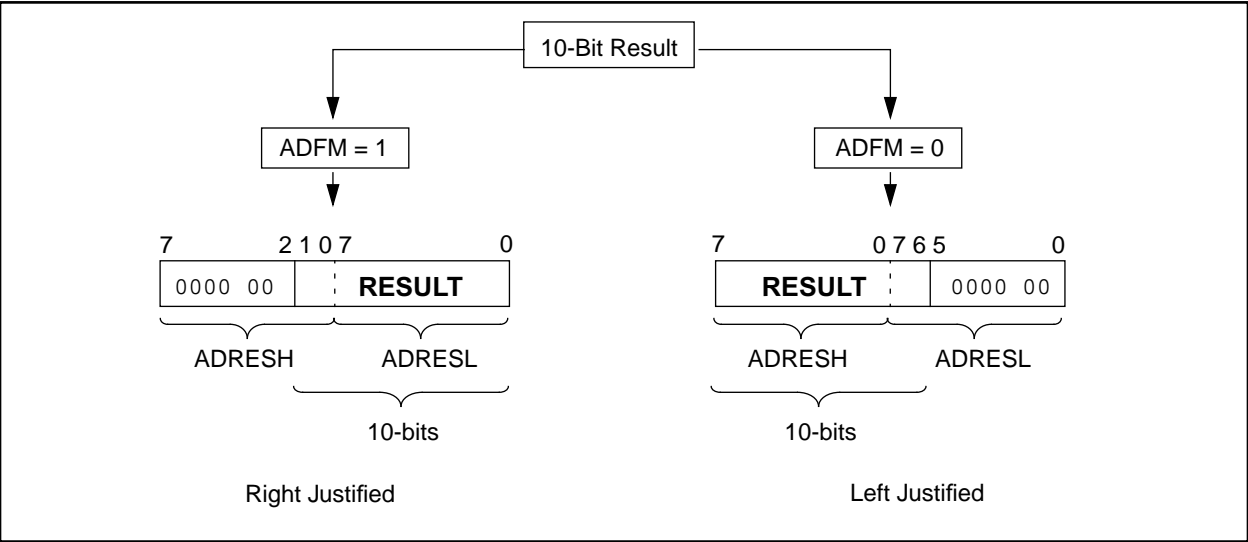

The A/D module can operate during SLEEP mode. This requires that the A/D clock source be set to RC (ADCS1:ADCS0 = 11). When the RC clock source is selected, the A/D module waits one instruction cycle before starting the conversion. This allows the SLEEP instruction to be executed, which eliminates all digital switching noise from the conversion. When the conversion is completed the GO/DONE bit will be cleared, and the result loaded into the ADRES register. If the A/D interrupt is enabled, the device will wake-up from SLEEP. If the A/D interrupt is not enabled, the A/D module will then be turned off, although the ADON bit will remain set.

When the A/D clock source is another clock option (not RC), a SLEEP instruction will cause the present conversion to be aborted and the A/D module to be turned off, though the ADON bit will remain set.

Turning off the A/D places the A/D module in its lowest current consumption state.

Note: For the A/D module to operate in SLEEP, the A/D clock source must be set to RC (ADCS1:ADCS0 = 11). To allow the conversion to occur during SLEEP, ensure the SLEEP instruction immediately follows the instruction that sets the GO/DONE bit.

FIGURE 16-5: A/D RESULT JUSTIFICATION

16.6 A/D Accuracy/Error

The absolute accuracy specified for the A/D converter includes the sum of all contributions for quantization error, integral error, differential error, full scale error, offset error, and monotonicity. It is defined as the maximum deviation from of an actual transition versus an ideal transition for any code. The absolute error of the A/D converter is specified at $< \pm 1$ LSB for $V_{DD} = V_{REF}$ (over the device's specified operating range). However, the accuracy of the A/D converter will degrade as V_{DD} diverges from V_{REF} .

For a given range of analog inputs, the output digital code will be the same. This is due to the quantization of the analog input to a digital code. Quantization error is typically $\pm 1/2$ LSB and is inherent in the analog to digital conversion process. The only way to reduce quantization error is to increase the resolution of the A/D converter.

Offset error measures the first actual transition of a code versus the first ideal transition of a code. Offset error shifts the entire transfer function. Offset error can be calibrated out of a system or introduced into a system through the interaction of the total leakage current and source impedance at the analog input.

Gain error measures the maximum deviation of the last actual transition and the last ideal transition adjusted for offset error. This error appears as a change in slope of the transfer function. The difference is gain error to full scale error is that full scale does not take offset error into account. Gain error can be calibrated out in software.

Linearity error refers to the uniformity of the code changes. Linearity errors cannot be calibrated out of the system. Integral non-linearity error measures the actual code transition versus the ideal code transition adjusted by the gain error for each code.

Differential non-linearity measures the maximum actual code width versus the ideal code width. This measure is unadjusted.

The maximum pin leakage current is $\pm 1 \mu A$.

In systems where the device frequency is low, use of the A/D RC clock is preferred. At moderate to high frequencies, T_{AD} should be derived from the device oscillator. T_{AD} must not violate the minimum and should be $\leq 8 \mu s$ for preferred operation. This is because T_{AD} , when derived from T_{OSC} , is kept away from on-chip phase clock transitions. This reduces, to a large extent, the effects of digital switching noise. This is not possible with the RC derived clock. The loss of accuracy due to digital switching noise can be significant if many I/O pins are active.

In systems where the device will enter SLEEP mode after the start of the A/D conversion, the RC clock source selection is required. In this mode, the digital noise from the modules in SLEEP are stopped. This method gives high accuracy.

16.7 Effects of a Reset

A device reset forces all registers to their reset state. This forces the A/D module to be turned off, and any conversion is aborted.

The value that is in the ADRESH:ADRESL registers is not modified for a Power-on Reset. The ADRESH:ADRESL registers will contain unknown data after a Power-on Reset.

16.8 Connection Considerations

If the input voltage exceeds the rail values (V_{SS} or V_{DD}) by greater than 0.3V, then the accuracy of the conversion is out of specification.

An external RC filter is sometimes added for anti-aliasing of the input signal. The R component should be selected to ensure that the total source impedance is kept under the 10 k Ω recommended specification. Any external components connected (via hi-impedance) to an analog input pin (capacitor, zener diode, etc.) should have very little leakage current at the pin.

16.9 Transfer Function

The transfer function of the A/D converter is as follows: the first transition occurs when the analog input voltage (V_{AIN}) equals Analog $V_{REF} / 1024$ (Figure 16-6).

FIGURE 16-6: A/D TRANSFER FUNCTION

16.10 References

A good reference for the understanding A/D converter is the "Analog-Digital Conversion Handbook" third edition, published by Prentice Hall (ISBN 0-13-03-2848-0).

PIC17C75X

NOTES:

17.0 SPECIAL FEATURES OF THE CPU

What sets a microcontroller apart from other processors are special circuits to deal with the needs of real-time applications. The PIC17CXXX family has a host of such features intended to maximize system reliability, minimize cost through elimination of external components, provide power saving operating modes and offer code protection. These are:

- Oscillator selection (Section 4.0)
- Reset (Section 5.0)
 - Power-on Reset (POR)
 - Power-up Timer (PWRT)
 - Oscillator Start-up Timer (OST)
 - Brown-out Reset (BOR)
- Interrupts (Section 6.0)
- Watchdog Timer (WDT)
- SLEEP mode
- Code protection

The PIC17CXXX has a Watchdog Timer which can be shutoff only through EPROM bits. It runs off its own RC oscillator for added reliability. There are two timers that offer necessary delays on power-up. One is the Oscillator Start-up Timer (OST), intended to keep the chip in RESET until the crystal oscillator is stable. The other is the Power-up Timer (PWRT), which provides a fixed delay of 96 ms (nominal) on power-up only, designed to keep the part in RESET while the power supply stabilizes. With these two timers on-chip, most applications need no external reset circuitry.

The SLEEP mode is designed to offer a very low current power-down mode. The user can wake from SLEEP through external reset, Watchdog Timer Reset or through an interrupt. Several oscillator options are also made available to allow the part to fit the application. The RC oscillator option saves system cost while the LF crystal option saves power. Configuration bits are used to select various options. This configuration word has the format shown in Figure 17-1.

17.1 Configuration Bits

The PIC17CXXX has eight configuration locations (Table 17-1). These locations can be programmed (read as '0') or left unprogrammed (read as '1') to select various device configurations. Any write to a configuration location, regardless of the data, will program that configuration bit. A `TABLWT` instruction is required to write to program memory locations. The configuration bits can be read by using the `TABLRD` instructions. Reading any configuration location between FE00h and FE07h will read the low byte of the configuration word (Figure 17-1) into the TABLATL register. The TABLATH register will be FFh. Reading a configuration location between FE08h and FE0Fh will read the high byte of the configuration word into the TABLATL register. The TABLATH register will be FFh.

Addresses FE00h through FE0Fh are only in the program memory space for microcontroller and code protected microcontroller modes. A device programmer will be able to read the configuration word in any processor mode. See programming specifications for more detail.

TABLE 17-1: CONFIGURATION LOCATIONS

Bit	Address
FOSC0	FE00h
FOSC1	FE01h
WDTPS0	FE02h
WDTPS1	FE03h
PM0	FE04h
PM1	FE06h
BODEN	FE0Eh
PM2	FE0Fh

Note: When programming the desired configuration locations, they must be programmed in ascending order. Starting with address FE00h.

17.2 Oscillator Configurations

17.2.1 OSCILLATOR TYPES

The PIC17CXXX can be operated in four different oscillator modes. The user can program two configuration bits (FOSC1:FOSC0) to select one of these four modes:

- LF Low Power Crystal
- XT Crystal/Resonator
- EC External Clock Input
- RC Resistor/Capacitor

For information on the different oscillator types and how to use them, please refer to Section 4.0.

17.3 Watchdog Timer (WDT)

The Watchdog Timer's function is to recover from software malfunction. The WDT uses an internal free running on-chip RC oscillator for its clock source. This does not require any external components. This RC oscillator is separate from the RC oscillator of the OSC1/CLKIN pin. That means that the WDT will run, even if the clock on the OSC1/CLKIN and OSC2/CLKOUT pins have been stopped, for example, by execution of a `SLEEP` instruction. During normal operation and `SLEEP` mode, a WDT time-out generates a device RESET. The WDT can be permanently disabled by programming the configuration bits `WDTPS1:WDTPS0` as '00' (Section 17.1).

Under normal operation, the WDT must be cleared on a regular interval. This time is less the minimum WDT overflow time. Not clearing the WDT in this time frame will cause the WDT to overflow and reset the device.

17.3.1 WDT PERIOD

The WDT has a nominal time-out period of 12 ms, (with postscaler = 1). The time-out periods vary with temperature, V_{DD} and process variations from part to part (see DC specs). If longer time-out periods are desired, a postscaler with a division ratio of up to 1:256 can be assigned to the WDT. Thus, typical time-out periods up to 3.0 seconds can be realized.

The `CLRWDT` and `SLEEP` instructions clear the WDT and the postscaler (if assigned to the WDT) and prevent it from timing out thus generating a device RESET condition.

The \overline{TO} bit in the `CPUSTA` register will be cleared upon a WDT time-out.

17.3.2 CLEARING THE WDT AND POSTSCALER

The WDT and postscaler are cleared when:

- The device is in the reset state
- A `SLEEP` instruction is executed
- A `CLRWDT` instruction is executed
- Wake-up from `SLEEP` by an interrupt

The WDT counter/postscaler will start counting on the first edge after the device exits the reset state.

17.3.3 WDT PROGRAMMING CONSIDERATIONS

It should also be taken in account that under worst case conditions (V_{DD} = Min., Temperature = Max., max. WDT postscaler) it may take several seconds before a WDT time-out occurs.

The WDT and postscaler is the Power-up Timer during the Power-on Reset sequence.

17.3.4 WDT AS NORMAL TIMER

When the WDT is selected as a normal timer, the clock source is the device clock. Neither the WDT nor the postscaler are directly readable or writable. The overflow time is 65536 TOSC cycles. On overflow, the \overline{TO} bit is cleared (device is not reset). The `CLRWDT` instruction can be used to set the \overline{TO} bit. This allows the WDT to be a simple overflow timer. The simple timer does not increment when in sleep.

FIGURE 17-2: WATCHDOG TIMER BLOCK DIAGRAM

TABLE 17-2: REGISTERS/BITS ASSOCIATED WITH THE WATCHDOG TIMER

Address	Name	Bit 7	Bit 6	Bit 5	Bit 4	Bit 3	Bit 2	Bit 1	Bit 0	Value on POR, BOR	Value on all other resets (Note1)
—	Config	See Figure 17-1 for location of WDTPSx bits in Configuration Word.								(Note 2)	(Note 2)
06h, Unbanked	CPUSTA	—	—	STKAV	GLINTD	\overline{TO}	PD	POR	BOR	--11 1100	--11 qq11

Legend: — = unimplemented read as '0', q - value depends on condition, shaded cells are not used by the WDT.

Note 1: Other (non power-up) resets include: external reset through \overline{MCLR} and Watchdog Timer Reset.

2: This value will be as the device was programmed, or if unprogrammed, will read as all '1's.

17.4 Power-down Mode (SLEEP)

The Power-down mode is entered by executing a `SLEEP` instruction. This clears the Watchdog Timer and postscale (if enabled). The \overline{PD} bit is cleared and the \overline{TO} bit is set (in the `CPUSTA` register). In SLEEP mode, the oscillator driver is turned off. The I/O ports maintain their status (driving high, low, or hi-impedance).

The \overline{MCLR}/VPP pin must be at a logic high level (V_{IHMC}). A WDT time-out RESET does not drive the \overline{MCLR}/VPP pin low.

17.4.1 WAKE-UP FROM SLEEP

The device can wake-up from SLEEP through one of the following events:

- POR
- External reset input on \overline{MCLR}/VPP pin
- WDT Reset (if WDT was enabled)
- BOR
- Interrupt from $RA0/INT$ pin, RB port change, $T0CKI$ interrupt, or some peripheral interrupts

The following peripheral interrupts can wake the device from SLEEP:

- Capture interrupts
- USART synchronous slave transmit interrupts
- USART synchronous slave receive interrupts
- A/D conversion complete
- SPI slave transmit / receive complete
- I^2C slave receive

Other peripherals cannot generate interrupts since during SLEEP, no on-chip Q clocks are present.

Any reset event will cause a device reset. Any interrupt event is considered a continuation of program execution. The \overline{TO} and \overline{PD} bits in the `CPUSTA` register can

be used to determine the cause of device reset. The \overline{PD} bit, which is set on power-up, is cleared when SLEEP is invoked. The \overline{TO} bit is cleared if WDT time-out occurred (and caused wake-up).

When the `SLEEP` instruction is being executed, the next instruction (`PC + 1`) is pre-fetched. For the device to wake-up through an interrupt event, the corresponding interrupt enable bit must be set (enabled). Wake-up is regardless of the state of the `GLINTD` bit. If the `GLINTD` bit is set (disabled), the device continues execution at the instruction after the `SLEEP` instruction. If the `GLINTD` bit is clear (enabled), the device executes the instruction after the `SLEEP` instruction and then branches to the interrupt vector address. In cases where the execution of the instruction following SLEEP is not desirable, the user should have a NOP after the `SLEEP` instruction.

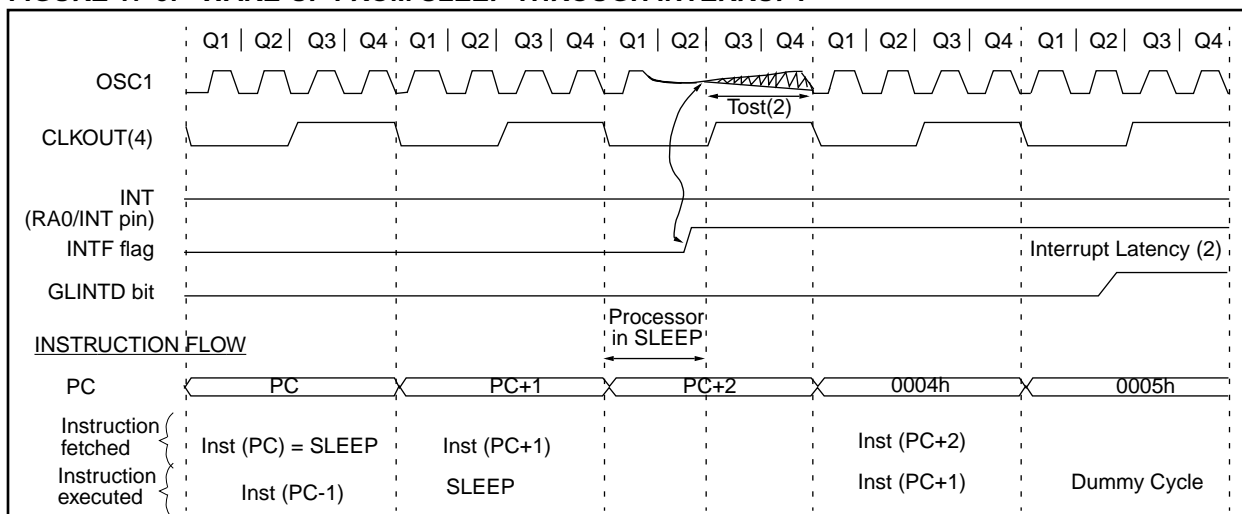

Note: If the global interrupt is disabled (`GLINTD` is set), but any interrupt source has both its interrupt enable bit and the corresponding interrupt flag bit set, the device will immediately wake-up from sleep. The \overline{TO} bit is set, and the \overline{PD} bit is cleared.

The WDT is cleared when the device wakes from SLEEP, regardless of the source of wake-up.

17.4.1.1 WAKE-UP DELAY

When the oscillator type is configured in XT or LF mode, the Oscillator Start-up Timer (OST) is activated on wake-up. The OST will keep the device in reset for $1024T_{osc}$. This needs to be taken into account when considering the interrupt response time when coming out of SLEEP.

FIGURE 17-3: WAKE-UP FROM SLEEP THROUGH INTERRUPT

Note 1: XT or LF oscillator mode assumed.

2: $T_{ost} = 1024T_{osc}$ (drawing not to scale). This delay will not be there for RC osc mode.

3: When `GLINTD` = 0 processor jumps to interrupt routine after wake-up. If `GLINTD` = 1, execution will continue in line.

4: `CLKOUT` is not available in these osc modes, but shown here for timing reference.

17.4.2 MINIMIZING CURRENT CONSUMPTION

To minimize current consumption, all I/O pins should be either at VDD, or VSS, with no external circuitry drawing current from the I/O pin. I/O pins that are hi-impedance inputs should be pulled high or low externally to avoid switching currents caused by floating inputs. The T0CKI input should be at VDD or VSS. The contributions from on-chip pull-ups on PORTB should also be considered, and disabled when possible.

17.5 Code Protection

The code in the program memory can be protected by selecting the microcontroller in code protected mode (PM2:PM0 = '000').

In this mode, instructions that are in the on-chip program memory space, can continue to read or write the program memory. An instruction that is executed outside of the internal program memory range will be inhibited from writing to or reading from program memory.

Note: Microchip does not recommend code protecting windowed devices.

If the code protection bit(s) have not been programmed, the on-chip program memory can be read out for verification purposes.

PIC17C75X

17.6 In-Circuit Serial Programming

The PIC17C75X group of the high end family (PIC17CXXX) has an added feature that allows serial programming while in the end application circuit. This is simply done with two lines for clock and data, and three other lines for power, ground, and the programming voltage. This allows customers to manufacture boards with unprogrammed devices, and then program the microcontroller just before shipping the product. This also allows the most recent firmware or a custom firmware to be programmed.

Devices may be serialized to make the product unique, "special" variants of the product may be offered, and code updates are possible. This allows for increased design flexibility.

To place the device into the serial programming test mode, two pins will need to be placed at V_{IH} . These are the TEST pin and the \overline{MCLR}/V_{PP} pin. Also a sequence of events must occur as follows:

1. The TEST pin is placed at V_{IH} .
2. The \overline{MCLR}/V_{PP} pin is placed at V_{IH} .

There is a setup time between step 1 and step 2 that must be met.

After this sequence the Program Counter is pointing to program memory address 0xFF60. This location is in the Boot ROM. The code initializes the USART/SCI so that it can receive commands. For this, the device must be clocked. The device clock source in this mode is the RA1/T0CKI pin. After delaying to allow the USART/SCI to initialize, commands can be received. The flow is shown in these 3 steps:

1. The device clock source starts.
2. Wait 80 device clocks for Boot ROM code to configure the USART/SCI.
3. Commands may now be sent.

For complete details of serial programming, please refer to the PIC17C75X Programming Specification. (Contact your local Microchip Technology Sales Office for availability.)

\overline{MCLR}/V_{PP}	\overline{MCLR}/V_{PP}	P	Master Clear reset and Device Programming Voltage
VDD	VDD	P	Positive supply for logic and I/O pins
VSS	VSS	P	Ground reference for logic and I/O pins

18.0 INSTRUCTION SET SUMMARY

The PIC17CXXX instruction set consists of 58 instructions. Each instruction is a 16-bit word divided into an OPCODE and one or more operands. The opcode specifies the instruction type, while the operand(s) further specify the operation of the instruction. The PIC17CXXX instruction set can be grouped into three types:

- byte-oriented
- bit-oriented
- literal and control operations.

These formats are shown in Figure 18-1.

Table 18-1 shows the field descriptions for the opcodes. These descriptions are useful for understanding the opcodes in Table 18-2 and in each specific instruction descriptions.

byte-oriented instructions, 'f' represents a file register designator and 'd' represents a destination designator. The file register designator specifies which file register is to be used by the instruction.

The destination designator specifies where the result of the operation is to be placed. If 'd' = '0', the result is placed in the WREG register. If 'd' = '1', the result is placed in the file register specified by the instruction.

bit-oriented instructions, 'b' represents a bit field designator which selects the number of the bit affected by the operation, while 'f' represents the number of the file in which the bit is located.

literal and control operations, 'k' represents an 8- or 13-bit constant or literal value.

The instruction set is highly orthogonal and is grouped into:

- byte-oriented operations
- bit-oriented operations
- literal and control operations

All instructions are executed within one single instruction cycle, unless:

- a conditional test is true
- the program counter is changed as a result of an instruction
- a table read or a table write instruction is executed (in this case, the execution takes two instruction cycles with the second cycle executed as a NOP)

One instruction cycle consists of four oscillator periods. Thus, for an oscillator frequency of 25 MHz, the normal instruction execution time is 160 ns. If a conditional test is true or the program counter is changed as a result of an instruction, the instruction execution time is 320 ns.

TABLE 18-1: OPCODE FIELD DESCRIPTIONS

Field	Description
f	Register file address (00h to FFh)
p	Peripheral register file address (00h to 1Fh)
i	Table pointer control i = '0' (do not change) i = '1' (increment after instruction execution)
t	Table byte select t = '0' (perform operation on lower byte) t = '1' (perform operation on upper byte literal field, constant data)
WREG	Working register (accumulator)
b	Bit address within an 8-bit file register
k	Literal field, constant data or label
x	Don't care location (= '0' or '1') The assembler will generate code with x = '0'. It is the recommended form of use for compatibility with all Microchip software tools.
d	Destination select 0 = store result in WREG 1 = store result in file register f Default is d = '1'
u	Unused, encoded as '0'
s	Destination select 0 = store result in file register f and in the WREG 1 = store result in file register f Default is s = '1'
label	Label name
C, DC, Z, OV	ALU status bits Carry, Digit Carry, Zero, Overflow
GLINTD	Global Interrupt Disable bit (CPUSTA<4>)
TBLPTR	Table Pointer (16-bit)
TBLAT	Table Latch (16-bit) consists of high byte (TBLATH) and low byte (TBLATL)
TBLATL	Table Latch low byte
TBLATH	Table Latch high byte
TOS	Top of Stack
PC	Program Counter
BSR	Bank Select Register
WDT	Watchdog Timer Counter
TO	Time-out bit
PD	Power-down bit
dest	Destination either the WREG register or the specified register file location
[]	Options
()	Contents
→	Assigned to
< >	Register bit field
∈	In the set of
<i>italics</i>	User defined term (font is courier)

Table 18-2 lists the instructions recognized by the MPASM assembler.

Note 1: Any unused opcode is Reserved. Use of any reserved opcode may cause unexpected operation.

All instruction examples use the following format to represent a hexadecimal number:

0xhh

where h signifies a hexadecimal digit.

To represent a binary number:

0000 0100b

where b signifies a binary string.

FIGURE 18-1: GENERAL FORMAT FOR INSTRUCTIONS

18.1 Special Function Registers as Source/Destination

The PIC17C75X's orthogonal instruction set allows read and write of all file registers, including special function registers. There are some special situations the user should be aware of:

18.1.1 ALUSTA AS DESTINATION

If an instruction writes to ALUSTA, the Z, C, DC and OV bits may be set or cleared as a result of the instruction and overwrite the original data bits written. For example, executing `CLRF ALUSTA` will clear register ALUSTA, and then set the Z bit leaving 0000 0100b in the register.

18.1.2 PCL AS SOURCE OR DESTINATION

Read, write or read-modify-write on PCL may have the following results:

Read PC: PCH → PCLATH; PCL → dest

Write PCL: PCLATH → PCH;
8-bit destination value → PCL

Read-Modify-Write: PCL → ALU operand
PCLATH → PCH;
8-bit result → PCL

Where PCH = program counter high byte (not an addressable register), PCLATH = Program counter high holding latch, dest = destination, WREG or f.

18.1.3 BIT MANIPULATION

All bit manipulation instructions are done by first reading the entire register, operating on the selected bit and writing the result back (read-modify-write (R-M-W)). The user should keep this in mind when operating on some special function registers, such as ports.

Note: Status bits that are manipulated by the device (including the Interrupt flag bits) are set or cleared in the Q1 cycle. So there is no issue on doing R-M-W instructions on registers which contain these bits

18.2 Q Cycle Activity

Each instruction cycle (Tcy) is comprised of four Q cycles (Q1-Q4). The Q cycle is the same as the device oscillator cycle (Tosc). The Q cycles provide the timing/designation for the Decode, Read, Process Data, Write etc., of each instruction cycle. The following diagram shows the relationship of the Q cycles to the instruction cycle.

The four Q cycles that make up an instruction cycle (Tcy) can be generalized as:

Q1: Instruction Decode Cycle or forced No operation

Q2: Instruction Read Cycle or No operation

Q3: Process the Data

Q4: Instruction Write Cycle or No operation

Each instruction will show the detailed Q cycle operation for the instruction.

FIGURE 18-2: Q CYCLE ACTIVITY

TABLE 18-2: PIC17CXXX INSTRUCTION SET

Mnemonic, Operands	Description	Cycles	16-bit Opcode		Status Affected	Notes
			MSb	LSb		
BYTE-ORIENTED FILE REGISTER OPERATIONS						
ADDWF	f,d	ADD WREG to f	1	0000 111d ffff ffff	OV,C,DC,Z	
ADDWFC	f,d	ADD WREG and Carry bit to f	1	0001 000d ffff ffff	OV,C,DC,Z	
ANDWF	f,d	AND WREG with f	1	0000 101d ffff ffff	Z	
CLRF	f,s	Clear f, or Clear f and Clear WREG	1	0010 100s ffff ffff	None	3
COMF	f,d	Complement f	1	0001 001d ffff ffff	Z	
CPFSEQ	f	Compare f with WREG, skip if f = WREG	1 (2)	0011 0001 ffff ffff	None	6,8
CPFSGT	f	Compare f with WREG, skip if f > WREG	1 (2)	0011 0010 ffff ffff	None	2,6,8
CPFSLT	f	Compare f with WREG, skip if f < WREG	1 (2)	0011 0000 ffff ffff	None	2,6,8
DAW	f,s	Decimal Adjust WREG Register	1	0010 111s ffff ffff	C	3
DECf	f,d	Decrement f	1	0000 011d ffff ffff	OV,C,DC,Z	
DECFSZ	f,d	Decrement f, skip if 0	1 (2)	0001 011d ffff ffff	None	6,8
DCFSNZ	f,d	Decrement f, skip if not 0	1 (2)	0010 011d ffff ffff	None	6,8
INCF	f,d	Increment f	1	0001 010d ffff ffff	OV,C,DC,Z	
INCFSZ	f,d	Increment f, skip if 0	1 (2)	0001 111d ffff ffff	None	6,8
INFSNZ	f,d	Increment f, skip if not 0	1 (2)	0010 010d ffff ffff	None	6,8
IORWF	f,d	Inclusive OR WREG with f	1	0000 100d ffff ffff	Z	
MOVFP	f,p	Move f to p	1	011p pppp ffff ffff	None	
MOVPF	p,f	Move p to f	1	010p pppp ffff ffff	Z	
MOVWF	f	Move WREG to f	1	0000 0001 ffff ffff	None	
MULWF	f	Multiply WREG with f	1	0011 0100 ffff ffff	None	
NEGf	f,s	Negate WREG	1	0010 110s ffff ffff	OV,C,DC,Z	1,3
NOP	—	No Operation	1	0000 0000 0000 0000	None	
RLCF	f,d	Rotate left f through Carry	1	0001 101d ffff ffff	C	
RLNCF	f,d	Rotate left f (no carry)	1	0010 001d ffff ffff	None	
RRCF	f,d	Rotate right f through Carry	1	0001 100d ffff ffff	C	
RRNCF	f,d	Rotate right f (no carry)	1	0010 000d ffff ffff	None	
SETf	f,s	Set f	1	0010 101s ffff ffff	None	3
SUBWF	f,d	Subtract WREG from f	1	0000 010d ffff ffff	OV,C,DC,Z	1
SUBWFB	f,d	Subtract WREG from f with Borrow	1	0000 001d ffff ffff	OV,C,DC,Z	1
SWAPf	f,d	Swap f	1	0001 110d ffff ffff	None	
TABLRD	t,i,f	Table Read	2 (3)	1010 10ti ffff ffff	None	7
TABLWT	t,i,f	Table Write	2	1010 11ti ffff ffff	None	5

Legend: Refer to Table 18-1 for opcode field descriptions.

Note 1: 2's Complement method.

2: Unsigned arithmetic.

3: If s = '1', only the file is affected: If s = '0', both the WREG register and the file are affected; If only the Working register (WREG) is required to be affected, then f = WREG must be specified.

4: During an **LCALL**, the contents of PCLATH are loaded into the MSB of the PC and kkkk kkkk is loaded into the LSB of the PC (PCL)

5: Multiple cycle instruction for EPROM programming when table pointer selects internal EPROM. The instruction is terminated by an interrupt event. When writing to external program memory, it is a two-cycle instruction.

6: Two-cycle instruction when condition is true, else single cycle instruction.

7: Two-cycle instruction except for **TABLRD** to PCL (program counter low byte) in which case it takes 3 cycles.

8: A "skip" means that instruction fetched during execution of current instruction is not executed, instead an NOP is executed.

TABLE 18-2: PIC17CXXX INSTRUCTION SET (Cont.'d)

Mnemonic, Operands	Description	Cycles	16-bit Opcode				Status Affected	Notes	
			MSb		LSb				
TLRD	t,f	Table Latch Read	1	1010	00tx	ffff	ffff	None

MULLW	k	Multiply literal with WREG	1	1011	1100	kkkk	kkkk	None	
RETFIE	—	Return from interrupt (and enable interrupts)	2	0000	0000	0000	0101	GLINTD	7
RETLW	k	Return literal to WREG	2	1011	0110	kkkk	kkkk	None	7
RETURN	—	Return from subroutine	2	0000	0000	0000	0010	None	7
SLEEP	—	Enter SLEEP Mode	1	0000	0000	0000	0011	$\overline{TO}, \overline{PD}$	
SUBLW	k	Subtract WREG from literal	1	1011	0010	kkkk	kkkk	OV,C,DC,Z	
XORLW	k	Exclusive OR literal with WREG	1	1011	0100	kkkk	kkkk	Z	

Legend: Refer to Table 18-1 for opcode field descriptions.

Note 1: 2's Complement method.

2: Unsigned arithmetic.

3: If s = '1', only the file is affected; If s = '0', both the WREG register and the file are affected; If only the Working register (WREG) is required to be affected, then f = WREG must be specified.

4: During an LCALL, the contents of PCLATH are loaded into the MSB of the PC and kkkk kkkk is loaded into the LSB of the PC (PCL)

5: Multiple cycle instruction for EPROM programming when table pointer selects internal EPROM. The instruction is terminated by an interrupt event. When writing to external program memory, it is a two-cycle instruction.

6: Two-cycle instruction when condition is true, else single cycle instruction.

7: Two-cycle instruction except for TABLRD to PCL (program counter low byte) in which case it takes 3 cycles.

8: A "skip" means that instruction fetched during execution of current instruction is not executed, instead an NOP is executed.

ADDLW

ADD Literal to WREG

Syntax: [*label*] ADDLW k

Operands: $0 \leq k \leq 255$

Operation: (WREG) + k → (WREG)

Status Affected: OV, C, DC, Z

Encoding:

1011	0001	kkkk	kkkk
------	------	------	------

Description: The contents of WREG are added to the 8-bit literal 'k' and the result is placed in WREG.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Process Data	Write to WREG

Example: ADDLW 0x15

Before Instruction
WREG = 0x10

After Instruction
WREG = 0x25

ADDWF

ADD WREG to f

Syntax: [*label*] ADDWF f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: (WREG) + (f) → (dest)

Status Affected: OV, C, DC, Z

Encoding:

0000	111d	ffff	ffff
------	------	------	------

Description: Add WREG to register 'f'. If 'd' is 0 the result is stored in WREG. If 'd' is 1 the result is stored back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: ADDWF REG, 0

Before Instruction
WREG = 0x17
REG = 0xC2

After Instruction
WREG = 0xD9
REG = 0xC2

ADDWFC		ADD WREG and Carry bit to f						
Syntax:	[<i>label</i>] ADDWFC f,d							
Operands:	0 ≤ f ≤ 255 d ∈ [0,1]							
Operation:	(WREG) + (f) + C → (dest)							
Status Affected:	OV, C, DC, Z							
Encoding:	<table border="1"><tr><td>0001</td><td>000d</td><td>ffff</td><td>ffff</td></tr></table>				0001	000d	ffff	ffff
0001	000d	ffff	ffff					
Description:	Add WREG, the Carry Flag and data memory location 'f'. If 'd' is 0, the result is placed in WREG. If 'd' is 1, the result is placed in data memory location 'f'.							
Words:	1							
Cycles:	1							
Q Cycle Activity:								
	Q1	Q2	Q3	Q4				
	Decode	Read register 'f'	Process Data	Write to destination				

Example: ADDWFC REG 0

Before Instruction

Carry bit = 1
REG = 0x02
WREG = 0x4D

After Instruction

Carry bit = 0
REG = 0x02
WREG = 0x50

ANDLW		And Literal with WREG						
Syntax:	[<i>label</i>] ANDLW k							
Operands:	0 ≤ k ≤ 255							
Operation:	(WREG) .AND. (k) → (WREG)							
Status Affected:	Z							
Encoding:	<table border="1"><tr><td>1011</td><td>0101</td><td>kkkk</td><td>kkkk</td></tr></table>				1011	0101	kkkk	kkkk
1011	0101	kkkk	kkkk					
Description:	The contents of WREG are AND'ed with the 8-bit literal 'k'. The result is placed in WREG.							
Words:	1							
Cycles:	1							
Q Cycle Activity:								
	Q1	Q2	Q3	Q4				
	Decode	Read literal 'k'	Process Data	Write to WREG				

Example: ANDLW 0x5F

Before Instruction

WREG = 0xA3

After Instruction

WREG = 0x03

ANDWF

AND WREG with f

Syntax:

[/label] ANDWF f,d

Operands:

$0 \leq f \leq 255$

$d \in [0,1]$

Operation:

(WREG) .AND. (f) → (dest)

Status Affected:

Z

Encoding:

0000	101d	ffff	ffff
------	------	------	------

Description:

The contents of WREG are AND'ed with register 'f'. If 'd' is 0 the result is stored in WREG. If 'd' is 1 the result is stored back in register 'f'.

Words:

1

Cycles:

1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: ANDWF REG, 1

Before Instruction

WREG = 0x17

REG = 0xC2

After Instruction

WREG = 0x17

REG = 0x02

BCF

Bit Clear f

Syntax:

[/label] BCF f,b

Operands:

$0 \leq f \leq 255$

$0 \leq b \leq 7$

Operation:

$0 \rightarrow (f)$

Status Affected:

None

Encoding:

1000	1bbb	ffff	ffff
------	------	------	------

Description:

Bit 'b' in register 'f' is cleared.

Words:

1

Cycles:

1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write register 'f'

Example: BCF FLAG_REG, 7

Before Instruction

FLAG_REG = 0xC7

After Instruction

FLAG_REG = 0x47

BSF		Bit Set f			
Syntax:	[<i>label</i>] BSF f,b				
Operands:	$0 \leq f \leq 255$ $0 \leq b \leq 7$				
Operation:	$1 \rightarrow (f < b >)$				
Status Affected:	None				
Encoding:	1000	0bbb	ffff	ffff	
Description:	Bit 'b' in register 'f' is set.				
Words:	1				
Cycles:	1				
Q Cycle Activity:					
	Q1	Q2	Q3	Q4	
	Decode	Read register 'f'	Process Data	Write register 'f'	

Example: BSF FLAG_REG, 7

Before Instruction
FLAG_REG= 0x0A
After Instruction
FLAG_REG= 0x8A

BTFSC		Bit Test, skip if Clear							
Syntax:	[<i>label</i>] BTFSC f,b								
Operands:	$0 \leq f \leq 255$ $0 \leq b \leq 7$								
Operation:	skip if (f) = 0								
Status Affected:	None								
Encoding:	<table border="1"><tr><td>1001</td><td>1bbb</td><td>ffff</td><td>ffff</td></tr></table>					1001	1bbb	ffff	ffff
1001	1bbb	ffff	ffff						
Description:	<p>If bit 'b' in register 'f' is 0 then the next instruction is skipped.</p> <p>If bit 'b' is 0 then the next instruction fetched during the current instruction execution is discarded, and a NOP is executed instead, making this a two-cycle instruction.</p>								
Words:	1								
Cycles:	1(2)								

If skip:

Q1	Q2	Q3	Q4
No operation	No operation	No operation	No operation

Example: HERE BTFSC FLAG,1
FALSE :
TRUE :

Before Instruction
PC = address (HERE)
After Instruction
If FLAG<1> = 0;
PC = address (TRUE)
If FLAG<1> = 1;
PC = address (FALSE)

BTFSS

Bit Test, skip if Set

Syntax: [*label*] BTFSS *f*,*b*

Operands: $0 \leq f \leq 127$
 $0 \leq b < 7$

Operation: skip if (*f*<*b*>) = 1

Status Affected: None

Encoding:

1001	0bbb	ffff	ffff
------	------	------	------

Description: If bit '*b*' in register '*f*' is 1 then the next instruction is skipped.
 If bit '*b*' is 1, then the next instruction fetched during the current instruction execution, is discarded and an NOP is executed instead, making this a two-cycle instruction.

Words: 1

Cycles: 1(2)

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register ' <i>f</i> '	Process Data	No operation

If skip:

Q1	Q2	Q3	Q4
No operation	No operation	No operation	No operation

Example:

```

HERE    BTFSS    FLAG,1
FALSE   :
TRUE    :
```

Before Instruction

PC = address (HERE)

After Instruction

```

If FLAG<1> = 0;
PC = address (FALSE)
If FLAG<1> = 1;
PC = address (TRUE)
```

BTG

Bit Toggle *f*

Syntax: [*label*] BTG *f*,*b*

Operands: $0 \leq f \leq 255$
 $0 \leq b < 7$

Operation: ($\overline{f\langle b \rangle}$) → (*f*<*b*>)

Status Affected: None

Encoding:

0011	1bbb	ffff	ffff
------	------	------	------

Description: Bit '*b*' in data memory location '*f*' is inverted.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register ' <i>f</i> '	Process Data	Write register ' <i>f</i> '

Example: BTG PORTC, 4

Before Instruction:

PORTC = 0111 0101 [0x75]

After Instruction:

PORTC = 0110 0101 [0x65]

CALL		Subroutine Call							
Syntax:	[<i>label</i>] CALL k								
Operands:	0 ≤ k ≤ 4095								
Operation:	PC+ 1 → TOS, k → PC<12:0>, k<12:8> → PCLATH<4:0>; PC<15:13> → PCLATH<7:5>								
Status Affected:	None								
Encoding:	<table><tr><td>111k</td><td>kkkk</td><td>kkkk</td><td>kkkk</td></tr></table>					111k	kkkk	kkkk	kkkk
111k	kkkk	kkkk	kkkk						
Description:	<p>Subroutine call within 8K page. First, return address (PC+1) is pushed onto the stack. The 13-bit value is loaded into PC bits<12:0>. Then the upper-eight bits of the PC are copied into PCLATH. CALL is a two-cycle instruction.</p> <p>See LCALL for calls outside 8K memory space.</p>								
Words:	1								
Cycles:	2								
Q Cycle Activity:									
	Q1	Q2	Q3	Q4					
	Decode	Read literal 'k'<7:0>, Push PC to stack	Process Data	Write to PC					
	No operation	No operation	No operation	No operation					

Example: HERE CALL THERE

Before Instruction

PC = Address (HERE)

After Instruction

PC = Address (THERE)

TOS = Address (HERE + 1)

CLRF		Clear f							
Syntax:	[label] CLRF f,s								
Operands:	$0 \leq f \leq 255$								
Operation:	00h \rightarrow f, s \in [0,1] 00h \rightarrow dest								
Status Affected:	None								
Encoding:	<table border="1"><tr><td>0010</td><td>100s</td><td>ffff</td><td>ffff</td></tr></table>					0010	100s	ffff	ffff
0010	100s	ffff	ffff						
Description:	Clears the contents of the specified register(s). s = 0: Data memory location 'f' and WREG are cleared. s = 1: Data memory location 'f' is cleared.								
Words:	1								
Cycles:	1								
Q Cycle Activity:									
	Q1	Q2	Q3	Q4					
	Decode	Read register 'f'	Process Data	Write register 'f' and if specified WREG					

Example: CLRF FLAG_REG

Before Instruction

FLAG_REG = 0x5A

After Instruction

FLAG_REG = 0x00

CLRWDT

Clear Watchdog Timer

Syntax: [label] CLRWDT

Operands: None

Operation: 00h → WDT
0 → WDT postscaler,
1 → \overline{TO}
1 → \overline{PD}

Status Affected: \overline{TO} , \overline{PD}

Encoding:

0000	0000	0000	0100
------	------	------	------

Description: CLRWDT instruction resets the Watchdog Timer. It also resets the prescaler of the WDT. Status bits \overline{TO} and \overline{PD} are set.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	No operation	Process Data	No operation

Example: CLRWDT

Before Instruction

WDT counter = ?

After Instruction

WDT counter = 0x00

WDT Postscaler = 0

\overline{TO} = 1

\overline{PD} = 1

COMF

Complement f

Syntax: [label] COMF f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(\overline{f}) \rightarrow (\text{dest})$

Status Affected: Z

Encoding:

0001	001d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are complemented. If 'd' is 0 the result is stored in WREG. If 'd' is 1 the result is stored back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: COMF REG1, 0

Before Instruction

REG1 = 0x13

After Instruction

REG1 = 0x13

WREG = 0xEC

CPFSEQ		Compare f with WREG, skip if f = WREG							
Syntax:	[<i>label</i>] CPFSEQ f								
Operands:	0 ≤ f ≤ 255								
Operation:	(f) – (WREG), skip if (f) = (WREG) (unsigned comparison)								
Status Affected:	None								
Encoding:	<table><tr><td>0011</td><td>0001</td><td>ffff</td><td>ffff</td></tr></table>					0011	0001	ffff	ffff
0011	0001	ffff	ffff						
Description:	Compares the contents of data memory location 'f' to the contents of WREG by performing an unsigned subtraction. If 'f' = WREG then the fetched instruction is discarded and an NOP is executed instead making this a two-cycle instruction.								
Words:	1								
Cycles:	1 (2)								
Q Cycle Activity:									
	Q1	Q2	Q3	Q4					
	Decode	Read register 'f'	Process Data	No operation					
If skip:									
	Q1	Q2	Q3	Q4					
	No operation	No operation	No operation	No operation					

Example:

```

HERE    CPFSEQ REG
NEQUAL  :
EQUAL   :

```

Before Instruction

```

PC Address = HERE
WREG       = ?
REG        = ?

```

After Instruction

```

If REG     = WREG;
PC         = Address (EQUAL)
If REG     ≠ WREG;
PC         = Address (NEQUAL)

```

CPFSGT		Compare f with WREG, skip if f > WREG							
Syntax:	[<i>label</i>] CPFSGT f								
Operands:	$0 \leq f \leq 255$								
Operation:	(f) – (WREG), skip if (f) > (WREG) (unsigned comparison)								
Status Affected:	None								
Encoding:	<table><tr><td>0011</td><td>0010</td><td>ffff</td><td>ffff</td></tr></table>					0011	0010	ffff	ffff
0011	0010	ffff	ffff						
Description:	Compares the contents of data memory location 'f' to the contents of the WREG by performing an unsigned subtraction. If the contents of 'f' are greater than the contents of WREG then the fetched instruction is discarded and an NOP is executed instead making this a two-cycle instruction.								
Words:	1								
Cycles:	1 (2)								
Q Cycle Activity:									
	Q1	Q2	Q3	Q4					
	Decode	Read register 'f'	Process Data	No operation					
If skip:									
	Q1	Q2	Q3	Q4					
	No operation	No operation	No operation	No operation					

Example:

```

HERE    CPFSGT REG
NGREATER :
GREATER  :

```

Before Instruction

```

PC       = Address (HERE)
WREG     = ?

```

After Instruction

```

If REG   > WREG;
PC       = Address (GREATER)
If REG   ≤ WREG;
PC       = Address (NGREATER)

```

CPFSLT Compare f with WREG, skip if f < WREG

Syntax: `[label] CPFSLT f`

Operands: $0 \leq f \leq 255$

Operation: (f) – (WREG), skip if (f) < (WREG) (unsigned comparison)

Status Affected: None

Encoding:

0011	0000	ffff	ffff
------	------	------	------

Description: Compares the contents of data memory location 'f' to the contents of WREG by performing an unsigned subtraction. If the contents of 'f' are less than the contents of WREG, then the fetched instruction is discarded and an NOP is executed instead making this a two-cycle instruction.

Words: 1

Cycles: 1 (2)

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	No operation

If skip:

Q1	Q2	Q3	Q4
No operation	No operation	No operation	No operation

Example:

```

HERE    CPFSLT REG
NLESS   :
LESS    :
```

Before Instruction

```

PC      = Address (HERE)
W       = ?
```

After Instruction

```

If REG < WREG;
PC      = Address (LESS)
If REG ≥ WREG;
PC      = Address (NLESS)
```

DAW Decimal Adjust WREG Register

Syntax: `[label] DAW f,s`

Operands: $0 \leq f \leq 255$
 $s \in [0,1]$

Operation: If [WREG<3:0> >9] .OR. [DC = 1] then
WREG<3:0> + 6 → f<3:0>, s<3:0>;
else
WREG<3:0> → f<3:0>, s<3:0>;

If [WREG<7:4> >9] .OR. [C = 1] then
WREG<7:4> + 6 → f<7:4>, s<7:4>;
else
WREG<7:4> → f<7:4>, s<7:4>;

Status Affected: C

Encoding:

0010	111s	ffff	ffff
------	------	------	------

Description: DAW adjusts the eight bit value in WREG resulting from the earlier addition of two variables (each in packed BCD format) and produces a correct packed BCD result.

s = 0: Result is placed in Data memory location 'f' and WREG.

s = 1: Result is placed in Data memory location 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write register 'f' and other specified register

Example1: DAW REG1, 0

Before Instruction

```

WREG = 0xA5
REG1 = ??
C    = 0
DC   = 0
```

After Instruction

```

WREG = 0x05
REG1 = 0x05
C    = 1
DC   = 0
```

Example 2:

Before Instruction

```

WREG = 0xCE
REG1 = ??
C    = 0
DC   = 0
```

After Instruction

```

WREG = 0x24
REG1 = 0x24
C    = 1
DC   = 0
```

DECF Decrement f

Syntax: [*label*] DECF f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) - 1 \rightarrow (\text{dest})$

Status Affected: OV, C, DC, Z

Encoding:

0000	011d	ffff	ffff
------	------	------	------

Description: Decrement register 'f'. If 'd' is 0 the result is stored in WREG. If 'd' is 1 the result is stored back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: DECF CNT, 1

Before Instruction

CNT = 0x01
Z = 0

After Instruction

CNT = 0x00
Z = 1

DECFSZ Decrement f, skip if 0

Syntax: [*label*] DECFSZ f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) - 1 \rightarrow (\text{dest})$;
skip if result = 0

Status Affected: None

Encoding:

0001	011d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are decremented. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed back in register 'f'.

If the result is 0, the next instruction, which is already fetched, is discarded, and an NOP is executed instead making it a two-cycle instruction.

Words: 1

Cycles: 1(2)

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

If skip:

Q1	Q2	Q3	Q4
No operation	No operation	No operation	No operation

Example: HERE DECFSZ CNT, 1
 GOTO LOOP
 CONTINUE

Before Instruction

PC = Address (HERE)

After Instruction

CNT = CNT - 1
If CNT = 0;
PC = Address (CONTINUE)
If CNT \neq 0;
PC = Address (HERE+1)

PIC17C75X

DCFSNZ Decrement f, skip if not 0

Syntax: `[label] DCFSNZ f,d`

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) - 1 \rightarrow (\text{dest});$
 skip if not 0

Status Affected: None

Encoding:

0010	011d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are decremented. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed back in register 'f'.

If the result is not 0, the next instruction, which is already fetched, is discarded, and an NOP is executed instead making it a two-cycle instruction.

Words: 1

Cycles: 1(2)

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

If skip:

Q1	Q2	Q3	Q4
No operation	No operation	No operation	No operation

Example:

```

HERE    DCFSNZ    TEMP, 1
ZERO    :
NZERO   :
```

Before Instruction

TEMP_VALUE = ?

After Instruction

TEMP_VALUE = TEMP_VALUE - 1,

If TEMP_VALUE = 0;

PC = Address (ZERO)

If TEMP_VALUE \neq 0;

PC = Address (NZERO)

GOTO Unconditional Branch

Syntax: `[label] GOTO k`

Operands: $0 \leq k \leq 8191$

Operation: $k \rightarrow \text{PC}<12:0>;$
 $k<12:8> \rightarrow \text{PCLATH}<4:0>;$
 $\text{PC}<15:13> \rightarrow \text{PCLATH}<7:5>$

Status Affected: None

Encoding:

110k	kkkk	kkkk	kkkk
------	------	------	------

Description: GOTO allows an unconditional branch anywhere within an 8K page boundary. The thirteen bit immediate value is loaded into PC bits <12:0>. Then the upper eight bits of PC are loaded into PCLATH. GOTO is always a two-cycle instruction.

Words: 1

Cycles: 2

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Process Data	Write to PC
No operation	No operation	No operation	No operation

Example: GOTO THERE

After Instruction

PC = Address (THERE)

INCF Increment f

Syntax: [*label*] INCF f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) + 1 \rightarrow (\text{dest})$

Status Affected: OV, C, DC, Z

Encoding:

0001	010d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are incremented. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: INCF CNT, 1

Before Instruction

CNT = 0xFF
 Z = 0
 C = ?

After Instruction

CNT = 0x00
 Z = 1
 C = 1

INCFSZ Increment f, skip if 0

Syntax: [*label*] INCFSZ f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) + 1 \rightarrow (\text{dest})$
 skip if result = 0

Status Affected: None

Encoding:

0001	111d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are incremented. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed back in register 'f'.

If the result is 0, the next instruction, which is already fetched, is discarded, and an NOP is executed instead making it a two-cycle instruction.

Words: 1

Cycles: 1(2)

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

If skip:

Q1	Q2	Q3	Q4
No operation	No operation	No operation	No operation

Example: HERE INCFSZ CNT, 1
 NZERO :
 ZERO :

Before Instruction

PC = Address (HERE)

After Instruction

CNT = CNT + 1
 If CNT = 0;
 PC = Address (ZERO)
 If CNT \neq 0;
 PC = Address (NZERO)

INFSNZ Increment f, skip if not 0

Syntax: `[label] INFSNZ f,d`

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) + 1 \rightarrow (\text{dest})$,
 skip if not 0

Status Affected: None

Encoding:

0010	010d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are incremented. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed back in register 'f'.
 If the result is not 0, the next instruction, which is already fetched, is discarded, and an NOP is executed instead making it a two-cycle instruction.

Words: 1

Cycles: 1(2)

Decode	Read register 'f'	Process Data	Write to destination

If skip:

Q1	Q2	Q3	Q4
No operation	No operation	No operation	No operation

Example:

```

HERE    INFSNZ  REG, 1
ZERO
NZERO
  
```

Before Instruction

REG = REG

After Instruction

REG = REG + 1

If REG = 1;

PC = Address (ZERO)

If REG = 0;

PC = Address (NZERO)

IORLW Inclusive OR Literal with WREG

Syntax: `[label] IORLW k`

Operands: $0 \leq k \leq 255$

Operation: $(\text{WREG}) .\text{OR}. (k) \rightarrow (\text{WREG})$

Status Affected: Z

Encoding:

1011	0011	kkkk	kkkk
------	------	------	------

Description: The contents of WREG are OR'ed with the eight bit literal 'k'. The result is placed in WREG.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Process Data	Write to WREG

Example: IORLW 0x35

Before Instruction

WREG = 0x9A

After Instruction

WREG = 0xBF

IORWF		Inclusive OR WREG with f						
Syntax:	[<i>label</i>] IORWF f,d							
Operands:	$0 \leq f \leq 255$ $d \in [0,1]$							
Operation:	(WREG) .OR. (f) \rightarrow (dest)							
Status Affected:	\bar{Z}							
Encoding:	<table border="1"><tr><td>0000</td><td>100d</td><td>ffff</td><td>ffff</td></tr></table>				0000	100d	ffff	ffff
0000	100d	ffff	ffff					
Description:	Inclusive OR WREG with register 'f'. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed back in register 'f'.							
Words:	1							
Cycles:	1							
Q Cycle Activity:								
	Q1	Q2	Q3	Q4				
	Decode	Read register 'f'	Process Data	Write to destination				

Example: IORWF RESULT, 0

Before Instruction

RESULT = 0x13
WREG = 0x91

After Instruction

RESULT = 0x13
WREG = 0x93

LCALL		Long Call							
Syntax:	[<i>label</i>] LCALL k								
Operands:	$0 \leq k \leq 255$								
Operation:	PC + 1 \rightarrow TOS; k \rightarrow PCL, (PCLATH) \rightarrow PCH								
Status Affected:	None								
Encoding:	<table border="1"><tr><td>1011</td><td>0111</td><td>kkkk</td><td>kkkk</td></tr></table>					1011	0111	kkkk	kkkk
1011	0111	kkkk	kkkk						
Description:	<p>LCALL allows an unconditional subroutine call to anywhere within the 64K program memory space.</p> <p>First, the return address (PC + 1) is pushed onto the stack. A 16-bit destination address is then loaded into the program counter. The lower 8-bits of the destination address is embedded in the instruction. The upper 8-bits of PC is loaded from PC high holding latch, PCLATH.</p>								
Words:	1								
Cycles:	2								
Q Cycle Activity:									
Q1		Q2		Q3		Q4			
Decode		Read literal 'k'		Process Data		Write register PCL			
No operation		No operation		No operation		No operation			

Example: MOVLW HIGH(SUBROUTINE)
MOVFPF WREG, PCLATH
LCALL LOW(SUBROUTINE)

Before Instruction

SUBROUTINE = 16-bit Address
PC = ?

After Instruction

PC = Address (SUBROUTINE)

MOVFP Move f to p

Syntax:	[<i>label</i>] MOVFP f,p			
Operands:	$0 \leq f \leq 255$ $0 \leq p \leq 31$			
Operation:	(f) → (p)			
Status Affected:	None			
Encoding:	011p	pppp	ffff	ffff
Description:	<p>Move data from data memory location 'f' to data memory location 'p'. Location 'f' can be anywhere in the 256 word data space (00h to FFh) while 'p' can be 00h to 1Fh.</p> <p>Either 'p' or 'f' can be WREG (a useful special situation).</p> <p>MOVFP is particularly useful for transferring a data memory location to a peripheral register (such as the transmit buffer or an I/O port). Both 'f' and 'p' can be indirectly addressed.</p>			
Words:	1			
Cycles:	1			
Q Cycle Activity:				
	Q1	Q2	Q3	Q4
	Decode	Read register 'f'	Process Data	Write register 'p'

Example: MOVFP REG1, REG2

Before Instruction

REG1 = 0x33,
REG2 = 0x11

After Instruction

REG1 = 0x33,
REG2 = 0x33

MOVLB Move Literal to low nibble in BSR

Syntax:	[<i>label</i>] MOVLB k								
Operands:	0 ≤ k ≤ 15								
Operation:	k → (BSR<3:0>)								
Status Affected:	None								
Encoding:	<table><tr><td>1011</td><td>1000</td><td>uuuu</td><td>kkkk</td></tr></table>	1011	1000	uuuu	kkkk				
1011	1000	uuuu	kkkk						
Description:	<p>The four bit literal 'k' is loaded in the Bank Select Register (BSR). Only the low 4-bits of the Bank Select Register are affected. The upper half of the BSR is unchanged. The assembler will encode the "u" fields as '0'.</p>								
Words:	1								
Cycles:	1								
Q Cycle Activity:									
	<table><tr><td>Q1</td><td>Q2</td><td>Q3</td><td>Q4</td></tr><tr><td>Decode</td><td>Read literal 'k'</td><td>Process Data</td><td>Write literal 'k' to BSR<3:0></td></tr></table>	Q1	Q2	Q3	Q4	Decode	Read literal 'k'	Process Data	Write literal 'k' to BSR<3:0>
Q1	Q2	Q3	Q4						
Decode	Read literal 'k'	Process Data	Write literal 'k' to BSR<3:0>						

Example: MOVLB 5

Before Instruction

BSR register = 0x22

After Instruction

BSR register = 0x25 (Bank 5)

MOVLW Move Literal to high nibble in BSR

Syntax: [*label*] MOVLW *k*

Operands: $0 \leq k \leq 15$

Operation: $k \rightarrow (\text{BSR} \langle 7:4 \rangle)$

Status Affected: None

Encoding:

1011	101x	kkkk	uuuu
------	------	------	------

Description: The 4-bit literal 'k' is loaded into the most significant 4-bits of the Bank Select Register (BSR). Only the high 4-bits of the Bank Select Register are affected. The lower half of the BSR is unchanged. The assembler will encode the "u" fields as 0.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Process Data	Write literal 'k' to BSR<7:4>

Example: MOVLW 5

Before Instruction

BSR register = 0x22

After Instruction

BSR register = 0x52

MOVLW Move Literal to WREG

Syntax: [*label*] MOVLW *k*

Operands: $0 \leq k \leq 255$

Operation: $k \rightarrow (\text{WREG})$

Status Affected: None

Encoding:

1011	0000	kkkk	kkkk
------	------	------	------

Description: The eight bit literal 'k' is loaded into WREG.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Process Data	Write to WREG

Example: MOVLW 0x5A

After Instruction

WREG = 0x5A

MOVPF Move p to f

Syntax: `[label] MOVPF p,f`

Operands: $0 \leq f \leq 255$
 $0 \leq p \leq 31$

Operation: $(p) \rightarrow (f)$

Status Affected: Z

Encoding:

010p	pppp	ffff	ffff
------	------	------	------

Description: Move data from data memory location 'p' to data memory location 'f'. Location 'f' can be anywhere in the 256 byte data space (00h to FFh) while 'p' can be 00h to 1Fh.

Either 'p' or 'f' can be WREG (a useful special situation).

MOVPF is particularly useful for transferring a peripheral register (e.g. the timer or an I/O port) to a data memory location. Both 'f' and 'p' can be indirectly addressed.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'p'	Process Data	Write register 'f'

Example: `MOVPF REG1, REG2`

Before Instruction

REG1 = 0x11
 REG2 = 0x33

After Instruction

REG1 = 0x11
 REG2 = 0x11

MOVWF Move WREG to f

Syntax: `[label] MOVWF f`

Operands: $0 \leq f \leq 255$

Operation: $(WREG) \rightarrow (f)$

Status Affected: None

Encoding:

0000	0001	ffff	ffff
------	------	------	------

Description: Move data from WREG to register 'f'. Location 'f' can be anywhere in the 256 word data space.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write register 'f'

Example: `MOVWF REG`

Before Instruction

WREG = 0x4F
 REG = 0xFF

After Instruction

WREG = 0x4F
 REG = 0x4F

MULLW		Multiply Literal with WREG			
Syntax:	[<i>label</i>] MULLW k				
Operands:	0 ≤ k ≤ 255				
Operation:	(k x WREG) → PRODH:PRODL				
Status Affected:	None				
Encoding:	1011	1100	kkkk	kkkk	
Description:	<p>An unsigned multiplication is carried out between the contents of WREG and the 8-bit literal 'k'. The 16-bit result is placed in PRODH:PRODL register pair. PRODH contains the high byte.</p> <p>WREG is unchanged.</p> <p>None of the status flags are affected.</p> <p>Note that neither overflow nor carry is possible in this operation. A zero result is possible but not detected.</p>				
Words:	1				
Cycles:	1				
Q Cycle Activity:					
	Q1	Q2	Q3	Q4	
	Decode	Read literal 'k'	Process Data	Write registers PRODH: PRODL	

Example: MULLW 0xC4

Before Instruction

WREG = 0xE2
 PRODH = ?
 PRODL = ?

After Instruction

WREG = 0xC4
 PRODH = 0xAD
 PRODL = 0x08

MULWF		Multiply WREG with f											
Syntax:	[<i>label</i>] MULWF f												
Operands:	$0 \leq f \leq 255$												
Operation:	$(\text{WREG} \times f) \rightarrow \text{PRODH:PRODL}$												
Status Affected:	None												
Encoding:	<table border="1"><tr><td>0011</td><td>0100</td><td>ffff</td><td>ffff</td></tr></table>				0011	0100	ffff	ffff					
0011	0100	ffff	ffff										
Description:	<p>An unsigned multiplication is carried out between the contents of WREG and the register file location 'f'. The 16-bit result is stored in the PRODH:PRODL register pair. PRODH contains the high byte.</p> <p>Both WREG and 'f' are unchanged.</p> <p>None of the status flags are affected.</p> <p>Note that neither overflow nor carry is possible in this operation. A zero result is possible but not detected.</p>												
Words:	1												
Cycles:	1

Decode	Read register 'f'	Process Data	Write registers PRODH: PRODL										

Example: MULWF REG

Before Instruction

WREG = 0xC4
 REG = 0xB5
 PRODH = ?
 PRODL = ?

After Instruction

WREG = 0xC4
 REG = 0xB5
 PRODH = 0x8A
 PRODL = 0x94

PIC17C75X

NEGW		Negate W					
Syntax:	[<i>label</i>] NEGW f,s						
Operands:	0 ≤ F ≤ 255 s ∈ [0,1]						
Operation:	$\overline{WREG} + 1 \rightarrow (f);$ $\overline{WREG} + 1 \rightarrow s$						
Status Affected:	OV, C, DC, Z						
Encoding:	<table border="1"><tr><td>0010</td><td>110s</td><td>ffff</td><td>ffff</td></tr></table>			0010	110s	ffff	ffff
0010	110s	ffff	ffff				
Description:	WREG is negated using two's complement. If 's' is 0 the result is placed in WREG and data memory location 'f'. If 's' is 1 the result is placed only in data memory location 'f'.						
Words:	1						
Cycles:	1						
Q Cycle Activity:							
Q1	Q2	Q3	Q4				
Decode	Read register 'f'	Process Data	Write register 'f' and other specified register				

Example: NEGW REG,0

Before Instruction
WREG = 0011 1010 [0x3A],
REG = 1010 1011 [0xAB]

After Instruction
WREG = 1100 0111 [0xC6]
REG = 1100 0111 [0xC6]

NOP		No Operation						
Syntax:	[<i>label</i>] NOP							
Operands:	None							
Operation:	No operation							
Status Affected:	None							
Encoding:	<table border="1"><tr><td>0000</td><td>0000</td><td>0000</td><td>0000</td></tr></table>				0000	0000	0000	0000
0000	0000	0000	0000					
Description:	No operation.							
Words:	1							
Cycles:	1							
Q Cycle Activity:								
	Q1	Q2	Q3	Q4				
	Decode	No operation	No operation	No operation				

Example:

None.

RETFIE Return from Interrupt

Syntax: [*label*] RETFIE

Operands: None

Operation: TOS → (PC);
0 → GLINTD;
PCLATH is unchanged.

Status Affected: GLINTD

Encoding:

0000	0000	0000	0101
------	------	------	------

Description: Return from Interrupt. Stack is POP'ed and Top of Stack (TOS) is loaded in the PC. Interrupts are enabled by clearing the GLINTD bit. GLINTD is the global interrupt disable bit (CPUSTA<4>).

Words: 1

Cycles: 2

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	No operation	Clear GLINTD	POP PC from stack
No operation	No operation	No operation	No operation

Example: RETFIE

After Interrupt

PC = TOS
GLINTD = 0

RETLW Return Literal to WREG

Syntax: [*label*] RETLW k

Operands: $0 \leq k \leq 255$

Operation: k → (WREG); TOS → (PC);
PCLATH is unchanged

Status Affected: None

Encoding:

1011	0110	kkkk	kkkk
------	------	------	------

Description: WREG is loaded with the eight bit literal 'k'. The program counter is loaded from the top of the stack (the return address). The high address latch (PCLATH) remains unchanged.

Words: 1

Cycles: 2

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Process Data	POP PC from stack, Write to WREG
No operation	No operation	No operation	No operation

Example:

```
CALL TABLE ; WREG contains table
               ; offset value
               ; WREG now has
               ; table value
:
TABLE
  ADDWF PC    ; WREG = offset
  RETLW k0    ; Begin table
  RETLW k1    ;
  :
  RETLW kn    ; End of table
```

Before Instruction

WREG = 0x07

After Instruction

WREG = value of k7

RETURN

Return from Subroutine

Syntax: [label] RETURN

Operands: None

Operation: TOS → PC;

Status Affected: None

Encoding:

0000	0000	0000	0010
------	------	------	------

Description: Return from subroutine. The stack is popped and the top of the stack (TOS) is loaded into the program counter.

Words: 1

Cycles: 2

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	No operation	Process Data	POP PC from stack
No operation	No operation	No operation	No operation

Example: RETURN

After Interrupt
PC = TOS

RLCF

Rotate Left f through Carry

Syntax: [label] RLCF f,d

Operands: 0 ≤ f ≤ 255
d ∈ [0,1]

Operation: f<n> → d<n+1>;
f<7> → C;
C → d<0>

Status Affected: C

Encoding:

0001	101d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are rotated one bit to the left through the Carry Flag. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is stored back in register 'f'.

C

← register f ←

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: RLCF REG,0

Before Instruction

REG = 1110 0110

C = 0

After Instruction

REG = 1110 0110

WREG = 1100 1100

C = 1

RLNCF Rotate Left f (no carry)

Syntax: [*label*] RLNCF f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $f_{<n>} \rightarrow d_{<n+1>};$
 $f_{<7>} \rightarrow d_{<0>}$

Status Affected: None

Encoding:

0010	001d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are rotated one bit to the left. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is stored back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: RLNCF REG, 1

Before Instruction

C = 0
 REG = 1110 1011

After Instruction

C =
 REG = 1101 0111

RRCF Rotate Right f through Carry

Syntax: [*label*] RRCF f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $f_{<n>} \rightarrow d_{<n-1>};$
 $f_{<0>} \rightarrow C;$
 $C \rightarrow d_{<7>}$

Status Affected: C

Encoding:

0001	100d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are rotated one bit to the right through the Carry Flag. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: RRCF REG1, 0

Before Instruction

REG1 = 1110 0110
 C = 0

After Instruction

REG1 = 1110 0110
 WREG = 0111 0011
 C = 0

RRNCF Rotate Right f (no carry)

Syntax: [*label*] RRNCF f,d

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $f \langle n \rangle \rightarrow d \langle n-1 \rangle$;
 $f \langle 0 \rangle \rightarrow d \langle 7 \rangle$

Status Affected: None

Encoding:

0010	000d	ffff	ffff
------	------	------	------

Description: The contents of register 'f' are rotated one bit to the right. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example 1: RRNCF REG, 1

Before Instruction

WREG = ?

REG = 1101 0111

After Instruction

WREG = 0

REG = 1110 1011

Example 2: RRNCF REG, 0

Before Instruction

WREG = ?

REG = 1101 0111

After Instruction

WREG = 1110 1011

REG = 1101 0111

SETF Set f

Syntax: [*label*] SETF f,s

Operands: $0 \leq f \leq 255$
 $s \in [0,1]$

Operation: $FFh \rightarrow f$;
 $FFh \rightarrow d$

Status Affected: None

Encoding:

0010	101s	ffff	ffff
------	------	------	------

Description: If 's' is 0, both the data memory location 'f' and WREG are set to FFh. If 's' is 1 only the data memory location 'f' is set to FFh.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write register 'f' and other specified register

Example1: SETF REG, 0

Before Instruction

REG = 0xDA

WREG = 0x05

After Instruction

REG = 0xFF

WREG = 0xFF

Example2: SETF REG, 1

Before Instruction

REG = 0xDA

WREG = 0x05

After Instruction

REG = 0xFF

WREG = 0x05

SLEEP		Enter SLEEP mode						
Syntax:	[<i>label</i>] SLEEP							
Operands:	None							
Operation:	00h → WDT; 0 → WDT postscaler; 1 → \overline{TO} ; 0 → \overline{PD}							
Status Affected:	\overline{TO} , \overline{PD}							
Encoding:	<table border="1"><tr><td>0000</td><td>0000</td><td>0000</td><td>0011</td></tr></table>				0000	0000	0000	0011
0000	0000	0000	0011					
Description:	<p>The power-down status bit (\overline{PD}) is cleared. The time-out status bit (\overline{TO}) is set. Watchdog Timer and its prescaler are cleared.</p> <p>The processor is put into SLEEP mode with the oscillator stopped.</p>							
Words:	1							
Cycles:	1							

Q Cycle Activity:	Q1	Q2	Q3	Q4
	Decode	No operation	Process Data	Go to sleep

Example: SLEEP

Before Instruction

\overline{TO} = ?

\overline{PD} = ?

After Instruction

\overline{TO} = 1†

\overline{PD} = 0

† If WDT causes wake-up, this bit is cleared

SUBLW	Subtract WREG from Literal				
Syntax:	[<i>label</i>] SUBLW k				
Operands:	$0 \leq k \leq 255$				
Operation:	$k - (WREG) \rightarrow (WREG)$				
Status Affected:	OV, C, DC, Z				
Encoding:	<table><tr><td>1011</td><td>0010</td><td>kkkk</td><td>kkkk</td></tr></table>	1011	0010	kkkk	kkkk
1011	0010	kkkk	kkkk		
Description:	WREG is subtracted from the eight bit literal 'k'. The result is placed in WREG.				
Words:	1				
Cycles:	1				

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read literal 'k'	Process Data	Write to WREG

Example 1: SUBLW 0x02

Before Instruction

WREG = 1

C = ?

After Instruction

WREG = 1

C = 1 ; result is positive

Z = 0

Example 2:

Before Instruction

WREG = 2

C = ?

After Instruction

WREG = 0

C = 1 ; result is zero

Z = 1

Example 3:

Before Instruction

WREG = 3

C = ?

After Instruction

WREG = FF ; (2's complement)

C = 0 ; result is negative

Z = 1

SUBWF Subtract WREG from f

Syntax: `[label] SUBWF f,d`

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) - (W) \rightarrow (\text{dest})$

Status Affected: OV, C, DC, Z

Encoding:

0000	010d	ffff	ffff
------	------	------	------

Description: Subtract WREG from register 'f' (2's complement method). If 'd' is 0 the result is stored in WREG. If 'd' is 1 the result is stored back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example 1: `SUBWF REG1, 1`

Before Instruction

REG1 = 3
WREG = 2
C = ?

After Instruction

REG1 = 1
WREG = 2
C = 1 ; result is positive
Z = 0

Example 2:

Before Instruction

REG1 = 2
WREG = 2
C = ?

After Instruction

REG1 = 0
WREG = 2
C = 1 ; result is zero
Z = 1

Example 3:

Before Instruction

REG1 = 1
WREG = 2
C = ?

After Instruction

REG1 = FF
WREG = 2
C = 0 ; result is negative
Z = 0

SUBWFB Subtract WREG from f with Borrow

Syntax: `[label] SUBWFB f,d`

Operands: $0 \leq f \leq 255$
 $d \in [0,1]$

Operation: $(f) - (W) - \overline{C} \rightarrow (\text{dest})$

Status Affected: OV, C, DC, Z

Encoding:

0000	001d	ffff	ffff
------	------	------	------

Description: Subtract WREG and the carry flag (borrow) from register 'f' (2's complement method). If 'd' is 0 the result is stored in WREG. If 'd' is 1 the result is stored back in register 'f'.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example 1: `SUBWFB REG1, 1`

Before Instruction

REG1 = 0x19 (0001 1001)
WREG = 0x0D (0000 1101)
C = 1

After Instruction

REG1 = 0x0C (0000 1011)
WREG = 0x0D (0000 1101)
C = 1 ; result is positive
Z = 0

Example2: `SUBWFB REG1,0`

Before Instruction

REG1 = 0x1B (0001 1011)
WREG = 0x1A (0001 1010)
C = 0

After Instruction

REG1 = 0x1B (0001 1011)
WREG = 0x00
C = 1 ; result is zero
Z = 1

Example3: `SUBWFB REG1,1`

Before Instruction

REG1 = 0x03 (0000 0011)
WREG = 0x0E (0000 1101)
C = 1

After Instruction

REG1 = 0xF5 (1111 0100) [2's comp]
WREG = 0x0E (0000 1101)
C = 0 ; result is negative
Z = 0

SWAPF	Swap f				
Syntax:	[<i>label</i>] SWAPF f,d				
Operands:	$0 \leq f \leq 255$ $d \in [0,1]$				
Operation:	$f<3:0> \rightarrow \text{dest}<7:4>;$ $f<7:4> \rightarrow \text{dest}<3:0>$				
Status Affected:	None				
Encoding:	<table><tr><td>0001</td><td>110d</td><td>ffff</td><td>ffff</td></tr></table>	0001	110d	ffff	ffff
0001	110d	ffff	ffff		
Description:	The upper and lower nibbles of register 'f' are exchanged. If 'd' is 0 the result is placed in WREG. If 'd' is 1 the result is placed in register 'f'.				
Words:	1				
Cycles:	1				
Q Cycle Activity:					

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write to destination

Example: SWAPF REG, 0

Before Instruction

REG = 0x53

After Instruction

REG = 0x35

TABLRD	Table Read				
Syntax:	[<i>label</i>] TABLRD t,i,f				
Operands:	$0 \leq f \leq 255$ $i \in [0,1]$ $t \in [0,1]$				
Operation:	If $t = 1$, TBLATH $\rightarrow f$; If $t = 0$, TBLATL $\rightarrow f$; Prog Mem (TBLPTR) \rightarrow TBLAT; If $i = 1$, TBLPTR + 1 \rightarrow TBLPTR				
Status Affected:	None				
Encoding:	<table><tr><td>1010</td><td>10ti</td><td>ffff</td><td>ffff</td></tr></table>	1010	10ti	ffff	ffff
1010	10ti	ffff	ffff		
Description:	1. A byte of the table latch (TBLAT)				

Words: 1

Cycles: 2 (3 cycle if f = PCL)

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register TBLATH or TBLATL	Process Data	Write register 'f'
No operation	No operation (Table Pointer on Address bus)	No operation	No operation (OE goes low)

TABLRD Table Read

Example1: TABLRD 1, 1, REG ;

Before Instruction

REG = 0x53
TBLATH = 0xAA
TBLATL = 0x55
TBLPTR = 0xA356
MEMORY(TBLPTR) = 0x1234

After Instruction (table write completion)

REG = 0xAA
TBLATH = 0x12
TBLATL = 0x34
TBLPTR = 0xA357
MEMORY(TBLPTR) = 0x5678

Example2: TABLRD 0, 0, REG ;

Before Instruction

REG = 0x53
TBLATH = 0xAA
TBLATL = 0x55
TBLPTR = 0xA356
MEMORY(TBLPTR) = 0x1234

After Instruction (table write completion)

REG = 0x55
TBLATH = 0x12
TBLATL = 0x34
TBLPTR = 0xA356
MEMORY(TBLPTR) = 0x1234

TABLWT Table Write

Syntax: [label] TABLWT t,i,f

Operands: $0 \leq f \leq 255$
 $i \in [0,1]$
 $t \in [0,1]$

Operation: If $t = 0$,
f → TBLATL;
If $t = 1$,
f → TBLATH;
TBLAT → Prog Mem
(TBLPTR);
If $i = 1$,
TBLPTR + 1 → TBLPTR

Status Affected: None

Encoding:

1010	11ti	ffff	ffff
------	------	------	------

Description:

- Load value in 'f' into 16-bit table latch (TBLAT)
If $t = 0$: load into low byte;
If $t = 1$: load into high byte
- The contents of TBLAT is written to the program memory location pointed to by TBLPTR
If TBLPTR points to external program memory location, then the instruction takes two-cycle
If TBLPTR points to an internal EPROM location, then the instruction is terminated when an interrupt is received.

Note: The MCLR/VPP pin must be at the programming voltage for successful programming of internal memory.
If $\overline{\text{MCLR}}/\text{VPP} = \text{VDD}$
the programming sequence of internal memory will be interrupted. A short write will occur (2 Tcy).
The internal memory location will not be affected.

- The TBLPTR can be automatically incremented
If $i = 0$; TBLPTR is not incremented
If $i = 1$; TBLPTR is incremented

Words: 1

Cycles: 2 (many if write is to on-chip EPROM program memory)

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register 'f'	Process Data	Write register TBLATH or TBLATL
No operation	No operation (Table Pointer on Address bus)	No operation	No operation (Table Latch on Address bus, $\overline{\text{WR}}$ goes low)

TABLWT Table Write

Example 1: TABLWT 1, 1, REG

Before Instruction

REG = 0x53
TBLATH = 0xAA
TBLATL = 0x55
TBLPTR = 0xA356
MEMORY(TBLPTR) = 0xFFFF

After Instruction (table write completion)

REG = 0x53
TBLATH = 0x53
TBLATL = 0x55
TBLPTR = 0xA357
MEMORY(TBLPTR - 1) = 0x5355

Example 2: TABLWT 0, 0, REG

Before Instruction

REG = 0x53
TBLATH = 0xAA
TBLATL = 0x55
TBLPTR = 0xA356
MEMORY(TBLPTR) = 0xFFFF

After Instruction (table write completion)

REG = 0x53
TBLATH = 0xAA
TBLATL = 0x53
TBLPTR = 0xA356
MEMORY(TBLPTR) = 0xAA53

TLRD Table Latch Read

Syntax: [label] TLRD t,f

Operands: $0 \leq f \leq 255$
 $t \in [0,1]$

Operation: If $t = 0$,
TBLATL $\rightarrow f$;
If $t = 1$,
TBLATH $\rightarrow f$

Status Affected: None

Encoding:

1010	00tx	ffff	ffff
------	------	------	------

Description: Read data from 16-bit table latch (TBLAT) into file register 'f'. Table Latch is unaffected.

If $t = 1$; high byte is read

If $t = 0$; low byte is read

This instruction is used in conjunction with TABLRD to transfer data from program memory to data memory.

Words: 1

Cycles: 1

Q Cycle Activity:

Q1	Q2	Q3	Q4
Decode	Read register TBLATH or TBLATL	Process Data	Write register 'f'

Example: TLRD t, RAM

Before Instruction

t = 0
RAM = ?
TBLAT = 0x00AF (TBLATH = 0x00)
(TBLATL = 0xAF)

After Instruction

RAM = 0xAF
TBLAT = 0x00AF (TBLATH = 0x00)
(TBLATL = 0xAF)

Before Instruction

t = 1
RAM = ?
TBLAT = 0x00AF (TBLATH = 0x00)
(TBLATL = 0xAF)

After Instruction

RAM = 0x00
TBLAT = 0x00AF (TBLATH = 0x00)
(TBLATL = 0xAF)

TLWT Table Latch Write

Syntax:	[<i>label</i>] TLWT t,f			
Operands:	$0 \leq f \leq 255$ $t \in [0,1]$			
Operation:	If $t = 0$, $f \rightarrow \text{TBLATL}$; If $t = 1$, $f \rightarrow \text{TBLATH}$			
Status Affected:	None			
Encoding:	1010	01tx	ffff	ffff
Description:	Data from file register 'f' is written into the 16-bit table latch (TBLAT). If $t = 1$; high byte is written If $t = 0$; low byte is written This instruction is used in conjunction with TABLWT to transfer data from data memory to program memory.			
Words:	1			
Cycles:	1			
Q Cycle Activity:				
	Q1	Q2	Q3	Q4
	Decode	Read register 'f'	Process Data	Write register TBLATH or TBLATL

Example: TLWT *t*, RAM

Before Instruction

t = 0
RAM = 0xB7
TBLAT = 0x0000 (TBLATH = 0x00)
 (TBLATL = 0x00)

After Instruction

RAM = 0xB7
TBLAT = 0x00B7 (TBLATH = 0x00)
 (TBLATL = 0xB7)

Before Instruction

t = 1
RAM = 0xB7
TBLAT = 0x0000 (TBLATH = 0x00)
 (TBLATL = 0x00)

After Instruction

RAM = 0xB7
TBLAT = 0xB700 (TBLATH = 0xB7)
 (TBLATL = 0x00)

TSTFSZ Test *f*, skip if 0

Syntax:	[<i>label</i>] TSTFSZ <i>f</i>			
Operands:	$0 \leq f \leq 255$			
Operation:	skip if $f = 0$			
Status Affected:	None			
Encoding:	0011	0011	ffff	ffff
Description:	If ' <i>f</i> ' = 0, the next instruction, fetched during the current instruction execution, is discarded and an NOP is executed making this a two-cycle instruction.			
Words:	1			
Cycles:	1 (2)			
Q Cycle Activity:				
	Q1	Q2	Q3	Q4
	Decode	Read register ' <i>f</i> '	Process Data	No operation
If skip:				
	Q1	Q2	Q3	Q4
	No operation	No operation	No operation	No operation

Example: HERE TSTFSZ CNT
 NZERO :
 ZERO :

Before Instruction

PC = Address(HERE)

After Instruction

If CNT = 0x00,
 PC = Address (ZERO)
If CNT \neq 0x00,
 PC = Address (NZERO)

XORLW		Exclusive OR Literal with WREG						
Syntax:	[<i>label</i>] XORLW <i>k</i>							
Operands:	$0 \leq k \leq 255$							
Operation:	(WREG) .XOR. <i>k</i> \rightarrow (WREG)							
Status Affected:	Z							
Encoding:	<table><tr><td>1011</td><td>0100</td><td>kkkk</td><td>kkkk</td></tr></table>				1011	0100	kkkk	kkkk
1011	0100	kkkk	kkkk					
Description:	The contents of WREG are XOR'ed with the 8-bit literal ' <i>k</i> '. The result is placed in WREG.							
Words:	1							
Cycles:	1							
Q Cycle Activity:								
	Q1	Q2	Q3	Q4				
	Decode	Read literal ' <i>k</i> '	Process Data	Write to WREG				

Example: XORLW 0xAF

Before Instruction

WREG = 0xB5

After Instruction

WREG = 0x1A

XORWF		Exclusive OR WREG with f						
Syntax:	[<i>label</i>] XORWF f,d							
Operands:	0 ≤ f ≤ 255 d ∈ [0,1]							
Operation:	(WREG) .XOR. (f) → (dest)							
Status Affected:	Z							
Encoding:	<table><tr><td>0000</td><td>110d</td><td>ffff</td><td>ffff</td></tr></table>				0000	110d	ffff	ffff
0000	110d	ffff	ffff					
Description:	Exclusive OR the contents of WREG with register 'f'. If 'd' is 0 the result is stored in WREG. If 'd' is 1 the result is stored back in the register 'f'.							
Words:	1							
Cycles:	1							
Q Cycle Activity:								
Q1		Q2		Q3				
Q4								
Decode		Read register 'f'		Process Data				
				Write to destination				

Example: XORWF REG, 1

Before Instruction

REG = 0xAF

WREG = 0xB5

After Instruction

REG = 0x1A

WREG = 0xB5

PIC17C75X

NOTES:

19.0 DEVELOPMENT SUPPORT

19.1 Development Tools

The PIC16/17 microcontrollers are supported with a full range of hardware and software development tools:

- PICMASTER/PICMASTER CE Real-Time In-Circuit Emulator
- ICEPIC Low-Cost PIC16C5X and PIC16CXXX In-Circuit Emulator
- PRO MATE® II Universal Programmer
- PICSTART® Plus Entry-Level Prototype Programmer
- PICDEM-1 Low-Cost Demonstration Board
- PICDEM-2 Low-Cost Demonstration Board
- PICDEM-3 Low-Cost Demonstration Board
- MPASM Assembler
- MPLAB-SIM Software Simulator
- MPLAB-C (C Compiler)
- Fuzzy logic development system (*fuzzyTECH*®-MP)

19.2 PICMASTER: High Performance Universal In-Circuit Emulator with MPLAB IDE

The PICMASTER Universal In-Circuit Emulator is intended to provide the product development engineer with a complete microcontroller design tool set for all microcontrollers in the PIC12C5XX, PIC14C000, PIC16C5X, PIC16CXXX and PIC17CXX families. PICMASTER is supplied with the MPLAB™ Integrated Development Environment (IDE), which allows editing, “make” and download, and source debugging from a single environment.

Interchangeable target probes allow the system to be easily reconfigured for emulation of different processors. The universal architecture of the PICMASTER allows expansion to support all new Microchip microcontrollers.

The PICMASTER Emulator System has been designed as a real-time emulation system with advanced features that are generally found on more expensive development tools. The PC compatible 386 (and higher) machine platform and Microsoft Windows® 3.x environment were chosen to best make these features available to you, the end user.

A CE compliant version of PICMASTER is available for European Union (EU) countries.

19.3 ICEPIC: Low-cost PIC16CXXX In-Circuit Emulator

ICEPIC is a low-cost in-circuit emulator solution for the Microchip PIC16C5X and PIC16CXXX families of 8-bit OTP microcontrollers.

ICEPIC is designed to operate on PC-compatible machines ranging from 286-AT® through Pentium™ based machines under Windows 3.x environment. ICEPIC features real time, non-intrusive emulation.

19.4 PRO MATE II: Universal Programmer

The PRO MATE II Universal Programmer is a full-featured programmer capable of operating in stand-alone mode as well as PC-hosted mode.

The PRO MATE II has programmable VDD and VPP supplies which allows it to verify programmed memory at VDD min and VDD max for maximum reliability. It has an LCD display for displaying error messages, keys to enter commands and a modular detachable socket assembly to support various package types. In stand-alone mode the PRO MATE II can read, verify or program PIC16C5X, PIC16CXXX, PIC17CXX and PIC14000 devices. It can also set configuration and code-protect bits in this mode.

19.5 PICSTART Plus Entry Level Development System

The PICSTART programmer is an easy-to-use, low-cost prototype programmer. It connects to the PC via one of the COM (RS-232) ports. MPLAB Integrated Development Environment software makes using the programmer simple and efficient. PICSTART Plus is not recommended for production programming.

PICSTART Plus supports all PIC12C5XX, PIC14000, PIC16C5X, PIC16CXXX and PIC17CXX devices with up to 40 pins. Larger pin count devices such as the PIC16C923 and PIC16C924 may be supported with an adapter socket.

19.6 PICDEM-1 Low-Cost PIC16/17 Demonstration Board

The PICDEM-1 is a simple board which demonstrates the capabilities of several of Microchip's microcontrollers. The microcontrollers supported are: PIC16C5X (PIC16C54 to PIC16C58A), PIC16C61, PIC16C62X, PIC16C71, PIC16C8X, PIC17C42, PIC17C43 and PIC17C44. All necessary hardware and software is included to run basic demo programs. The users can program the sample microcontrollers provided with the PICDEM-1 board, on a PRO MATE II or PICSTART-16B programmer, and easily test firmware. The user can also connect the PICDEM-1 board to the PICMASTER emulator and download the firmware to the emulator for testing. Additional prototype area is available for the user to build some additional hardware and connect it to the microcontroller socket(s). Some of the features include an RS-232 interface, a potentiometer for simulated analog input, push-button switches and eight LEDs connected to PORTB.

19.7 PICDEM-2 Low-Cost PIC16CXX Demonstration Board

The PICDEM-2 is a simple demonstration board that supports the PIC16C62, PIC16C64, PIC16C65, PIC16C73 and PIC16C74 microcontrollers. All the necessary hardware and software is included to run the basic demonstration programs. The user can program the sample microcontrollers provided with the PICDEM-2 board, on a PRO MATE II programmer or PICSTART-16C, and easily test firmware. The PICMASTER emulator may also be used with the PICDEM-2 board to test firmware. Additional prototype area has been provided to the user for adding additional hardware and connecting it to the microcontroller socket(s). Some of the features include a RS-232 interface, push-button switches, a potentiometer for simulated analog input, a Serial EEPROM to demonstrate usage of the I²C bus and separate headers for connection to an LCD module and a keypad.

19.8 PICDEM-3 Low-Cost PIC16CXXX Demonstration Board

The PICDEM-3 is a simple demonstration board that supports the PIC16C923 and PIC16C924 in the PLCC package. It will also support future 44-pin PLCC microcontrollers with a LCD Module. All the necessary hardware and software is included to run the basic demonstration programs. The user can program the sample microcontrollers provided with the PICDEM-3 board, on a PRO MATE II programmer or PICSTART Plus with an adapter socket, and easily test firmware. The PICMASTER emulator may also be used with the PICDEM-3 board to test firmware. Additional prototype area has been provided to the user for adding hardware and connecting it to the microcontroller socket(s). Some of the features include

an RS-232 interface, push-button switches, a potentiometer for simulated analog input, a thermistor and separate headers for connection to an external LCD module and a keypad. Also provided on the PICDEM-3 board is an LCD panel, with 4 commons and 12 segments, that is capable of displaying time, temperature and day of the week. The PICDEM-3 provides an additional RS-232 interface and Windows 3.1 software for showing the demultiplexed LCD signals on a PC. A simple serial interface allows the user to construct a hardware demultiplexer for the LCD signals. PICDEM-3 will be available in the 3rd quarter of 1996.

19.9 MPLAB Integrated Development Environment Software

The MPLAB IDE Software brings an ease of software development previously unseen in the 8-bit microcontroller market. MPLAB is a windows based application which contains:

- A full featured editor
- Three operating modes
 - editor
 - emulator
 - simulator
- A project manager
- Customizable tool bar and key mapping
- A status bar with project information
- Extensive on-line help

MPLAB allows you to:

- Edit your source files (either assembly or 'C')
- One touch assemble (or compile) and download to PIC16/17 tools (automatically updates all project information)
- Debug using:
 - source files
 - absolute listing file
- Transfer data dynamically via DDE (soon to be replaced by OLE)
- Run up to four emulators on the same PC

The ability to use MPLAB with Microchip's simulator allows a consistent platform and the ability to easily switch from the low cost simulator to the full featured emulator with minimal retraining due to development tools.

19.10 Assembler (MPASM)

The MPASM Universal Macro Assembler is a PC-hosted symbolic assembler. It supports all microcontroller series including the PIC12C5XX, PIC14000, PIC16C5X, PIC16CXXX, and PIC17CXX families.

MPASM offers full featured Macro capabilities, conditional assembly, and several source and listing formats. It generates various object code formats to support Microchip's development tools as well as third party programmers.

MPASM allows full symbolic debugging from PICMASTER, Microchip's Universal Emulator System.

MPASM has the following features to assist in developing software for specific use applications.

- Provides translation of Assembler source code to object code for all Microchip microcontrollers.
- Macro assembly capability.
- Produces all the files (Object, Listing, Symbol, and special) required for symbolic debug with Microchip's emulator systems.
- Supports Hex (default), Decimal and Octal source and listing formats.

MPASM provides a rich directive language to support programming of the PIC16/17. Directives are helpful in making the development of your assemble source code shorter and more maintainable.

19.11 Software Simulator (MPLAB-SIM)

The MPLAB-SIM Software Simulator allows code development in a PC host environment. It allows the user to simulate the PIC16/17 series microcontrollers on an instruction level. On any given instruction, the user may examine or modify any of the data areas or provide external stimulus to any of the pins. The input/output radix can be set by the user and the execution can be performed in; single step, execute until break, or in a trace mode.

MPLAB-SIM fully supports symbolic debugging using MPLAB-C and MPASM. The Software Simulator offers the low cost flexibility to develop and debug code outside of the laboratory environment making it an excellent multi-project software development tool.

19.12 C Compiler (MPLAB-C)

The MPLAB-C Code Development System is a complete 'C' compiler and integrated development environment for Microchip's PIC16/17 family of microcontrollers. The compiler provides powerful integration capabilities and ease of use not found with other compilers.

For easier source level debugging, the compiler provides symbol information that is compatible with the MPLAB IDE memory display (PICMASTER emulator software versions 1.13 and later).

19.13 Fuzzy Logic Development System (fuzzyTECH-MP)

fuzzyTECH-MP fuzzy logic development tool is available in two versions - a low cost introductory version, MP Explorer, for designers to gain a comprehensive working knowledge of fuzzy logic system design; and a full-featured version, *fuzzyTECH-MP*, edition for implementing more complex systems.

Both versions include Microchip's *fuzzyLAB™* demonstration board for hands-on experience with fuzzy logic systems implementation.

19.14 MP-DriveWay™ – Application Code Generator

MP-DriveWay is an easy-to-use Windows-based Application Code Generator. With MP-DriveWay you can visually configure all the peripherals in a PIC16/17 device and, with a click of the mouse, generate all the initialization and many functional code modules in C language. The output is fully compatible with Microchip's MPLAB-C C compiler. The code produced is highly modular and allows easy integration of your own code. MP-DriveWay is intelligent enough to maintain your code through subsequent code generation.

19.15 SEEVAL® Evaluation and Programming System

The SEEVAL SEEPROM Designer's Kit supports all Microchip 2-wire and 3-wire Serial EEPROMs. The kit includes everything necessary to read, write, erase or program special features of any Microchip SEEPROM product including Smart Serials™ and secure serials. The Total Endurance™ Disk is included to aid in trade-off analysis and reliability calculations. The total kit can significantly reduce time-to-market and result in an optimized system.

19.16 TrueGauge® Intelligent Battery Management

The TrueGauge development tool supports system development with the MTA11200B TrueGauge Intelligent Battery Management IC. System design verification can be accomplished before hardware prototypes are built. User interface is graphically-oriented and measured data can be saved in a file for exporting to Microsoft Excel.

19.17 KEELOQ® Evaluation and Programming Tools

KEELOQ evaluation and programming tools support Microchips HCS Secure Data Products. The HCS evaluation kit includes an LCD display to show changing codes, a decoder to decode transmissions, and a programming interface to program test transmitters.

20.0 PIC17C752/756 ELECTRICAL CHARACTERISTICS

Absolute Maximum Ratings †

Ambient temperature under bias.....	-55 to +125°C
Storage temperature	-65°C to +150°C
Voltage on VDD with respect to VSS	0 to +7.5V
Voltage on $\overline{\text{MCLR}}$ with respect to VSS (Note 2).....	-0.3V to +14V
Voltage on RA2 and RA3 with respect to VSS.....	-0.3V to +14V
Voltage on all other pins with respect to VSS	-0.3V to VDD + 0.3V
Total power dissipation (Note 1).....	1.0W
Maximum current out of VSS pin(s) - total (@ 70°C)	500 mA
Maximum current into VDD pin(s) - total (@ 70°C)	500 mA
Input clamp current, I _{IK} (V _I < 0 or V _I > VDD)	±20 mA
Output clamp current, I _{OK} (V _O < 0 or V _O > VDD)	±20 mA
Maximum output current sunk by any I/O pin (except RA2 and RA3).....	35 mA
Maximum output current sunk by RA2 or RA3 pins	60 mA
Maximum output current sourced by any I/O pin	20 mA
Maximum current sunk by PORTA and PORTB (combined).....	150 mA
Maximum current sourced by PORTA and PORTB (combined).....	100 mA
Maximum current sunk by PORTC, PORTD and PORTE (combined).....	150 mA
Maximum current sourced by PORTC, PORTD and PORTE (combined).....	100 mA
Maximum current sunk by PORTF and PORTG (combined).....	150 mA
Maximum current sourced by PORTF and PORTG (combined).....	100 mA

Note 1: Power dissipation is calculated as follows: $P_{dis} = V_{DD} \times (I_{DD} - \sum I_{OH}) + \sum \{(V_{DD} - V_{OH}) \times I_{OH}\} + \sum (V_{OL} \times I_{OL})$

Note 2: Voltage spikes below VSS at the $\overline{\text{MCLR}}$ pin, inducing currents greater than 80 mA, may cause latch-up. Thus, a series resistor of 50-100Ω should be used when applying a "low" level to the $\overline{\text{MCLR}}$ pin rather than pulling this pin directly to VSS.

† NOTICE: Stresses above those listed under "Absolute Maximum Ratings" may cause permanent damage to the device. This is a stress rating only and functional operation of the device at those or any other conditions above those indicated in the operation listings of this specification is not implied. Exposure to maximum rating conditions for extended periods may affect device reliability.

TABLE 20-1: CROSS REFERENCE OF DEVICE SPECS FOR OSCILLATOR CONFIGURATIONS AND FREQUENCIES OF OPERATION (COMMERCIAL DEVICES)

OSC	PIC17LC752-08 PIC17LC756-08	PIC17C752-25 PIC17C756-25	PIC17C752-33 PIC17C756-33	JW Devices (Ceramic Windowed Devices)

VDD: 4.5V to 6.0V IDD †: 85 µA typ. at 32 kHz IPD †: < 1 µA typ. at 5.5V Freq: 2 MHz max.	VDD: 3.0V to 6.0V IDD †: 115 µA max. at 32 kHz IPD †: 5 µA max. at 5.5V Freq: 2 MHz max.

The shaded sections indicate oscillator selections which are tested for functionality, but not for MIN/MAX specifications.

It is recommended that the user select the device type that ensures the specifications required.

† The WDT, BOR, and A/D circuitry are disabled.

20.1 DC CHARACTERISTICS: PIC17C752/756-25 (Commercial, Industrial) PIC17C752/756-33 (Commercial, Industrial)

Standard Operating Conditions (unless otherwise stated)							
DC CHARACTERISTICS							
Operating temperature							
-40°C ≤ TA ≤ +85°C for industrial and 0°C ≤ TA ≤ +70°C for commercial							
Param. No.	Sym	Characteristic	Min	Typ†	Max	Units	Conditions
D001	VDD	Supply Voltage	4.5	–	6.0	V	
D002	VDR	RAM Data Retention Voltage (Note 1)	1.5 *	–	–	V	Device in SLEEP mode
D003	VPOR	VDD start voltage to ensure internal Power-on Reset signal	–	VSS	–	V	See section on Power-on Reset for details
D004	SVDD	VDD rise rate to ensure proper operation	0.085 *	–	–	V/ms	See section on Power-on Reset for details
D005	VBOR	Brown-out Reset voltage trip point	3.6	–	4.3	V	
D006	VPORTP	Power-on reset trip point	–	1.8	–	V	VDD = VPORTP
D010	IDD	Supply Current (Note 2)	–	TBD	6 *	mA	FOSC = 4 MHz (Note 4)
D011			–	TBD	12	mA	FOSC = 8 MHz
D012			–	TBD	24 *	mA	FOSC = 16 MHz
D013			–	TBD	38	mA	FOSC = 25 MHz
D015			–	TBD	50	mA	FOSC = 33 MHz
D021	IPD	Power-down Current (Note 3)	–	< 1	5	μA	VDD = 5.5V, WDT disabled
D023	ΔIBOR	Module Differential Current BOR circuitry	–	300	500	μA	VDD = 4.5V, BODEN enabled
D024	ΔIWDT	Watchdog Timer	–	10	35	μA	VDD = 5.5V
D026	ΔIAD	A/D converter	–	1	–	μA	VDD = 5.5V, A/D not converting

* These parameters are characterized but not tested.

† Data in "Typ" column is at 5V, 25°C unless otherwise stated. These parameters are for design guidance only and are not tested.

Note 1: This is the limit to which VDD can be lowered in SLEEP mode without losing RAM data.

2: The supply current is mainly a function of the operating voltage and frequency. Other factors such as I/O pin loading and switching rate, oscillator type, internal code execution pattern, and temperature also have an impact on the current consumption.

The test conditions for all IDD measurements in active operation mode are:

OSC1 = external square wave, from rail to rail; all I/O pins tristated, pulled to VDD or VSS, T0CKI = VDD,

MCLR = VDD; WDT disabled.

Current consumed from the oscillator and I/O's driving external capacitive or resistive loads needs to be considered.

For the RC oscillator, the current through the external pull-up resistor (R) can be estimated as: $VDD / (2 \cdot R)$.

For capacitive loads, the current can be estimated (for an individual I/O pin) as $(CL \cdot VDD) \cdot f$

CL = Total capacitive load on the I/O pin; f = average frequency the I/O pin switches.

The capacitive currents are most significant when the device is configured for external execution (includes extended microcontroller mode).

3: The power down current in SLEEP mode does not depend on the oscillator type. Power-down current is measured with the part in SLEEP mode, with all I/O pins in hi-impedance state and tied to VDD and VSS.

4: For RC osc configuration, current through Rext is not included. The current through the resistor can be estimated by the formula $IR = VDD/2R_{ext}$ (mA) with Rext in kOhm.

D070	IPURB	PORTB weak pull-up current	60	200	400	μA	VPIN = VSS, RBPU = 0 4.5V ≤ VDD ≤ 6.0V

* These parameters are characterized but not tested.

† Data in "Typ" column is at 5V, 25°C unless otherwise stated. These parameters are for design guidance only and are not tested.

‡ These parameters are for design guidance only and are not tested, nor characterized.

Note 1: In RC oscillator configuration, the OSC1/CLKIN pin is a Schmitt Trigger input. It is not recommended that the PIC17CXXX devices be driven with external clock in RC mode.

2: The leakage current on the MCLR pin is strongly dependent on the applied voltage level. The specified levels represent normal operating conditions. Higher leakage current may be measured at different input voltages.

3: Negative current is defined as coming out of the pin.

4: These specifications are for the programming of the on-chip program memory EPROM through the use of the table write instructions. The complete programming specifications can be found in: PIC17C75X Programming Specifications (Literature number DS TBD).

5: The MCLR/VPP pin may be kept in this range at times other than programming, but is not recommended.

6: For TTL buffers, the better of the two specifications may be used.

PIC17C75X

D084		(RC and EC osc modes)	—	—	0.4	V	IOL = 60.0 mA, VDD = 2.5V
			—	—	0.6	V	IOL = 60.0 mA, VDD = 4.5V
			—	—	0.4	V	IOL = 1 mA, VDD = 4.5V
			—	—	0.1VDD *	V	IOL = VDD/5 mA (PIC17LC75X only)
D090	VOH	Output High Voltage (Note 3) I/O ports (except RA2 and RA3)	0.9VDD	—	—	V	IOH = -VDD/2.500 mA 4.5V ≤ VDD ≤ 6.0V
D091		with TTL buffer	0.9VDD *	—	—	V	VDD = 3.0V
D093		OSC2/CLKOUT	2.4	—	—	V	IOH = -6.0 mA, VDD = 4.5V Note 6
D094		(RC and EC osc modes)	0.9VDD *	—	—	V	IOH = -5 mA, VDD = 4.5V
						V	IOH = -VDD/5 mA (PIC17LC75X only)
D150	VOD	Open Drain High Voltage	—	—	12	V	RA2 and RA3 pins only Pulled-up to externally applied voltage
D100	Cosc2	Capacitive Loading Specs on Output Pins OSC2/CLKOUT pin	—	—	25 ‡	pF	In EC or RC osc modes when OSC2 pin is outputting CLKOUT. external clock is used to drive OSC1.
D101	CIO	All I/O pins and OSC2 (in RC mode)	—	—	50 ‡	pF	
D102	CAD	System Interface Bus (PORTC, PORTD and PORTE)	—	—	50 ‡	pF	In Microprocessor or Extended Microcontroller mode

* These parameters are characterized but not tested.

† Data in "Typ" column is at 5V, 25°C unless otherwise stated. These parameters are for design guidance only and are not tested.

‡ These parameters are for design guidance only and are not tested, nor characterized.

Note 1: In RC oscillator configuration, the OSC1/CLKIN pin is a Schmitt Trigger input. It is not recommended that the PIC17CXXX devices be driven with external clock in RC mode.

2: The leakage current on the MCLR pin is strongly dependent on the applied voltage level. The specified levels represent normal operating conditions. Higher leakage current may be measured at different input voltages.

3: Negative current is defined as coming out of the pin.

4: These specifications are for the programming of the on-chip program memory EPROM through the use of the table write instructions. The complete programming specifications can be found in: PIC17C75X Programming Specifications (Literature number DS TBD).

5: The MCLR/VPP pin may be kept in this range at times other than programming, but is not recommended.

6: For TTL buffers, the better of the two specifications may be used.

Standard Operating Conditions (unless otherwise stated)							
DC CHARACTERISTICS							
Operating temperature -40°C ≤ TA ≤ +40°C							
Operating voltage VDD range as described in Section 20.1							
Param. No.	Sym	Characteristic	Min	Typ†	Max	Units	Conditions
Internal Program Memory Programming Specs (Note 4)							
D110	VPP	Voltage on MCLR/VPP pin	12.75	—	13.25	V	Note 5 Terminated via internal/external interrupt or a reset
D111	VDDP	Supply voltage during programming	4.75	5.0	5.25	V	
D112	IPP	Current into MCLR/VPP pin	—	25 ‡	50 ‡	mA	
D113	IDDP	Supply current during programming	—	—	30 ‡	mA	
D114	TPROG	Programming pulse width	100	—	1000	µs	

* These parameters are characterized but not tested.

† Data in "Typ" column is at 5V, 25°C unless otherwise stated. These parameters are for design guidance only and are not tested.

‡ These parameters are for design guidance only and are not tested, nor characterized.

Note 1: In RC oscillator configuration, the OSC1/CLKIN pin is a Schmitt Trigger input. It is not recommended that the PIC17CXX devices be driven with external clock in RC mode.

2: The leakage current on the MCLR pin is strongly dependent on the applied voltage level. The specified levels represent normal operating conditions. Higher leakage current may be measured at different input voltages.

3: Negative current is defined as coming out of the pin.

4: These specifications are for the programming of the on-chip program memory EPROM through the use of the table write instructions. The complete programming specifications can be found in: PIC17CXX Programming Specifications (Literature number DS30139).

5: The MCLR/VPP pin may be kept in this range at times other than programming, but is not recommended.

6: For TTL buffers, the better of the two specifications may be used.

Note 1: When using the Table Write for internal programming, the device temperature must be less than 40°C.

Note 2: For In-circuit Serial Programming (ISR), refer to the device programming specification.

20.4 Timing Parameter Symbolology

The timing parameter symbols have been created following one of the following formats:

1. TppS2ppS
2. TppS
3. Tcc:ST (I²C specifications only)
4. Ts (I²C specifications only)

T		T	
F	Frequency	T	Time

Lowercase symbols (pp) and their meanings:

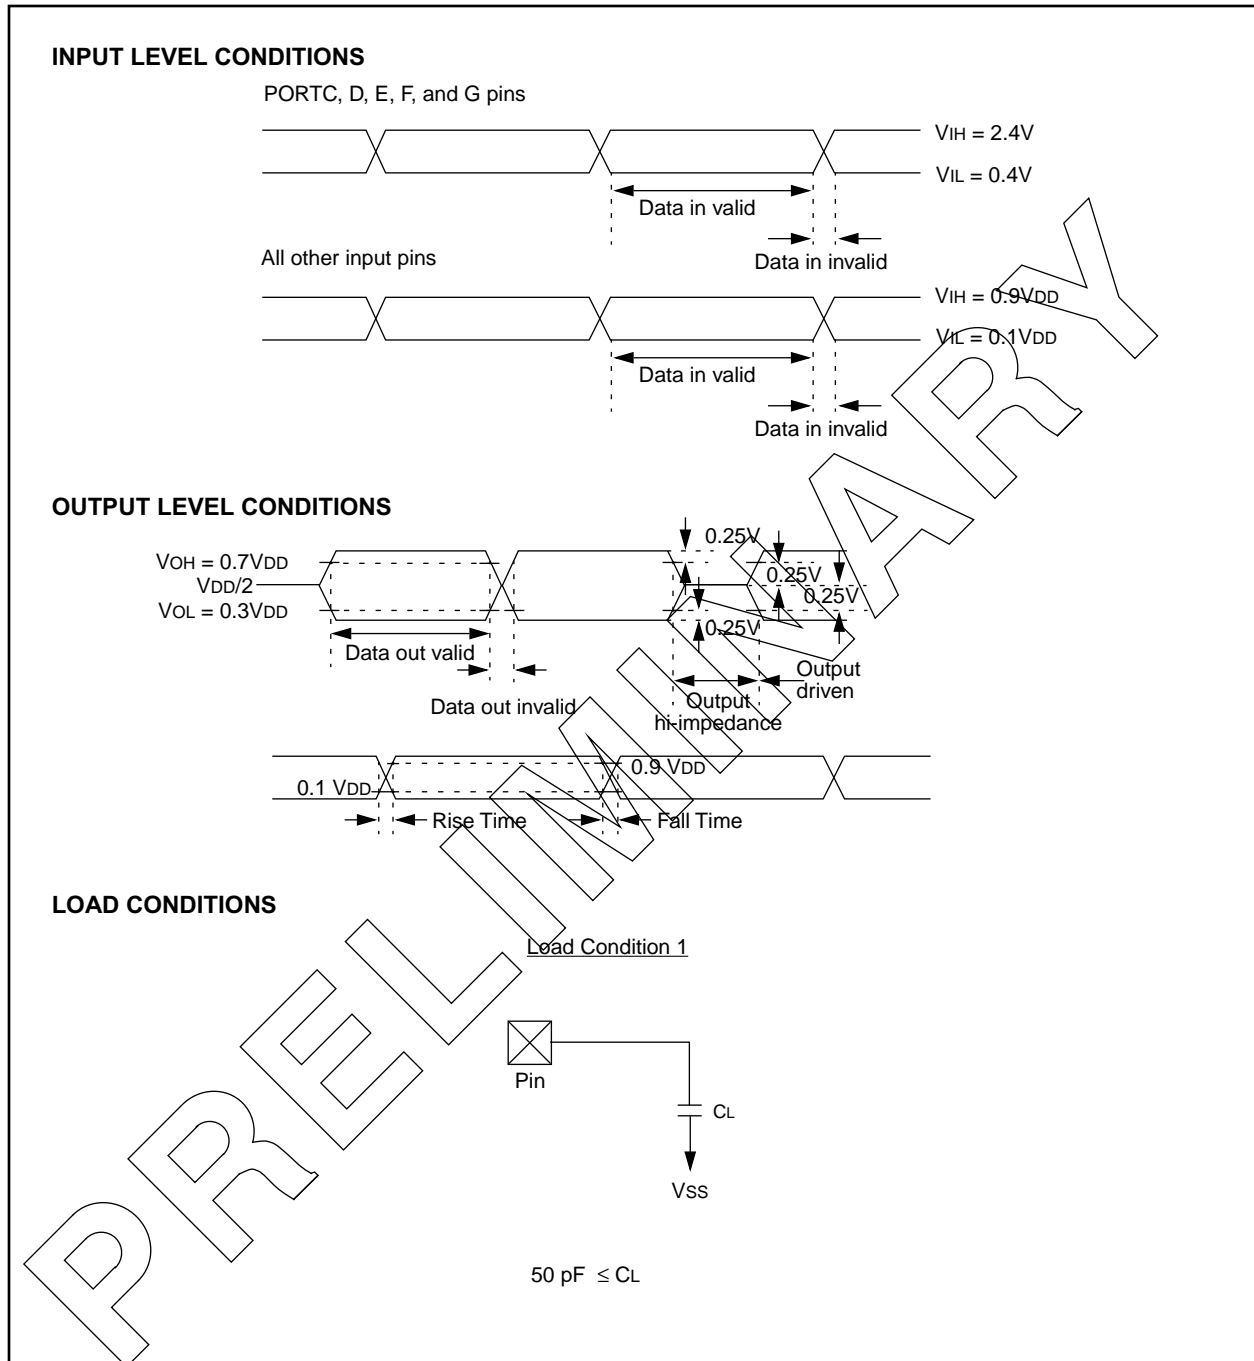

pp			
ad	Address/Data	ost	Oscillator Start-Up Timer
al	ALE	pwrt	Power-Up Timer
cc	Capture1 and Capture2	rb	PORTB
ck	CLKOUT or clock	rd	\overline{RD}
dt	Data in	rw	\overline{RD} or \overline{WR}
in	INT pin	t0	T0CKI
io	I/O port	t123	TCLK12 and TCLK3
mc	\overline{MCLR}	wdt	Watchdog Timer
oe	\overline{OE}	wr	\overline{WR}
os	OSC1		

Uppercase symbols and their meanings:

S			
D	Driven	L	Low
E	Edge	P	Period
F	Fall	R	Rise
H	High	V	Valid
I	Invalid (Hi-impedance)	Z	Hi-impedance

FIGURE 20-1: PARAMETER MEASUREMENT INFORMATION

All timings are measure between high and low measurement points as indicated in the figures below.

20.5 Timing Diagrams and Specifications

FIGURE 20-2: EXTERNAL CLOCK TIMING

TABLE 20-2: EXTERNAL CLOCK TIMING REQUIREMENTS

Param. No.	Sym	Characteristic	Min	Typ†	Max	Units	Conditions
	Fosc	External CLKIN Frequency (Note 1)	DC	—	8	MHz	EC osc mode - 08 devices (8 MHz devices)
			DC	—	25	MHz	- 25 devices (25 MHz devices)
			DC	—	33	MHz	- 33 devices (33 MHz devices)
		Oscillator Frequency (Note 1)	DC	—	4	MHz	RC osc mode
1	Tosc	External CLKIN Period (Note 1)	1	—	8	MHz	XT osc mode - 08 devices (8 MHz devices)
			1	—	25	MHz	- 25 devices (25 MHz devices)
			1	—	33	MHz	- 33 devices (33 MHz devices)
		Oscillator Period (Note 1)	DC	—	2	MHz	LF osc mode
2	Tcy	Instruction Cycle Time (Note 1)	125	—	—	ns	EC osc mode - 08 devices (8 MHz devices)
			40	—	—	ns	- 25 devices (25 MHz devices)
			30.3	—	—	ns	- 33 devices (33 MHz devices)
		Oscillator Period (Note 1)	250	—	—	ns	RC osc mode
3	TosL, TosH	Clock in (OSC1) high or low time	125	—	1,000	ns	XT osc mode - 08 devices (8 MHz devices)
			40	—	1,000	ns	- 25 devices (25 MHz devices)
			30.3	—	1,000	ns	- 33 devices (33 MHz devices)
		Clock in (OSC1) rise or fall time	500	—	—	ns	LF osc mode
4	TosR, TosF	Clock in (OSC1) rise or fall time	121.2	4/Fosc	DC	ns	
3	TosL, TosH	Clock in (OSC1) high or low time	10 ‡	—	—	ns	EC oscillator
4	TosR, TosF	Clock in (OSC1) rise or fall time	—	—	5 ‡	ns	EC oscillator

† Data in "Typ" column is at 5V, 25°C unless otherwise stated. These parameters are for design guidance only and are not tested.

‡ These parameters are for design guidance only and are not tested, nor characterized.

Note 1: Instruction cycle period (Tcy) equals four times the input oscillator time base period. All specified values are based on characterization data for that particular oscillator type under standard operating conditions with the device executing code. Exceeding these specified limits may result in an unstable oscillator operation and/or higher than expected current consumption. All devices are tested to operate at "min." values with an external clock applied to the OSC1/CLKIN pin. When an external clock input is used, the "max." cycle time limit is "DC" (no clock) for all devices.

FIGURE 20-3: CLKOUT AND I/O TIMING

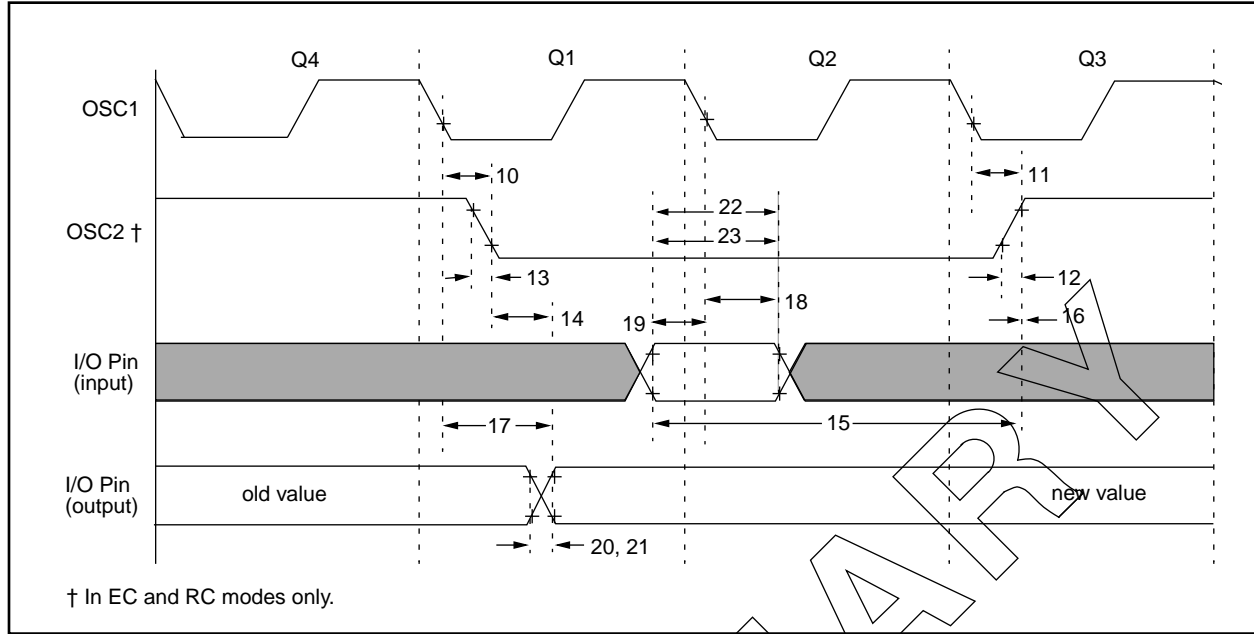

TABLE 20-3: CLKOUT AND I/O TIMING REQUIREMENTS

Param. No.	Sym	Characteristic	Min	Typ†	Max	Units	Conditions
10	TosL2ckL	OSC1↓ to CLKOUT↓	—	15 ‡	30 ‡	ns	Note 1
11	TosL2ckH	OSC1↓ to CLKOUT↑	—	15 ‡	30 ‡	ns	Note 1
12	TckR	CLKOUT rise time	—	5 ‡	15 ‡	ns	Note 1
13	TckF	CLKOUT fall time	—	5 ‡	15 ‡	ns	Note 1
14	TckH2ioV	CLKOUT ↑ to Port out valid	—	—	0.5TCY + 20 ‡	ns	Note 1
					0.5TCY + 50 ‡		Note 1
15	TioV2ckH	Port in valid before CLKOUT↑	0.25TCY + 25 ‡	—	—	ns	Note 1
			0.25TCY + 50 ‡	—	—		Note 1
16	TckH2ioL	Port in hold after CLKOUT↑	0 ‡	—	—	ns	Note 1
17	TosL2ioV	OSC1↓ (Q1 cycle) to Port out valid	—	—	100 ‡	ns	
18	TosL2ioL	OSC1↓ (Q2 cycle) to Port input invalid (I/O in hold time)	0 ‡	—	—	ns	
19	TioV2osL	Port input valid to OSC1↓ (I/O in setup time)	30 ‡	—	—	ns	
20	TioR	Port output rise time	—	10 ‡	35 ‡	ns	
21	TioF	Port output fall time	—	10 ‡	35 ‡	ns	
22	TinHL	INT pin high or low time	25 *	—	—	ns	
23	TrbHL	RB7:RB0 change INT high or low time	25 *	—	—	ns	

* These parameters are characterized but not tested.

† Data in "Typ" column is at 5V, 25°C unless otherwise stated. These parameters are for design guidance only and are not tested.

‡ These parameters are for design guidance only and are not tested, nor characterized.

Note 1: Measurements are taken in EC Mode where CLKOUT output is 4 x TOSC.

FIGURE 20-4: RESET, WATCHDOG TIMER, OSCILLATOR START-UP TIMER, POWER-UP TIMER, AND BROWN-OUT RESET TIMING

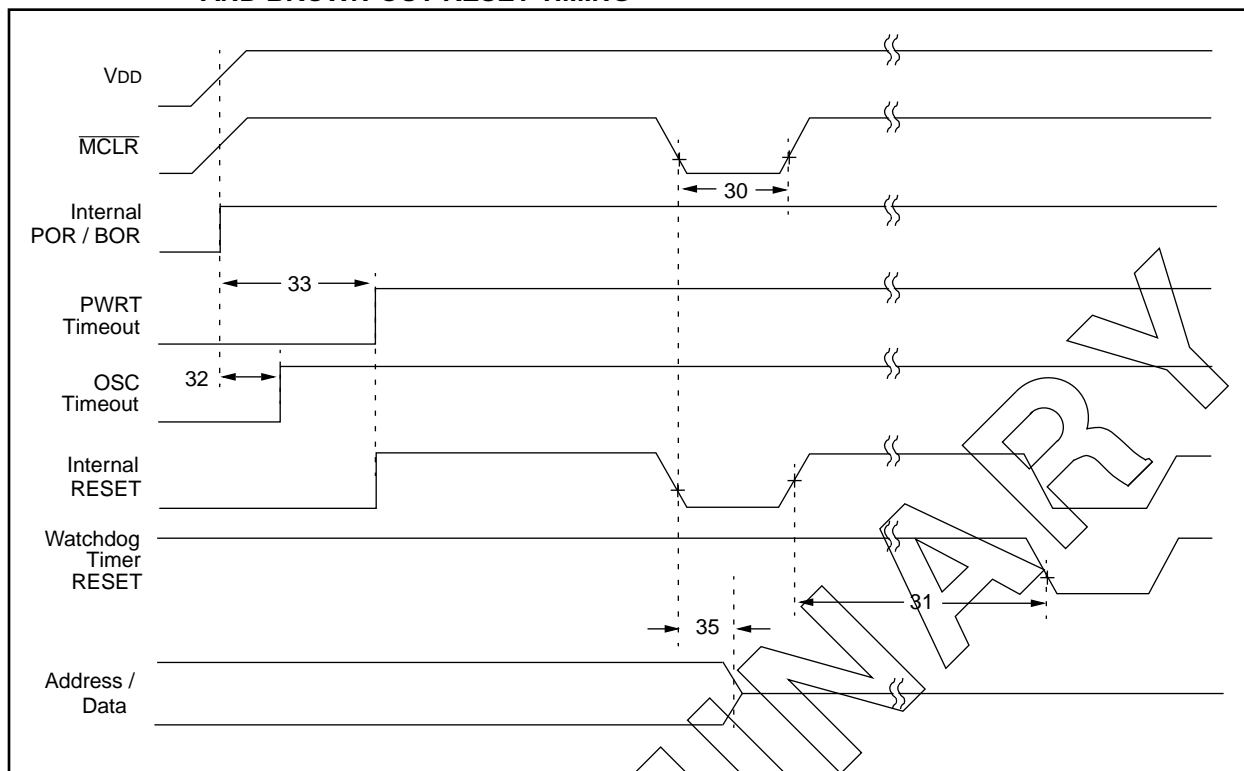

TABLE 20-4: RESET, WATCHDOG TIMER, OSCILLATOR START-UP TIMER, POWER-UP TIMER, AND BROWN-OUT RESET REQUIREMENTS

Param. No.	Sym	Characteristic	Min	Typ†	Max	Units	Conditions
30	TmCL	MCLR Pulse Width (low)	100 *	—	—	ns	VDD = 5V
31	TWDT	Watchdog Timer Time-out Period (Prescale = 1)	5 *	12	25 *	ms	VDD = 5V

* Characterized but not tested.

§ This specification ensured by design. For the value required by the I²C specification, please refer to Figure E-11.

‡ These parameters are for design guidance only and are not tested, nor characterized.

Note 1: Maximum pin capacitance = 10 pF for all I²C pins.

2: A fast-mode I²C-bus device can be used in a standard-mode I²C-bus system, but the parameter # 107 \geq 250 ns must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCL signal. If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line.

Parameter # 102.+ # 107 = 1000 + 250 = 1250 ns (for 100 kHz-mode) before the SCL line is released.

21.0 PIC17C752/756 DC AND AC CHARACTERISTICS

The graphs and tables provided in this section are for design guidance and are not tested nor guaranteed. In some graphs or tables the data presented is outside specified operating range (e.g. outside specified VDD range). This is for information only and devices are ensured to operate properly only within the specified range.

The data presented in this section is a statistical summary of data collected on units from different lots over a period of time. "Typical" represents the mean of the distribution while "max" or "min" represents (mean + 3 σ) and (mean - 3 σ) respectively where σ is standard deviation.

22.4 Package Marking Information

68-Lead CERQUAD Windowed

Example

64-Lead TQFP

Example

68-Lead PLCC

Example

64-Lead SDIP (Shrink DIP)

Example

Legend:	MM...M	Microchip part number information
	XX...X	Customer specific information*
	AA	Year code (last 2 digits of calender year)
	BB	Week code (week of January 1 is week '01')
	C	Facility code of the plant at which wafer is manufactured. C = Chandler, Arizona, U.S.A. S = Tempe, Arizona, U.S.A.
	D ₁	Mask revision number for microcontroller
	E	Assembly code of the plant or country of origin in which part was assembled.
	Note: In the event the full Microchip part number cannot be marked on one line, it will be carried over to the next line thus limiting the number of available characters for customer specific information.	

* Standard OTP marking consists of Microchip part number, year code, week code, facility code, mask revision number, and assembly code. For OTP marking beyond this, certain price adders apply. Please check with your Microchip Sales Office. For QTP devices, any special marking adders are included in QTP price.

APPENDIX A: MODIFICATIONS

The following is the list of modifications over the PIC16CXX microcontroller family:

1. Instruction word length is increased to 16-bit. This allows larger page sizes both in program memory (8 Kwords verses 2 Kwords) and register file (256 bytes versus 128 bytes).
2. Four modes of operation: microcontroller, protected microcontroller, extended microcontroller, and microprocessor.
3. 22 new instructions.
The MOVF, TRIS and OPTION instructions have been removed.
4. Four new instructions (TLRD, TLWT, TABLRD, TABLWT) for transferring data between data memory and program memory. They can be used to "self program" the EPROM program memory.
5. Single cycle data memory to data memory transfers possible (MOVFP and MOVFP instructions). These instructions do not affect the Working register (WREG).
6. W register (WREG) is now directly addressable.
7. A PC high latch register (PCLATH) is extended to 8-bits. The PCLATCH register is now both readable and writable.
8. Data memory paging is redefined slightly.
9. DDR registers replaces function of TRIS registers.
10. Multiple Interrupt vectors added. This can decrease the latency for servicing interrupts.
11. Stack size is increased to 16 deep.
12. BSR register for data memory paging.
13. Wake up from SLEEP operates slightly differently.
14. The Oscillator Start-Up Timer (OST) and Power-Up Timer (PWRT) operate in parallel and not in series.
15. PORTB interrupt on change feature works on all eight port pins.
16. TMR0 is 16-bit plus 8-bit prescaler.
17. Second indirect addressing register added (FSR1 and FSR2). Configuration bits can select the FSR registers to auto-increment, auto-decrement, remain unchanged after an indirect address.
18. Hardware multiplier added (8 x 8 → 16-bit)
19. Peripheral modules operate slightly differently.
20. A/D has both a VREF+ and VREF-.
21. USARTs do not implement BRGH feature.
22. Oscillator modes slightly redefined.
23. Control/Status bits and registers have been placed in different registers and the control bit for globally enabling interrupts has inverse polarity.
24. In-circuit serial programming is implemented differently.

APPENDIX B: COMPATIBILITY

To convert code written for PIC16CXXX to PIC17CXXX, the user should take the following steps:

1. Remove any TRIS and OPTION instructions, and implement the equivalent code.
2. Separate the interrupt service routine into its four vectors.
3. Replace:

```
MOVF    REG1, W
```

 with:

```
MOVFP   REG1, WREG
```
4. Replace:

```
MOVF    REG1, W
```

```
MOVWF   REG2
```

 with:

```
MOVFP   REG1, REG2 ; Addr(REG1)<20h
```

 or

```
MOVFP   REG1, REG2 ; Addr(REG2)<20h
```

Note: If REG1 and REG2 are both at addresses greater than 20h, two instructions are required.

```
MOVFP   REG1, WREG ;
MOVFP   WREG, REG2 ;
```

5. Ensure that all bit names and register names are updated to new data memory map locations.
6. Verify data memory banking.
7. Verify mode of operation for indirect addressing.
8. Verify peripheral routines for compatibility.
9. Weak pull-ups are enabled on reset.

To convert code from the PIC17C42 to all the other PIC17CXXX devices, the user should take the following steps.

1. If the hardware multiply is to be used, ensure that any variables at address 18h and 19h are moved to another address.
2. Ensure that the upper nibble of the BSR was not written with a non-zero value. This may cause unexpected operation since the RAM bank is no longer 0.
3. The disabling of global interrupts has been enhanced so there is no additional testing of the GLINTD bit after a BSF CPUSTA, GLINTD instruction.

APPENDIX C: WHAT'S NEW

This is the first revision of the Data Sheet .
Nothing new at this time.

APPENDIX D: WHAT'S CHANGED

This is the first revision of the Data Sheet .
Nothing new at this time.

APPENDIX E: I²C™ OVERVIEW

This section provides an overview of the Inter-Integrated Circuit (I²C) bus, with Section 15.2 discussing the operation of the SSP module in I²C mode.

The I²C bus is a two-wire serial interface developed by the Philips Corporation. The original specification, or standard mode, was for data transfers of up to 100 Kbps. This device will communicate with fast mode devices if attached to the same bus.

The I²C interface employs a comprehensive protocol to ensure reliable transmission and reception of data. When transmitting data, one device is the "master" which initiates transfer on the bus and generates the clock signals to permit that transfer, while the other device(s) acts as the "slave." All portions of the slave protocol are implemented in the SSP module's hardware, including general call support. Table E-1 defines some of the I²C bus terminology. For additional information on the I²C interface specification, refer to the Philips document "*The I²C bus and how to use it.*" #939839340011, which can be obtained from the Philips Corporation.

In the I²C interface protocol each device has an address. When a master wishes to initiate a data transfer, it first transmits the address of the device that it wishes to "talk" to. All devices "listen" to see if this is their address. Within this address, a bit specifies if the master wishes to read-from/write-to the slave device. The master and slave are always in opposite modes (transmitter/receiver) of operation during a data transfer. That is they can be thought of as operating in either of these two relations:

- Master-transmitter and Slave-receiver
- Slave-transmitter and Master-receiver

In both cases the master generates the clock signal.

The output stages of the clock (SCL) and data (SDA) lines must have an open-drain or open-collector in order to perform the wired-AND function of the bus.

External pull-up resistors are used to ensure a high level when no device is pulling the line down. The number of devices that may be attached to the I²C bus is limited only by the maximum bus loading specification of 400 pF.

E.1 Initiating and Terminating Data Transfer

During times of no data transfer (idle time), both the clock line (SCL) and the data line (SDA) are pulled high through the external pull-up resistors. The START and STOP conditions determine the start and stop of data transmission. The START condition is defined as a high to low transition of the SDA when the SCL is high. The STOP condition is defined as a low to high transition of the SDA when the SCL is high. Figure E-1 shows the START and STOP conditions. The master generates these conditions for starting and terminating data transfer. Due to the definition of the START and STOP conditions, when data is being transmitted, the SDA line can only change state when the SCL line is low.

FIGURE E-1: START AND STOP CONDITIONS

TABLE E-1: I²C BUS TERMINOLOGY

Term	Description
Transmitter	The device that sends the data to the bus.
Receiver	The device that receives the data from the bus.
Master	The device which initiates the transfer, generates the clock and terminates the transfer.
Slave	The device addressed by a master.
Multi-master	More than one master device in a system. These masters can attempt to control the bus at the same time without corrupting the message.
Arbitration	Procedure that ensures that only one of the master devices will control the bus. This ensure that the transfer data does not get corrupted.
Synchronization	Procedure where the clock signals of two or more devices are synchronized.

E.2 ADDRESSING I²C DEVICES

There are two address formats. The simplest is the 7-bit address format with a R/W bit (Figure E-2). The more complex is the 10-bit address with a R/W bit (Figure E-3). For 10-bit address format, two bytes must be transmitted with the first five bits specifying this to be a 10-bit address.

FIGURE E-2: 7-BIT ADDRESS FORMAT

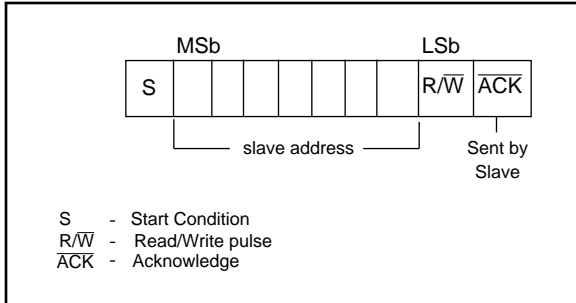

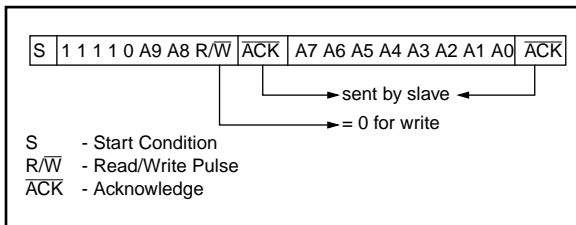

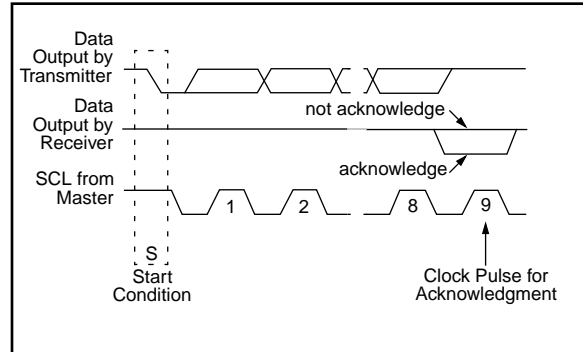

FIGURE E-3: I²C 10-BIT ADDRESS FORMAT

E.3 Transfer Acknowledge

All data must be transmitted per byte, with no limit to the number of bytes transmitted per data transfer. After each byte, the slave-receiver generates an acknowledge bit (ACK) (Figure E-4). When a slave-receiver doesn't acknowledge the slave address or received data, the master must abort the transfer. The slave must leave SDA high so that the master can generate the STOP condition (Figure E-1).

FIGURE E-4: SLAVE-RECEIVER ACKNOWLEDGE

If the master is receiving the data (master-receiver), it generates an acknowledge signal for each received byte of data, except for the last byte. To signal the end of data to the slave-transmitter, the master does not generate an acknowledge (not acknowledge). The slave then releases the SDA line so the master can generate the STOP condition. The master can also generate the STOP condition during the acknowledge pulse for valid termination of data transfer.

If the slave needs to delay the transmission of the next byte, holding the SCL line low will force the master into a wait state. Data transfer continues when the slave releases the SCL line. This allows the slave to move the received data or fetch the data it needs to transfer before allowing the clock to start. This wait state technique can also be implemented at the bit level, Figure E-5. The slave will inherently stretch the clock, when it is a transmitter, but will not when it is a receiver. The slave will have to clear the CKP bit to enable clock stretching when it is a receiver.

FIGURE E-5: DATA TRANSFER WAIT STATE

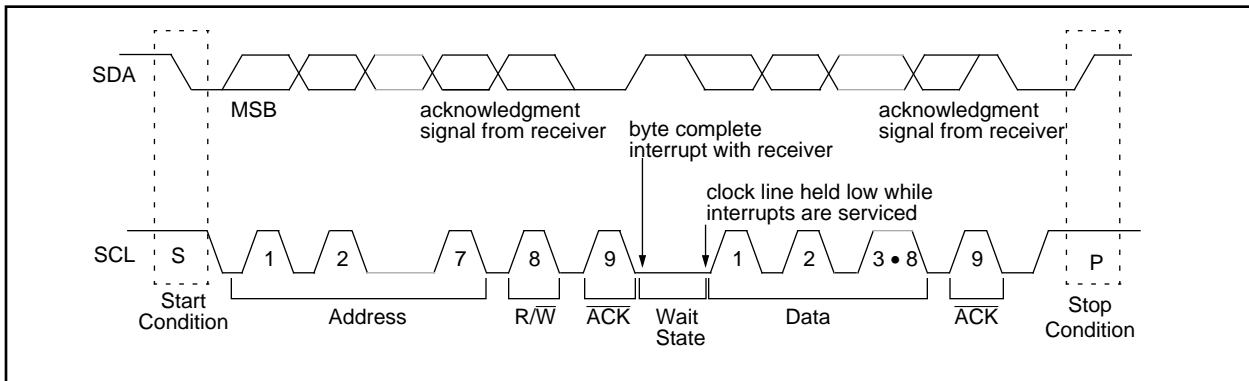

Figure E-6 and Figure E-7 show Master-transmitter and Master-receiver data transfer sequences.

When a master does not wish to relinquish the bus (by generating a STOP condition), a repeated START condition (Sr) must be generated. This condition is identical to the start condition (S) (SDA goes high-to-low while

SCL is high), but occurs after a data transfer acknowledge pulse (not the bus-free state). This allows a master to send "commands" to the slave and then receive the requested information or to address a different slave device. This sequence is shown in Figure E-8.

FIGURE E-6: MASTER-TRANSMITTER SEQUENCE

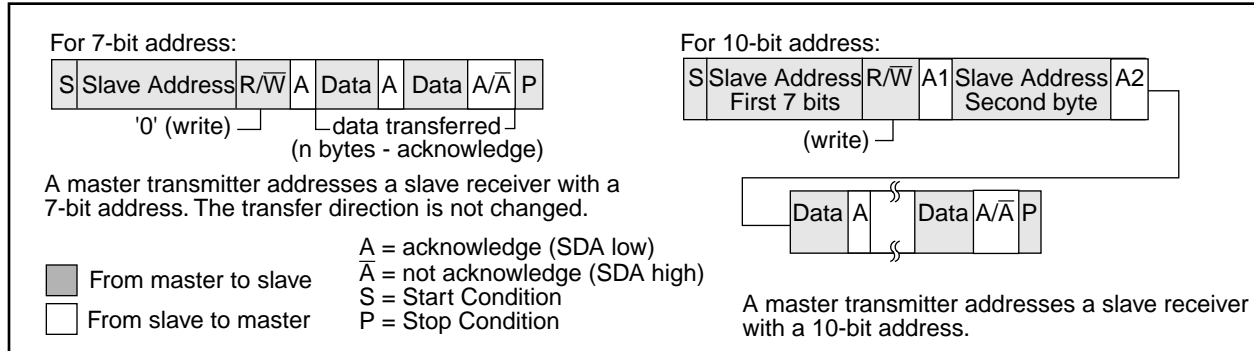

FIGURE E-7: MASTER-RECEIVER SEQUENCE

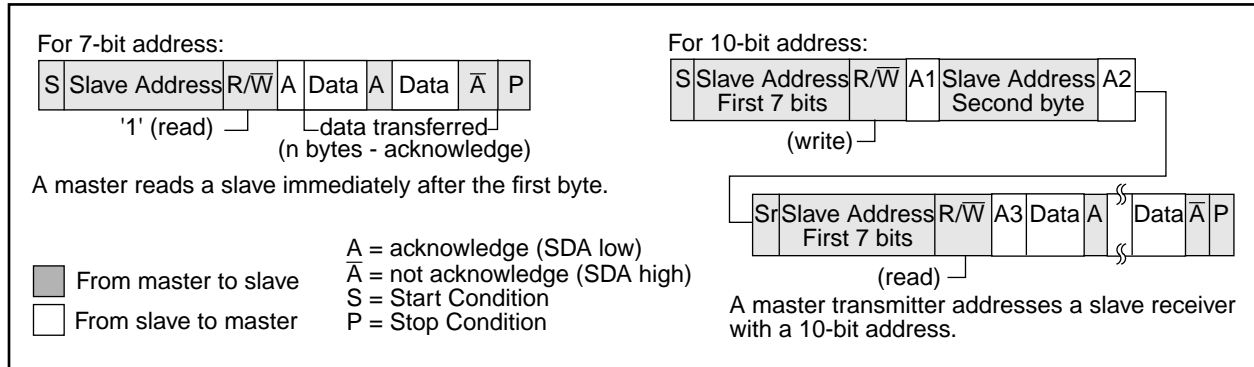

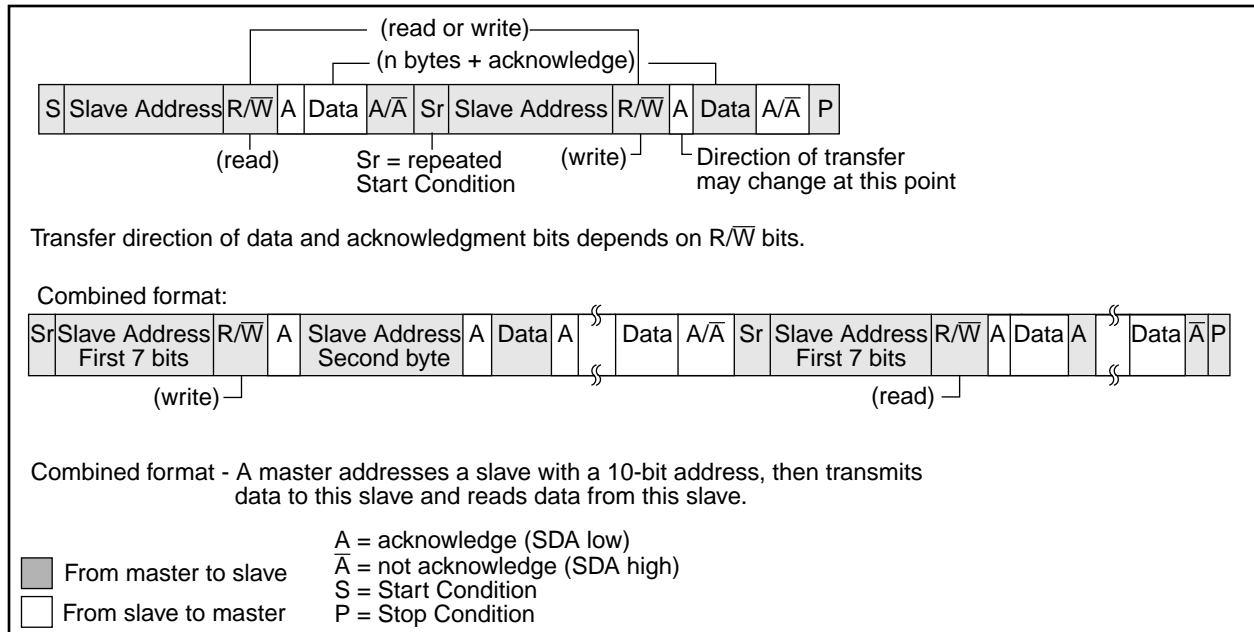

FIGURE E-8: COMBINED FORMAT

E.4 Multi-master

The I²C protocol allows a system to have more than one master. This is called multi-master. When two or more masters try to transfer data at the same time, arbitration and synchronization occur.

E.4.1 ARBITRATION

Arbitration takes place on the SDA line, while the SCL line is high. The master which transmits a high when the other master transmits a low loses arbitration (Figure E-9), and turns off its data output stage. A master which lost arbitration can generate clock pulses until the end of the data byte where it lost arbitration. When the master devices are addressing the same device, arbitration continues into the data.

FIGURE E-9: MULTI-MASTER ARBITRATION (TWO MASTERS)

Masters that also incorporate the slave function, and have lost arbitration must immediately switch over to slave-receiver mode. This is because the winning master-transmitter may be addressing it.

Arbitration is not allowed between:

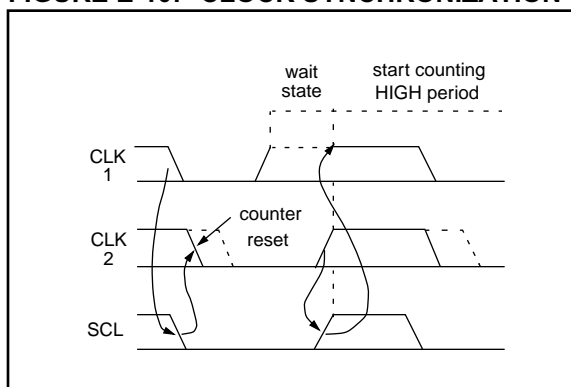

- A repeated START condition
- A STOP condition and a data bit
- A repeated START condition and a STOP condition

Care needs to be taken to ensure that these conditions do not occur.

E.5 Clock Synchronization

Clock synchronization occurs after the devices have started arbitration. This is performed using a wired-AND connection to the SCL line. A high to low transition on the SCL line causes the concerned devices to start counting off their low period. Once a device clock has gone low, it will hold the SCL line low until its SCL high state is reached. The low to high transition of this clock may not change the state of the SCL line, if another device clock is still within its low period. The SCL line is held low by the device with the longest low period. Devices with shorter low periods enter a high wait-state, until the SCL line comes high. When the SCL line comes high, all devices start counting off their high periods. The first device to complete its high period will pull the SCL line low. The SCL line high time is determined by the device with the shortest high period, Figure E-10.

FIGURE E-10: CLOCK SYNCHRONIZATION

E.6 I²C Timing Specifications

Table E-2 (Figure E-11) and Table E-3 (Figure E-12) show the timing specifications as required by the Philips specification for I²C. For additional information please refer to to Section 15.2 and Section 20.5.

FIGURE E-11: I²C BUS START/STOP BITS TIMING SPECIFICATION

TABLE E-2: I²C BUS START/STOP BITS TIMING SPECIFICATION

Microchip Parameter No.	Sym	Characteristic		Min	Typ	Max	Units	Conditions
90	TSU:STA	START condition	100 kHz mode	4700	—	—	ns	Only relevant for repeated START condition
		Setup time	400 kHz mode	600	—	—		
91	THD:STA	START condition	100 kHz mode	4000	—	—	ns	After this period the first clock pulse is generated
		Hold time	400 kHz mode	600	—	—

		Setup time	400 kHz mode	600	—	—		
93	THD:STO	STOP condition	100 kHz mode	4000 ‡	—	—	ns	
		Hold time	400 kHz mode	600 ‡	—	—		

FIGURE E-12: I²C BUS DATA TIMING SPECIFICATION

TABLE E-3: I²C BUS DATA TIMING SPECIFICATION

Microchip Parameter No.	Sym	Characteristic	Min	Max	Units	Conditions
100	THIGH	Clock high time	100 kHz mode	4.0	—	μs
			400 kHz mode	0.6	—	μs
101	TLOW	Clock low time	100 kHz mode	4.7	—	μs
			400 kHz mode	1.3	—	μs
102	TR	SDA and SCL rise time	100 kHz mode	—	1000	ns
			400 kHz mode	20 + 0.1Cb	300	ns Cb is specified to be from 10 to 400 pF
103	TF	SDA and SCL fall time	100 kHz mode	—	300	ns
			400 kHz mode	20 + 0.1Cb	300	ns Cb is specified to be from 10 to 400 pF
90	TSU:STA	START condition setup time	100 kHz mode	4.7	—	μs
			400 kHz mode	0.6	—	μs
91	THD:STA	START condition hold time	100 kHz mode	4.0	—	μs
			400 kHz mode	0.6	—	μs
106	THD:DAT	Data input hold time	100 kHz mode	0	—	ns
			400 kHz mode	0	0.9	μs
107	TSU:DAT	Data input setup time	100 kHz mode	250	—	ns
			400 kHz mode	100	—	ns
92	TSU:STO	STOP condition setup time	100 kHz mode	4.7	—	μs
			400 kHz mode	0.6	—	μs
109	TAA	Output valid from clock	100 kHz mode	—	3500	ns
			400 kHz mode	—	1000	ns
110	TBUF	Bus free time	100 kHz mode	4.7	—	μs
			400 kHz mode	1.3	—	μs
D102	Cb	Bus capacitive loading	—	400	pF	Time the bus must be free before a new transmission can start

Note 1: As a transmitter, the device must provide this internal minimum delay time to bridge the undefined region (min. 300 ns) of the falling edge of SCL to avoid unintended generation of START or STOP conditions.

- 2: A fast-mode I²C-bus device can be used in a standard-mode I²C-bus system, but the requirement tsu;DAT ≥ 250 ns must then be met. This will automatically be the case if the device does not stretch the LOW period of the SCL signal. If such a device does stretch the LOW period of the SCL signal, it must output the next data bit to the SDA line
 TR max.+tsu;DAT = 1000 + 250 = 1250 ns (according to the standard-mode I²C bus specification) before the SCL line is released.

- Note 1: SFR file locations 10h - 17h are banked. The lower nibble of the BSR specifies the bank. All unbanked SFRs ignore the Bank Select Register (BSR) bits.
- 2: General Purpose Registers (GPR) locations 20h - FFh, 120h - 1FFh, 220h - 2FFh, and 320h - 3FFh are banked. The upper nibble of the BSR specifies this bank. All other GPRs ignore the Bank Select Register (BSR) bits.
- 3: These RAM banks are not implemented on the PIC17C752. Reading any register in this bank reads '0's.

FIGURE F-2: ALUSTA REGISTER (ADDRESS: 04h, UNBANKED)

R/W - 1	R/W - 1	R/W - 1	R/W - 1	R/W - x	R/W - x	R/W - x	R/W - x
FS3	FS2	FS1	FS0	OV	Z	DC	C
bit7							bit0

R = Readable bit
W = Writable bit
-n = Value at POR reset
(x = unknown)

bit 7-6: **FS3:FS2**: FSR1 Mode Select bits
00 = Post auto-decrement FSR1 value
01 = Post auto-increment FSR1 value
1x = FSR1 value does not change

bit 5-4: **FS1:FS0**: FSR0 Mode Select bits
00 = Post auto-decrement FSR0 value
01 = Post auto-increment FSR0 value
1x = FSR0 value does not change

bit 3: **OV**: Overflow bit
This bit is used for signed arithmetic (2's complement). It indicates an overflow of the 7-bit magnitude, which causes the sign bit (bit7) to change state.
1 = Overflow occurred for signed arithmetic, (in this arithmetic operation)
0 = No overflow occurred

bit 2: **Z**: Zero bit
1 = The result of an arithmetic or logic operation is zero
0 = The results of an arithmetic or logic operation is not zero

bit 1: **DC**: Digit carry/borrow bit
For ADDWF and ADDLW instructions.
1 = A carry-out from the 4th low order bit of the result occurred
0 = No carry-out from the 4th low order bit of the result
Note: For borrow the polarity is reversed.

bit 0: **C**: carry/borrow bit
For ADDWF and ADDLW instructions.
1 = A carry-out from the most significant bit of the result occurred
Note that a subtraction is executed by adding the two's complement of the second operand. For rotate (RRCF, RLCF) instructions, this bit is loaded with either the high or low order bit of the source register.
0 = No carry-out from the most significant bit of the result
Note: For borrow the polarity is reversed.

INTEDG	T0SE	T0CS	PS3	T0PS2	T0PS1	T0PS0	—
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented, reads as '0'
-n = Value at POR reset

bit 7: **INTEDG:** RA0/INT Pin Interrupt Edge Select bit
This bit selects the edge upon which the interrupt is detected.
1 = Rising edge of RA0/INT pin generates interrupt
0 = Falling edge of RA0/INT pin generates interrupt

bit 6: **T0SE:** Timer0 Clock Input Edge Select bit
This bit selects the edge upon which TMR0 will increment.
When T0CS = 0 (External Clock)
1 = Rising edge of RA1/T0CKI pin increments TMR0 and/or generates a T0CKIF interrupt
0 = Falling edge of RA1/T0CKI pin increments TMR0 and/or generates a T0CKIF interrupt
When T0CS = 1 (Internal Clock)
Don't care

bit 5: **T0CS:** Timer0 Clock Source Select bit
This bit selects the clock source for Timer0.
1 = Internal instruction clock cycle (TCY)
0 = External clock input on the T0CKI pin

bit 4-1: **T0PS3:T0PS0:** Timer0 Prescale Selection bits
These bits select the prescale value for Timer0.

T0PS3:T0PS0	Prescale Value
0000	1:1
0001	1:2
0010	1:4
0011	1:8
0100	1:16
0101	1:32
0110	1:64
0111	1:128
1xxx	1:256

bit 0: **Unimplemented:** Read as '0'

FIGURE F-4: CPUSTA REGISTER (ADDRESS: 06h, UNBANKED)

—	—	STKAV	GLINTD	TO	PD	POR	BOR
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, Read as '0'
- n = Value at POR reset

bit 7-6: **Unimplemented:** Read as '0'

bit 5: **STKAV:** Stack Available bit
This bit indicates that the 4-bit stack pointer value is Fh, or has rolled over from Fh → 0h (stack overflow).
1 = Stack is available
0 = Stack is full, or a stack overflow may have occurred (Once this bit has been cleared by a stack overflow, only a device reset will set this bit)

bit 4: **GLINTD:** Global Interrupt Disable bit
This bit disables all interrupts. When enabling interrupts, only the sources with their enable bits set can cause an interrupt.
1 = Disable all interrupts
0 = Enables all un-masked interrupts

bit 3: **TO:** WDT Time-out Status bit
1 = After power-up or by a CLRWDI instruction
0 = A Watchdog Timer time-out occurred

bit 2: **PD:** Power-down Status bit
1 = After power-up or by the CLRWDI instruction
0 = By execution of the SLEEP instruction

bit 1: **POR:** Power-on Reset Status bit
1 = No Power-on Reset occurred
0 = A Power-on Reset occurred (must be set by software after a Power-on Reset occurs)

bit 0: **BOR:** Brown-out Reset Status bit
1 = No Brown-out Reset occurred
0 = A Brown-out Reset occurred (must be set by software after a Brown-out Reset occurs)

FIGURE F-5: INTSTA REGISTER (ADDRESS: 07h, UNBANKED)

R = Readable bit
W = Writable bit
- n = Value at POR reset

bit 7: **PEIF**: Peripheral Interrupt Flag bit
This bit is the OR of all peripheral interrupt flag bits AND'ed with their corresponding enable bits.
1 = A peripheral interrupt is pending
0 = No peripheral interrupt is pending

bit 6: **T0CKIF**: External Interrupt on T0CKI Pin Flag bit
This bit is cleared by hardware, when the interrupt logic forces program execution to vector (18h).
1 = The software specified edge occurred on the RA1/T0CKI pin
0 = The software specified edge did not occur on the RA1/T0CKI pin

bit 5: **T0IF**: TMR0 Overflow Interrupt Flag bit
This bit is cleared by hardware, when the interrupt logic forces program execution to vector (10h).
1 = TMR0 overflowed
0 = TMR0 did not overflow

bit 4: **INTF**: External Interrupt on INT Pin Flag bit
This bit is cleared by hardware, when the interrupt logic forces program execution to vector (08h).
1 = The software specified edge occurred on the RA0/INT pin
0 = The software specified edge did not occur on the RA0/INT pin

bit 3: **PEIE**: Peripheral Interrupt Enable bit
This bit enables all peripheral interrupts that have their corresponding enable bits set.
1 = Enable peripheral interrupts
0 = Disable peripheral interrupts

bit 2: **T0CKIE**: External Interrupt on T0CKI Pin Enable bit
1 = Enable software specified edge interrupt on the RA1/T0CKI pin
0 = Disable interrupt on the RA1/T0CKI pin

bit 1: **T0IE**: TMR0 Overflow Interrupt Enable bit
1 = Enable TMR0 overflow interrupt
0 = Disable TMR0 overflow interrupt

bit 0: **INTE**: External Interrupt on RA0/INT Pin Enable bit
1 = Enable software specified edge interrupt on the RA0/INT pin
0 = Disable software specified edge interrupt on the RA0/INT pin

bit 7: **RBIF**: PORTB Interrupt on Change Flag bit
1 = One of the PORTB inputs changed (software must end the mismatch condition)
0 = None of the PORTB inputs have changed

bit 6: **TMR3IF**: TMR3 Interrupt Flag bit
If Capture1 is enabled (CA1/PR3 = 1)
1 = TMR3 overflowed
0 = TMR3 did not overflow
If Capture1 is disabled (CA1/PR3 = 0)
1 = TMR3 value has rolled over to 0000h from equalling the period register (PR3H:PR3L) value
0 = TMR3 value has not rolled over to 0000h from equalling the period register (PR3H:PR3L) value

bit 5: **TMR2IF**: TMR2 Interrupt Flag bit
1 = TMR2 value has rolled over to 0000h from equalling the period register (PR2) value
0 = TMR2 value has not rolled over to 0000h from equalling the period register (PR2) value

bit 4: **TMR1IF**: TMR1 Interrupt Flag bit
If TMR1 is in 8-bit mode (T16 = 0)
1 = TMR1 value has rolled over to 0000h from equalling the period register (PR1) value
0 = TMR1 value has not rolled over to 0000h from equalling the period register (PR1) value
If Timer1 is in 16-bit mode (T16 = 1)
1 = TMR2:TMR1 value has rolled over to 0000h from equalling the period register (PR2:PR1) value
0 = TMR2:TMR1 value has not rolled over to 0000h from equalling the period register (PR2:PR1) value

R = Readable bit
W = Writable bit
-n = Value at POR reset

bit 7: **SSPIF**: Synchronous Serial Port (SSP) Interrupt Flag
1 = The SSP interrupt condition has occurred, and must be cleared in software before returning from the interrupt service routine. The conditions that will set this bit are:
SPI
A transmission/reception has taken place.
I²C Slave / Master
A transmission/reception has taken place.
I²C Master
The initiated start condition was completed by the SSP module.
The initiated stop condition was completed by the SSP module.
The initiated restart condition was completed by the SSP module.
The initiated acknowledge condition was completed by the SSP module.
A start condition occurred while the SSP module was idle (Multimaster system).
A stop condition occurred while the SSP module was idle (Multimaster system).
0 = An SSP interrupt condition has occurred.

bit 6: **BCLIF**: Bus Collision Interrupt Flag
1 = A bus collision has occurred in the SSP, when configured for I²C master mode
0 = No bus collision has occurred

bit 5: **ADIF**: A/D Module Interrupt Flag
1 = An A/D conversion is complete
0 = An A/D conversion is not complete

bit 4: **Unimplemented**: Read as '0'

bit 3: **CA4IF**: Capture4 Interrupt Flag
1 = Capture event occurred on RE3/CAP4 pin
0 = Capture event did not occur on RE3/CAP4 pin

bit 2: **CA3IF**: Capture3 Interrupt Flag
1 = Capture event occurred on RG4/CAP3 pin
0 = Capture event did not occur on RG4/CAP3 pin

bit 1: **TX2IF**: USART2 Transmit Interrupt Flag
1 = USART2 Transmit buffer is empty
0 = USART2 Transmit buffer is full

bit 0: **RC2IF**: USART2 Receive Interrupt Flag
1 = USART2 Receive buffer is full
0 = USART2 Receive buffer is empty

(x = unknown)

bit 7: **CSRC**: Clock Source Select bit
Synchronous mode:
1 = Master Mode (Clock generated internally from BRG)
0 = Slave mode (Clock from external source)
Asynchronous mode:
Don't care

bit 6: **TX9**: 9-bit Transmit Select bit
1 = Selects 9-bit transmission
0 = Selects 8-bit transmission

bit 5: **TXEN**: Transmit Enable bit
1 = Transmit enabled
0 = Transmit disabled
SREN/CREN overrides TXEN in SYNC mode

bit 4: **SYNC**: USART Mode Select bit
(Synchronous/Asynchronous)
1 = Synchronous mode
0 = Asynchronous mode

bit 3-2: **Unimplemented**: Read as '0'

bit 1: **TRMT**: Transmit Shift Register (TSR) Empty bit
1 = TSR empty
0 = TSR full

bit 0: **TX9D**: 9th bit of transmit data (can be used to calculated the parity in software)

**FIGURE F-11: RCSTA1 REGISTER (ADDRESS: 13h, BANK 0)

bit 7							bit 0

R = Readable bit
W = Writable bit
-n = Value at POR reset
(x = unknown)

bit 7: **SPEN:** Serial Port Enable bit
1 = Configures TX/CK and RX/DT pins as serial port pins
0 = Serial port disabled

bit 6: **RX9:** 9-bit Receive Select bit
1 = Selects 9-bit reception
0 = Selects 8-bit reception

bit 5: **SREN:** Single Receive Enable bit
This bit enables the reception of a single byte. After receiving the byte, this bit is automatically cleared.
Synchronous mode:
1 = Enable reception
0 = Disable reception
Note: This bit is ignored in synchronous slave reception.
Asynchronous mode:
Don't care

bit 4: **CREN:** Continuous Receive Enable bit
This bit enables the continuous reception of serial data.
Asynchronous mode:
1 = Enable continuous reception
0 = Disables continuous reception
Synchronous mode:
1 = Enables continuous reception until CREN is cleared (CREN overrides SREN)
0 = Disables continuous reception

bit 3: **Unimplemented:** Read as '0'

bit 2: **FERR:** Framing Error bit
1 = Framing error (Updated by reading RCREG)
0 = No framing error

bit 1: **OERR:** Overrun Error bit
1 = Overrun (Cleared by clearing CREN)
0 = No overrun error

bit 0: **RX9D:** 9th bit of receive data (can be the software calculated parity bit)

FIGURE F-12: TCON1 REGISTER (ADDRESS: 16h, BANK 3)

R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0
CA2ED1	CA2ED0	CA1ED1	CA1ED0	T16	TMR3CS	TMR2CS	TMR1CS
bit7							bit0

R = Readable bit
W = Writable bit
-n = Value at POR reset

bit 7-6: **CA2ED1:CA2ED0**: Capture2 Mode Select bits
00 = Capture on every falling edge
01 = Capture on every rising edge
10 = Capture on every 4th rising edge
11 = Capture on every 16th rising edge

bit 5-4: **CA1ED1:CA1ED0**: Capture1 Mode Select bits
00 = Capture on every falling edge
01 = Capture on every rising edge
10 = Capture on every 4th rising edge
11 = Capture on every 16th rising edge

bit 3: **T16**: Timer2:Timer1 Mode Select bit
1 = Timer2 and Timer1 form a 16-bit timer
0 = Timer2 and Timer1 are two 8-bit timers

bit 2: **TMR3CS**: Timer3 Clock Source Select bit
1 = TMR3 increments off the falling edge of the RB5/TCLK3 pin
0 = TMR3 increments off the internal clock

bit 1: **TMR2CS**: Timer2 Clock Source Select bit
1 = TMR2 increments off the falling edge of the RB4/TCLK12 pin
0 = TMR2 increments off the internal clock

bit 0: **TMR1CS**: Timer1 Clock Source Select bit
1 = TMR1 increments off the falling edge of the RB4/TCLK12 pin
0 = TMR1 increments off the internal clock

FIGURE F-13: TCON2 REGISTER (ADDRESS: 17h, BANK 3)

R - 0	R - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0
CA2OVF	CA1OVF	PWM2ON	PWM1ON	CA1/PR3	TMR3ON	TMR2ON	TMR1ON
bit7							bit0

R = Readable bit
W = Writable bit
-n = Value at POR reset

bit 7: **CA2OVF**: Capture2 Overflow Status bit
This bit indicates that the capture value had not been read from the capture register pair (CA2H:CA2L) before the next capture event occurred. The capture register retains the oldest unread capture value (last capture before overflow). Subsequent capture events will not update the capture register with the TMR3 value until the capture register has been read (both bytes).
1 = Overflow occurred on Capture2 register
0 = No overflow occurred on Capture2 register

bit 6: **CA1OVF**: Capture1 Overflow Status bit
This bit indicates that the capture value had not been read from the capture register pair (PR3H/CA1H:PR3L/CA1L) before the next capture event occurred. The capture register retains the oldest unread capture value (last capture before overflow). Subsequent capture events will not update the capture register with the TMR3 value until the capture register has been read (both bytes).
1 = Overflow occurred on Capture1 register
0 = No overflow occurred on Capture1 register

bit 5: **PWM2ON**: PWM2 On bit
1 = PWM2 is enabled (The RB3/PWM2 pin ignores the state of the DDRB<3> bit)
0 = PWM2 is disabled (The RB3/PWM2 pin uses the state of the DDRB<3> bit for data direction)

bit 4: **PWM1ON**: PWM1 On bit
1 = PWM1 is enabled (The RB2/PWM1 pin ignores the state of the DDRB<2> bit)
0 = PWM1 is disabled (The RB2/PWM1 pin uses the state of the DDRB<2> bit for data direction)

bit 3: **CA1/PR3**: CA1/PR3 Register Mode Select bit
1 = Enables Capture1 (PR3H/CA1H:PR3L/CA1L is the Capture1 register. Timer3 runs without a period register)
0 = Enables the Period register (PR3H/CA1H:PR3L/CA1L is the Period register for Timer3)

bit 2: **TMR3ON**: Timer3 On bit
1 = Starts Timer3
0 = Stops Timer3

bit 1: **TMR2ON**: Timer2 On bit
This bit controls the incrementing of the TMR2 register. When TMR2:TMR1 form the 16-bit timer (T16 is set), TMR2ON must be set. This allows the MSB of the timer to increment.
1 = Starts Timer2 (Must be enabled if the T16 bit (TCON1<3>) is set)
0 = Stops Timer2

bit 0: **TMR1ON**: Timer1 On bit
When T16 is set (in 16-bit Timer Mode)
1 = Starts 16-bit TMR2:TMR1
0 = Stops 16-bit TMR2:TMR1

When T16 is clear (in 8-bit Timer Mode)
1 = Starts 8-bit Timer1
0 = Stops 8-bit Timer1

FIGURE F-14: TCON3 REGISTER (ADDRESS: 16h, BANK 7)

U-0	R - 0	R - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0	R/W - 0
-	CA4OVF	CA3OVF	CA4ED1	CA4ED0	CA3ED1	CA3ED0	PWM3ON
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, Reads as '0'
-n = Value at POR reset

bit 7: **Unimplemented:** Read as '0'

bit 6: **CA4OVF:** Capture4 Overflow Status bit
This bit indicates that the capture value had not been read from the capture register pair (CA4H:CA4L) before the next capture event occurred. The capture register retains the oldest unread capture value (last capture before overflow). Subsequent capture events will not update the capture register with the TMR3 value until the capture register has been read (both bytes).
1 = Overflow occurred on Capture4 registers
0 = No overflow occurred on Capture4 registers

bit 5: **CA3OVF:** Capture3 Overflow Status bit
This bit indicates that the capture value had not been read from the capture register pair (CA3H:CA3L) before the next capture event occurred. The capture register retains the oldest unread capture value (last capture before overflow). Subsequent capture events will not update the capture register with the TMR3 value until the capture register has been read (both bytes).
1 = Overflow occurred on Capture3 registers
0 = No overflow occurred on Capture3 registers

bit 4-3: **CA4ED1:CA4ED0:** Capture4 Mode Select bits
00 = Capture on every falling edge
01 = Capture on every rising edge
10 = Capture on every 4th rising edge
11 = Capture on every 16th rising edge

bit 2-1: **CA3ED1:CA3ED0:** Capture3 Mode Select bits
00 = Capture on every falling edge
01 = Capture on every rising edge
10 = Capture on every 4th rising edge
11 = Capture on every 16th rising edge

bit 0: **PWM3ON:** PWM3 On bit
1 = PWM3 is enabled (The RG5/PWM3 pin ignores the state of the DDRG<5> bit)
0 = PWM3 is disabled (The RG5/PWM3 pin uses the state of the DDRG<5> bit for data direction)

FIGURE F-15: ADCON0 REGISTER (ADDRESS: 14h, BANK 5)

R/W-0	R/W-0	R/W-0	R/W-0	U-0	R/W-0	U-0	R/W-0
CHS3	CHS2	CHS1	CHS0	—	GO/DONE	—	ADON
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, read as '0'
- n = Value at POR reset

bit 7-4: **CHS2:CHS0**: Analog Channel Select bits

0000 = channel 0, (AN0)
0001 = channel 1, (AN1)
0010 = channel 2, (AN2)
0011 = channel 3, (AN3)
0100 = channel 4, (AN4)
0101 = channel 5, (AN5)
0110 = channel 6, (AN6)
0111 = channel 7, (AN7)
1000 = channel 8, (AN8)
1001 = channel 9, (AN9)
1010 = channel 10, (AN10)
1011 = channel 11, (AN11)
11xx = **RESERVED**, do not select

bit 3: **Unimplemented**: Read as '0'

bit 2: **GO/DONE**: A/D Conversion Status bit

If **ADON** = 1

1 = A/D conversion in progress (setting this bit starts the A/D conversion which is automatically cleared by hardware when the A/D conversion is complete)
0 = A/D conversion not in progress

bit 1: **Unimplemented**: Read as '0'

bit 0: **ADON**: A/D On bit

1 = A/D converter module is operating
0 = A/D converter module is shutoff and consumes no operating current

FIGURE F-16: ADCON1 REGISTER (ADDRESS 15h, BANK 5)

R/W-0	R/W-0	R/W-0	U-0	R/W-0	R/W-0	R/W-0	R/W-0
ADCS1	ADCS0	ADFM	—	PCFG3	PCFG2	PCFG1	PCFG0
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, read as '0'
- n = Value at POR reset

bit 7-6: **ADCS1:ADCS0:** A/D Conversion Clock Select bits
00 = Fosc/8
01 = Fosc/32
10 = Fosc/64
11 = FRC (clock derived from an internal RC oscillation)

bit 5: **ADFM:** A/D Result format select
1 = Right justified. 6 Most Significant bits of ADRESH are read as '0'.
0 = Left justified. 6 Least Significant bits of ADRESL are read as '0'.

bit 4: **Unimplemented:** Read as '0'

bit 3-0: **PCFG3:PCFG1:** A/D Port Configuration Control bits

PCFG3:PCFG1	AN11	AN10	AN9	AN8	AN7	AN6	AN5	AN4	AN3	AN2	AN1	AN0
000	A	A	A	A	A	A	A	A	A	A	A	A
001	A	A	A	A	D	A	A	A	A	A	A	A
010	A	A	A	A	D	D	A	A	A	A	A	A
011	A	A	A	A	D	D	D	A	A	A	A	A

110	D	D	A	A	D	D	D	D	D	D	A	A
111	D	D	D	D	D	D	D	D	D	D	D	D

A = Analog input D = Digital I/O

bit 0: **PCFG0:** A/D Voltage Reference Select bit
1 = A/D reference is the VREF+ and VREF- pins
0 = A/D reference is AVDD and AVSS

Note:When this bit is set, ensure that the A/D voltage reference specifications are met.

FIGURE F-17: SSPSTAT: SYNC SERIAL PORT STATUS REGISTER (ADDRESS: 13h, BANK 6)

R/W-0	R/W-0	R-0	R-0	R-0	R-0	R-0	R-0
SMP	CKE	D/A	P	S	R/W	UA	BF
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, read as '0'
- n = Value at POR reset

bit 7: **SMP**: SPI data input sample phase
SPI Master Mode
1 = Input data sampled at end of data output time
0 = Input data sampled at middle of data output time
SPI Slave Mode
SMP must be cleared when SPI is used in slave mode
In I²C master or slave mode:
1 = Slew rate control disabled for standard speed mode (100 kHz and 1 MHz)
0 = Slew rate control enabled for high speed mode (400 kHz)

bit 6: **CKE**: SPI Clock Edge Select (Figure 15-8, Figure 15-11, and Figure 15-12)
CKP = 0
1 = Data transmitted on rising edge of SCK
0 = Data transmitted on falling edge of SCK
CKP = 1
1 = Data transmitted on falling edge of SCK
0 = Data transmitted on rising edge of SCK

bit 5: **D/A**: Data/Address bit (I²C slave mode only)
1 = Indicates that the last byte received or transmitted was data
0 = Indicates that the last byte received or transmitted was address

bit 4: **P**: Stop bit (I²C mode only. This bit is cleared when the SSP module is disabled, SSPEN is cleared)
1 = Indicates that a stop bit has been detected last (this bit is '0' on RESET)
0 = Stop bit was not detected last

bit 3: **S**: Start bit (I²C mode only. This bit is cleared when the SSP module is disabled, SSPEN is cleared)
1 = Indicates that a start bit has been detected last (this bit is '0' on RESET)
0 = Start bit was not detected last

bit 2: **R/W**: Read/Write bit information (I²C mode only)
This bit holds the R/W bit information following the last address match. This bit is only valid from the address match to the next start bit, stop bit, or $\overline{\text{ACK}}$ bit.
In I²C slave mode:
1 = Read
0 = Write
In I²C master mode:
1 = Transmit is in progress
0 = Transmit is not in progress. Or'ing this bit with SAE, RCE, SPE, or AKE will indicate if the SSP is in IDLE mode.

bit 1: **UA**: Update Address (10-bit I²C mode only)
1 = Indicates that the user needs to update the address in the SSPADD register
0 = Address does not need to be updated

bit 0: **BF**: Buffer Full Status bit
Receive (SPI and I²C modes)
1 = Receive complete, SSPBUF is full
0 = Receive not complete, SSPBUF is empty
Transmit (I²C mode only)
1 = Data Transmit in progress (does not include $\overline{\text{ACK}}$ and stop bits), SSPBUF is full
0 = Data Transmit complete (does not include $\overline{\text{ACK}}$ and stop bits), SSPBUF is empty

FIGURE F-18: SSPCON1: SYNC SERIAL PORT CONTROL REGISTER (ADDRESS 11h, BANK 6)

R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0
WCOL	SSPOV	SSPEN	CKP	SSPM3	SSPM2	SSPM1	SSPM0
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, read as '0'
- n = Value at POR reset

bit 7: **WCOL**: Write Collision Detect bit
Master Mode:
1 = A write to the SSPBUF register was attempted while the I²C conditions were not valid for a transmission to be started
0 = No collision
Slave Mode:
1 = The SSPBUF register is written while it is still transmitting the previous word (must be cleared in software)
0 = No collision

bit 6: **SSPOV**: Receive Overflow Indicator bit
In SPI mode
1 = A new byte is received while the SSPBUF register is still holding the previous data. In case of overflow, the data in SSPSR is lost. Overflow can only occur in slave mode. The user must read the SSPBUF, even if only transmitting data, to avoid setting overflow. In master mode the overflow bit is not set since each new reception (and transmission) is initiated by writing to the SSPBUF register.
0 = No overflow
In I²C mode
1 = A byte is received while the SSPBUF register is still holding the previous byte. SSPOV is a "don't care" in transmit mode. SSPOV must be cleared in software in either mode.
0 = No overflow

bit 5: **SSPEN**: Synchronous Serial Port Enable bit
In SPI mode
1 = Enables serial port and configures SCK, SDO, and SDI as serial port pins
0 = Disables serial port and configures these pins as I/O port pins
In I²C mode
1 = Enables the serial port and configures the SDA and SCL pins as serial port pins
0 = Disables serial port and configures these pins as I/O port pins
Note: In both modes, when enabled, these pins must be properly configured as input or output.

bit 4: **CKP**: Clock Polarity Select bit
In SPI mode
1 = Idle state for clock is a high level
0 = Idle state for clock is a low level
In I²C slave mode
SCK release control
1 = Enable clock
0 = Holds clock low (clock stretch) (Used to ensure data setup time)
In I²C master mode
Unused in this mode

bit 3-0: **SSPM3:SSPM0**: Synchronous Serial Port Mode Select bits
0000 = SPI master mode, clock = FOSC/4
0001 = SPI master mode, clock = FOSC/16
0010 = SPI master mode, clock = FOSC/64
0011 = SPI master mode, clock = TMR2 output/2
0100 = SPI slave mode, clock = SCK pin. \overline{SS} pin control enabled.
0101 = SPI slave mode, clock = SCK pin. \overline{SS} pin control disabled. \overline{SS} can be used as I/O pin
0110 = I²C slave mode, 7-bit address
0111 = I²C slave mode, 10-bit address
1000 = I²C master mode, clock = FOSC / (4 * (SSPADD+1))
1xx1 = Reserved
1x1x = Reserved

FIGURE F-19: SSPCON2: SYNC SERIAL PORT CONTROL REGISTER2 (ADDRESS 12h, BANK 6)

R/W-0	R-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0	R/W-0
GCEN	ACKSTAT	ACKDT	ACKEN	RCEN	PEN	RSEN	SEN
bit7							bit0

R = Readable bit
W = Writable bit
U = Unimplemented bit, Read as '0'
- n = Value at POR reset

bit 7: **GCEN:** General Call Enable bit (In I²C slave mode only)
1 = Enable interrupt when a general call address is received in the SSPSR.
0 = General call address disabled.

bit 6: **ACKSTAT:** Acknowledge Status bit (In I²C master mode only)
In master transmit mode:
1 = Acknowledge was not received from slave
0 = Acknowledge was received from slave

bit 5: **ACKDT:** Acknowledge Data bit (In I²C master mode only)
In master receive mode:
Value that will be transmitted when the user initiates an Acknowledge sequence at the end of a receive.
1 = Not Acknowledge
0 = Acknowledge

bit 4: **ACKEN:** Acknowledge Sequence Enable bit (In I²C master mode only).
In master receive mode:
1 = Initiate Acknowledge sequence on SDA and SCL pins, and transmit AKD data bit. Automatically cleared by hardware.
0 = Acknowledge sequence idle
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

bit 3: **RCEN:** Receive enable bit (In I²C master mode only).
1 = Enables Receive mode for I²C
0 = Receive idle
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

bit 2: **PEN:** Stop Condition Enable bit (In I²C master mode only).
SCK release control
1 = Initiate Stop condition on SDA and SCL pins. Automatically cleared by hardware.
0 = Stop condition idle
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

bit 1: **RSEN:** Restart Condition Enabled bit (In I²C master mode only)
1 = Initiate Restart condition on SDA and SCL pins. Automatically cleared by hardware.
0 = Restart condition idle.
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

bit 0: **SEN:** Start Condition Enabled bit (In I²C master mode only)
1 = Initiate Start condition on SDA and SCL pins. Automatically cleared by hardware.
0 = Start condition idle.
Note: If the I²C module is not in the idle mode, this bit may not be set (no spooling), and the SSPBUF may not be written (or writes to the SSPBUF are disabled).

PIC17C75X

NOTES:

APPENDIX G: PIC16/17 MICROCONTROLLERS

G.1 PIC12CXXX Family of Devices

		PIC12C508	PIC12C509	PIC12C671	PIC12C672
Clock	Maximum Frequency of Operation (MHz)	4	4	4	4

All PIC16/17 Family devices have Power-on Reset, selectable Watchdog Timer, selectable code protect and high I/O current capability.

PIN COMPATIBILITY

Devices that have the same package type and VDD, Vss and MCLR pin locations are said to be pin compatible. This allows these different devices to operate in the same socket. Compatible devices may only requires minor software modification to allow proper operation in the application socket (ex., PIC16C56 and PIC16C61 devices). Not all devices in the same package size are pin compatible; for example, the PIC16C62 is compatible with the PIC16C63, but not the PIC16C55.

Pin compatibility does not mean that the devices offer the same features. As an example, the PIC16C54 is pin compatible with the PIC16C71, but does not have an A/D converter, weak pull-ups on PORTB, or interrupts.

TABLE G-1: PIN COMPATIBLE DEVICES

Pin Compatible Devices	Package
PIC12C508, PIC12C509, PIC12C671, PIC12C672	8-pin
PIC16C154, PIC16CR154, PIC16C156, PIC16CR156, PIC16C158, PIC16CR158, PIC16C52, PIC16C54, PIC16C54A, PIC16CR54A, PIC16C56, PIC16C58A, PIC16CR58A, PIC16C61, PIC16C554, PIC16C556, PIC16C558 PIC16C620, PIC16C621, PIC16C622 PIC16C641, PIC16C642, PIC16C661, PIC16C662 PIC16C710, PIC16C71, PIC16C711, PIC16C715 PIC16F83, PIC16CR83, PIC16F84A, PIC16CR84	18-pin, 20-pin
PIC16C55, PIC16C57, PIC16CR57B	28-pin
PIC16CR62, PIC16C62A, PIC16C63, PIC16C72, PIC16C73A	28-pin
PIC16CR64, PIC16C64A, PIC16C65A, PIC16C74A	40-pin
PIC17CR42, PIC17C42A, PIC17C43, PIC17CR43, PIC17C44	40-pin
PIC16C923, PIC16C924	64/68-pin
PIC17C756, PIC17C752	64/68-pin

List of Equations and Examples

Example 3-1: Signed Math.....	9
Example 4-1: Instruction Pipeline Flow	19
Example 6-1: Saving STATUS and WREG in RAM (Simple)	37
Example 6-2: Saving STATUS and WREG in RAM (Nested)	38
Example 7-1: Indirect Addressing	51
Example 8-1: Table Write	58
Example 8-2: Table Read	60
Example 9-1: 8 x 8 Unsigned Multiply Routine	61
Example 9-2: 8 x 8 Signed Multiply Routine	61
Equation 9-1: 16 x 16 Unsigned Multiplication Algorithm ..	62
Example 9-3: 16 x 16 Unsigned Multiply Routine	62
Equation 9-2: 16 x 16 Signed Multiplication Algorithm	63
Example 9-4: 16 x 16 Signed Multiply Routine	63
Example 10-1: Initializing PORTA.....	66
Example 10-2: Initializing PORTB.....	69
Example 10-3: Initializing PORTC	72
Example 10-4: Initializing PORTD	74
Example 10-5: Initializing PORTE.....	76
Example 10-6: Initializing PORTF.....	78
Example 10-7: Initializing PORTG	80
Example 10-8: Read Modify Write Instructions on an I/O Port	83
Example 12-1: 16-Bit Read.....	89
Example 12-2: 16-Bit Write	89
Example 13-1: Sequence to Read Capture Registers	103
Example 13-2: Writing to TMR3.....	104
Example 13-3: Reading from TMR3	104
Example 14-1: Calculating Baud Rate Error	110
Example 15-1: Loading the SSPBUF (SSPSR) Register ..	127
Equation 16-1: A/D Minimum Charging Time (For CHOLD)	170
Example 16-1: Calculating the Minimum Required Acquisition Time	171
Example 16-2: A/D Conversion.....	172

NOTES:

ON-LINE SUPPORT

Microchip provides two methods of on-line support. These are the Microchip BBS and the Microchip World Wide Web (WWW) site.

Use Microchip's Bulletin Board Service (BBS) to get current information and help about Microchip products. Microchip provides the BBS communication channel for you to use in extending your technical staff with microcontroller and memory experts.

To provide you with the most responsive service possible, the Microchip systems team monitors the BBS, posts the latest component data and software tool updates, provides technical help and embedded systems insights, and discusses how Microchip products provide project solutions.

The web site, like the BBS, is used by Microchip as a means to make files and information easily available to customers. To view the site, the user must have access to the Internet and a web browser, such as Netscape or Microsoft Explorer. Files are also available for FTP download from our FTP site.

Connecting to the Microchip Internet Web Site

The Microchip web site is available by using your favorite Internet browser to attach to:

www.microchip.com

The file transfer site is available by using an FTP service to connect to:

<ftp://ftp.futureone.com/pub/microchip>

The web site and file transfer site provide a variety of services. Users may download files for the latest Development Tools, Data Sheets, Application Notes, User's Guides, Articles and Sample Programs. A variety of Microchip specific business information is also available, including listings of Microchip sales offices, distributors and factory representatives. Other data available for consideration is:

- Latest Microchip Press Releases
- Technical Support Section with Frequently Asked Questions
- Design Tips
- Device Errata
- Job Postings
- Microchip Consultant Program Member Listing
- Links to other useful web sites related to Microchip Products

Connecting to the Microchip BBS

Connect worldwide to the Microchip BBS using either the Internet or the CompuServe® communications network.

Internet:

You can telnet or ftp to the Microchip BBS at the address: **[mchibbbs.microchip.com](telnet://mchibbbs.microchip.com)**

CompuServe Communications Network:

When using the BBS via the Compuserve Network, in most cases, a local call is your only expense. The Microchip BBS connection does not use CompuServe membership services, therefore you do not need CompuServe membership to join Microchip's BBS. There is no charge for connecting to the Microchip BBS.

The procedure to connect will vary slightly from country to country. Please check with your local CompuServe agent for details if you have a problem. CompuServe service allow multiple users various baud rates depending on the local point of access.

The following connect procedure applies in most locations.

1. Set your modem to 8-bit, No parity, and One stop (8N1). This is not the normal CompuServe setting which is 7E1.
2. Dial your local CompuServe access number.
3. Depress the **<Enter>** key and a garbage string will appear because CompuServe is expecting a 7E1 setting.
4. Type +, depress the **<Enter>** key and "Host Name:" will appear.
5. Type MCHIPBBS, depress the **<Enter>** key and you will be connected to the Microchip BBS.

In the United States, to find the CompuServe phone number closest to you, set your modem to 7E1 and dial (800) 848-4480 for 300-2400 baud or (800) 331-7166 for 9600-14400 baud connection. After the system responds with "Host Name:", type NETWORK, depress the **<Enter>** key and follow CompuServe's directions.

For voice information (or calling from overseas), you may call (614) 723-1550 for your local CompuServe number.

Microchip regularly uses the Microchip BBS to distribute technical information, application notes, source code, errata sheets, bug reports, and interim patches for Microchip systems software products. For each SIG, a moderator monitors, scans, and approves or disapproves files submitted to the SIG. No executable files are accepted from the user community in general to limit the spread of computer viruses.

Systems Information and Upgrade Hot Line

The Systems Information and Upgrade Line provides system users a listing of the latest versions of all of Microchip's development systems software products. Plus, this line provides information on how customers can receive any currently available upgrade kits. The Hot Line Numbers are:

1-800-755-2345 for U.S. and most of Canada, and
1-602-786-7302 for the rest of the world.

970301

PIC17C75X Product Identification System

To order or to obtain information, e.g., on pricing or delivery, please use the listed part numbers, and refer to the factory or the listed sales offices.

PART NO. – XX X /XX XXX				Examples	
			Pattern:	QTP, SQTP, ROM Code (factory specified) or Special Requirements. Blank for OTP and Windowed devices	a) PIC17C756 – 25/P Commercial Temp., PDIP package, 25 MHz, normal VDD limits
			Package:	P = PDIP JW = Windowed Cerdip P = PDIP (600 mil) PQ = MQFP PT = TQFP L = PLCC	b) PIC17LC756–08/PT Commercial Temp., TQFP package, 8MHz, extended VDD limits
			Temperature Range:	– = 0°C to +70°C I = –40°C to +85°C	
			Frequency Range:	08 = 8 MHz 25 = 25 MHz 33 = 33 MHz	c) PIC17C756–33I/P Industrial Temp., PDIP package, 33 MHz, normal VDD limits
			Device:	PIC17C756 : Standard VDD range PIC17C756T : (Tape and Reel) PIC17LC756 : Extended VDD range	

Sales and Support

Products supported by a preliminary Data Sheet may possibly have an errata sheet describing minor operational differences and recommended workarounds. To determine if an errata sheet exists for a particular device, please contact one of the following:

1. The Microchip Website at www.microchip.com
2. Your local Microchip sales office (see following page)
3. The Microchip Corporate Literature Center U.S. FAX: (602) 786-7277
4. The Microchip's Bulletin Board, via your local CompuServe number (CompuServe membership NOT required).

Please specify which device, revision of silicon and Data Sheet (include Literature #) you are using.

For latest version information and upgrade kits for Microchip Development Tools, please call 1-800-755-2345 or 1-602-786-7302.
