

# Quad, 12-14-16 Bit *nanoDAC*™ with 5ppm/°C On-Chip Reference in MSOP

Preliminary Technical Data

AD5624R/AD5644R/AD5664R

## FEATURES

Low Power Smallest Pin compatible Quad *nanoDAC*s

AD5664R: 16 Bits

AD5644R: 14 Bits

AD5624R: 12 Bits

On-chip 1.25/2.5V, 5ppm/°C Reference

10-lead MSOP and 3mmx3mm LFCSP package

Power-down to 480 nA @ 5 V, 100 nA @ 3 V

3 V / 5 V power supply

Guaranteed 16-bit monotonic by design

3 power-down functions

Serial interface with Schmitt-triggered inputs

Rail-to-rail operation

SYNC interrupt facility

## APPLICATIONS

Process control

Data acquisition systems

Portable battery-powered instruments

Digital gain and offset adjustment

Programmable voltage and current sources

Programmable attenuators

## GENERAL DESCRIPTION

The AD5624R/AD5644R/AD5664R, members of the *nanoDAC* family, are low power, quad, 16-bit buffered voltage-out DAC that operates from a single 2.7 V to 5.5 V supply and is guaranteed monotonic by design.

The AD5624R/AD5644R/AD5664R have an on-chip reference with an internal gain of two. The AD56x4-3 has a 1.25V 5ppm/°C max reference and the AD56x4-5 have a 2.5V 5ppm/°C reference. The on-board reference is off at power-up allowing the use of an external reference. The internal reference is turned on by writing to the DAC.

The part incorporates a power-on reset circuit that ensures the DAC output powers up to 0 V and remains there until a valid write takes place. The part contains a power-down feature that reduces the current consumption of the device to 480 nA at 5 V and provides software-selectable output loads while in power-down mode. The low power consumption of this part in normal operation makes it ideally suited to portable battery-operated equipment.

## FUNCTIONAL BLOCK DIAGRAM

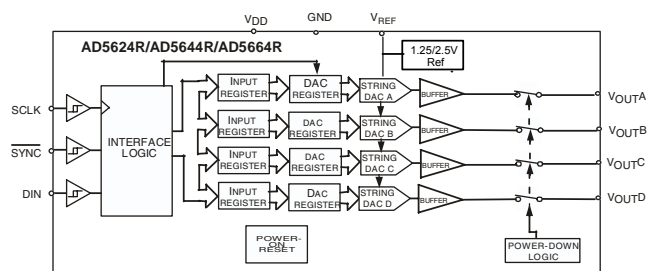

Figure 1.

## RELATED DEVICES

Part No.	Description
AD5664	2.7V to 5.5V 16-bit DAC, external reference
AD5666	

The AD5624R/AD5644R/AD5664R's on-chip precision output amplifier allows rail-to-rail output swing to be achieved.

The AD5624R/AD5644R/AD5664R uses a versatile 3-wire serial interface that operates at clock rates up to 50 MHz, and is compatible with standard SPI®, QSPI™, MICROWIRE™, and DSP interface standards.

## PRODUCT HIGHLIGHTS

1. Quad 12-14-16-bit DAC
2. On-chip 1.25/2.5V, 5ppm/°C Reference
3. Available in 10-lead MSOP and 10-lead 3mmx3mm LFCSP package.
4. Low power. Typically consumes 0.42 mW at 3 V and 0.75 mW at 5 V.  
10 μs max settling time.

## NOTES

<sup>1</sup>Guaranteed by design and characterization; not production tested.<sup>2</sup>See the Terminology section.

## TIMING CHARACTERISTICS

All input signals are specified with  $t_r = t_f = 1 \text{ ns/V}$  (10% to 90% of  $V_{DD}$ ) and timed from a voltage level of  $(V_{IL} + V_{IH})/2$ . See Figure 2.  $V_{DD} = 2.7 \text{ V}$  to  $5.5 \text{ V}$ ; all specifications  $T_{MIN}$  to  $T_{MAX}$ , unless otherwise noted.

**Table 3.**

Parameter	Limit at $T_{MIN}, T_{MAX}$	Unit	Conditions/Comments
	$V_{DD} = 2.7 \text{ V to } 5.5 \text{ V}$		
$t_1^1$	20	ns min	SCLK cycle time
$t_2$	9	ns min	SCLK high time
$t_3$	9	ns min	SCLK low time
$t_4$	13	ns min	$\overline{\text{SYNC}}$ to SCLK falling edge setup time
$t_5$	4	ns min	Data setup time
$t_6$	4	ns min	Data hold time
$t_7$	0	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ rising edge
$T_8$	50	ns min	Minimum $\overline{\text{SYNC}}$ high time
$t_9$	13	ns min	$\overline{\text{SYNC}}$ rising edge to sclk fall ignore
$t_{10}$	0	ns min	SCLK falling edge to $\overline{\text{SYNC}}$ fall ignore

<sup>1</sup> Maximum SCLK frequency is 50 MHz at  $V_{DD} = 3.6 \text{ V}$  to  $5.5 \text{ V}$ , and tbd MHz at  $V_{DD} = 2.7 \text{ V}$  to  $3.6 \text{ V}$ .

Figure 2. Serial Write Operation

## ABSOLUTE MAXIMUM RATINGS

$T_A = 25^\circ\text{C}$ , unless otherwise noted.

Table 4.

Parameter	Rating
$V_{DD}$ to GND	$-0.3\text{ V to }+7\text{ V}$
$V_{OUT}$ to GND	$-0.3\text{ V to }V_{DD} + 0.3\text{ V}$
$V_{REF}$ to GND	$-0.3\text{ V to }V_{DD} + 0.3\text{ V}$
Digital Input Voltage to GND	$-0.3\text{ V to }V_{DD} + 0.3\text{ V}$
Operating Temperature Range	
Industrial (A, B Version)	$-40^\circ\text{C to }+105^\circ\text{C}$
Storage Temperature Range	$-65^\circ\text{C to }+150^\circ\text{C}$
Junction Temperature ( $T_J$ max)	$150^\circ\text{C}$
Power Dissipation	$(T_J \text{ max} - T_A)/\theta_{JA}$
LFCSP Package (4-Layer Board)	
$\theta_{JA}$ Thermal Impedance	$61^\circ\text{C/W}$
MSOP Package (4-Layer Board)	
$\theta_{JA}$ Thermal Impedance	$142^\circ\text{C/W}$
$\theta_{JC}$ Thermal Impedance	$43.7^\circ\text{C/W}$
Reflow Soldering Peak Temperature	
Pb-free	$260^\circ\text{C} \pm 5^\circ\text{C}$

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those listed in the operational sections of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTION

Figure 3. MSOP and LFCSP Pin Configuration

Table 5. Pin Function Descriptions

Pin No.	Mnemonic	Function
1	V <sub>OUTA</sub>	Analog Output Voltage from DAC A. The output amplifier has rail-to-rail operation.
2	V <sub>OUTB</sub>	Analog Output Voltage from DAC B. The output amplifier has rail-to-rail operation.
3	GND	Ground Reference Point for All Circuitry on the Part.
4	V <sub>OUTC</sub>	Analog Output Voltage from DAC C. The output amplifier has rail-to-rail operation.
5	V <sub>OUTD</sub>	Analog Output Voltage from DAC D. The output amplifier has rail-to-rail operation.
6	SYNC	Level-Triggered Control Input (Active Low). This is the frame synchronization signal for the input data. When SYNC goes low, it enables the input shift register, and data is transferred in on the falling edges of the following clocks. The DAC is updated following the 24 <sup>th</sup> clock cycle unless SYNC is taken high before this edge, in which case the rising edge of SYNC acts as an interrupt and the write sequence is ignored by the DAC.
7	SCLK	Serial Clock Input. Data is clocked into the input shift register on the falling edge of the serial clock input. Data can be transferred at rates up to 50 MHz.
8	DIN	Serial Data Input. This device has a 24-bit shift register. Data is clocked into the register on the falling edge of the serial clock input.
9	V <sub>DD</sub>	Power Supply Input. These parts can be operated from 2.7 V to 5.5 V. V <sub>DD</sub> should be decoupled to GND.
10	V <sub>REFIN</sub> /V <sub>REFOUT</sub>	The AD56x4R has a common reference input/reference output Pin. When the internal reference is selected this is the reference output pin. When using an external reference, this is the reference input pin. The default for this pin is a reference input.

## TERMINOLOGY

### Relative Accuracy or Integral Nonlinearity (INL)

For the DAC, relative accuracy or integral nonlinearity is a measurement of the maximum deviation, in LSBs, from a straight line passing through the endpoints of the DAC transfer function. A typical INL vs. code plot can be seen in Figure 4.

### Differential Nonlinearity (DNL)

Differential nonlinearity is the difference between the measured change and the ideal 1 LSB change between any two adjacent codes. A specified differential nonlinearity of  $\pm 1$  LSB maximum ensures monotonicity. This DAC is guaranteed monotonic by design. A typical DNL vs. code plot can be seen in Figure 5.

### Zero-Code Error

Zero-code error is a measurement of the output error when zero code (0x0000) is loaded to the DAC register. Ideally, the output should be 0 V. The zero-code error is always positive in the AD5664 because the output of the DAC cannot go below 0 V. It is due to a combination of the offset errors in the DAC and the output amplifier. Zero-code error is expressed in mV. A plot of zero-code error vs. temperature can be seen in Figure 11.

### Full-Scale Error

Full-scale error is a measurement of the output error when full-scale code (0xFFFF) is loaded to the DAC register. Ideally, the output should be  $V_{DD} - 1$  LSB. Full-scale error is expressed in percent of full-scale range. A plot of full-scale error vs. temperature can be seen in Figure 10.

### Gain Error

This is a measure of the span error of the DAC. It is the deviation in slope of the DAC transfer characteristic from ideal expressed as a percent of the full-scale range.

### Total Unadjusted Error (TUE)

Total unadjusted error is a measurement of the output error, taking all the various errors into account. A typical TUE vs. code plot can be seen in Figure 6.

### Zero-Code Error Drift

This is a measurement of the change in zero-code error with a change in temperature. It is expressed in  $\mu\text{V}/^\circ\text{C}$ .

### Gain Temperature Coefficient

This is a measurement of the change in gain error with changes in temperature. It is expressed in (ppm of full-scale range)/ $^\circ\text{C}$ .

### Offset Error

Offset error is a measure of the difference between  $V_{\text{OUT}}$  (actual) and  $V_{\text{OUT}}$  (ideal) expressed in mV in the linear region of the transfer function. Offset error is measured on the AD5664 with code 512 loaded in the DAC register. It can be negative or positive.

### DC Power Supply Rejection Ratio (PSRR)

This indicates how the output of the DAC is affected by changes in the supply voltage. PSRR is the ratio of the change in  $V_{\text{OUT}}$  to a change in  $V_{\text{DD}}$  for full-scale output of the DAC. It is measured in dB.  $V_{\text{REF}}$  is held at 2 V, and  $V_{\text{DD}}$  is varied by  $\pm 10\%$ .

### Output Voltage Settling Time

This is the amount of time it takes for the output of a DAC to settle to a specified level for a  $\frac{1}{4}$  to  $\frac{3}{4}$  full-scale input change and is measured from the 24<sup>th</sup> falling edge of SCLK.

### Digital-to-Analog Glitch Impulse

Digital-to-analog glitch impulse is the impulse injected into the analog output when the input code in the DAC register changes state. It is normally specified as the area of the glitch in nV-s, and is measured when the digital input code is changed by 1 LSB at the major carry transition (0x7FFF to 0x10000). See Figure 25 and Figure 26.

### Digital Feedthrough

Digital feedthrough is a measure of the impulse injected into the analog output of the DAC from the digital inputs of the DAC, but is measured when the DAC output is not updated. It is specified in nV-s, and measured with a full-scale code change on the data bus, that is, from all 0s to all 1s and vice versa.

### Total Harmonic Distortion (THD)

This is the difference between an ideal sine wave and its attenuated version using the DAC. The sine wave is used as the reference for the DAC, and the THD is a measurement of the harmonics present on the DAC output. It is measured in dB.

### Noise Spectral Density

This is a measurement of the internally generated random noise. Random noise is characterized as a spectral density (voltage per  $\sqrt{\text{Hz}}$ ). It is measured by loading the DAC to midscale and measuring noise at the output. It is measured in  $\text{nV}/\sqrt{\text{Hz}}$ . A plot of Noise Spectral Density can be seen in Figure 31.

### DC Crosstalk

This is the dc change in the output level of one DAC in response to a change in the output of another DAC. It is measured with a full-scale output change on one DAC while monitoring another DAC kept at midscale. It is expressed in  $\mu\text{V}$ .

### Channel-to-Channel Isolation

This is the ratio of the amplitude of the signal at the output of one DAC to a sine wave on the reference input of another DAC. It is measured in dB.

### Digital Crosstalk

This is the glitch impulse transferred to the output of one DAC at midscale in response to a full-scale code change (all 0s to all 1s and

vice versa) in the input register of another DAC. It is measured in standalone mode and is expressed in nV-s.

**Analog Crosstalk**

This is the glitch impulse transferred to the output of one DAC due to a change in the output of another DAC. It is measured by loading one of the input registers with a full-scale code change (all 0s to all 1s and vice versa) while keeping *LDAC* high. Then pulse *LDAC* low and monitor the output of the DAC whose digital code was not changed. The area of the glitch is expressed in nV-s.

**DAC-to-DAC Crosstalk**

This is the glitch impulse transferred to the output of one DAC due to a digital code change and subsequent output change of another

DAC. This includes both digital and analog crosstalk. It is measured by loading one of the DACs with a full-scale code change (all 0s to all 1s and vice versa) with *LDAC* low and monitoring the output of another DAC. The energy of the glitch is expressed in nV-s.

**Multiplying Bandwidth**

The amplifiers within the DAC have a finite bandwidth. The multiplying bandwidth is a measure of this. A sine wave on the reference (with full-scale code loaded to the DAC) appears on the output. The multiplying bandwidth is the frequency at which the output amplitude falls to 3 dB below the input.

## THEORY OF OPERATION

### D/A SECTION

The AD5624R/AD5644R/AD5664R DAC's are fabricated on a CMOS process. The architecture consists of a string DAC followed by an output buffer amplifier. Figure 32 shows a block diagram of the DAC architecture.

Figure 32. DAC Architecture

Since the input coding to the DAC is straight binary, the ideal output voltage is given by:

$$V_{OUT} = V_{refin} \times \left( \frac{D}{2^N} \right)$$

when using an external reference;

$$V_{OUT} = 2 * V_{refout} \times \left( \frac{D}{2^N} \right)$$

when using the internal reference;

where  $D$  = decimal equivalent of the binary code that is loaded to the DAC register;

0 - 4095 for AD5624R (12 bit)

0 - 16383 for AD5644R (14 bit)

0 - 65535 for AD5664R (16 bit)

$N$  = the DAC resolution

### RESISTOR STRING

The resistor string section is shown in Figure 33. It is simply a string of resistors, each of value  $R$ . The code loaded to the DAC register determines at which node on the string the voltage is tapped off to be fed into the output amplifier. The voltage is tapped off by closing one of the switches connecting the string to the amplifier. Because it is a string of resistors, it is guaranteed monotonic.

Figure 33. Resistor String

### OUTPUT AMPLIFIER

The output buffer amplifier can generate rail-to-rail voltages on its output, which gives an output range of 0 V to  $V_{DD}$ . It can drive a load of 2 k $\Omega$  in parallel with 1000 pF to GND. The source and sink capabilities of the output amplifier can be seen in Figure 15. The slew rate is 1.5 V/ $\mu$ s with a 1/4 to 3/4 full-scale settling time of 10  $\mu$ s.

### INTERNAL REFERENCE

The AD5624R/AD5644R/AD5664R has an on-chip reference with an internal gain of two. The AD56x4R-3 has a 1.25V 10ppm/ $^{\circ}$ C max reference giving a fullscale output of 2.5V and the AD56x4R-5 has a 2.5V 10ppm/ $^{\circ}$ C max reference giving a fullscale output of 5V. The on-board reference is off at power-up allowing the use of an external reference. The internal reference is enabled via a write to a control register

The internal reference associated with each part is available at the  $V_{REFOUT}$  pin. A buffer is required if the reference output is used to drive external loads

When using the internal reference, it is recommended that a 100nF capacitor is placed between reference output and GND for reference stability.

### SERIAL INTERFACE

The AD5624R/AD5644R/AD5664R has a 3-wire serial interface (SYNC, SCLK, and DIN) that is compatible with SPI, QSPI, and MICROWIRE interface standards as well as with most DSPs. See Figure 2 for a timing diagram of a typical write sequence.

The write sequence begins by bringing the  $\overline{\text{SYNC}}$  line low. Data from the DIN line is clocked into the 24-bit shift register on the falling edge of SCLK. The serial clock frequency can be as high

as 50 MHz, making the AD5624R/AD5644R/AD5664R compatible with high speed DSPs. On the 24<sup>th</sup> falling clock edge, the last data bit is clocked in and the programmed function is executed, that is, a change in DAC register contents and/or a change in the mode of operation. At this stage, the  $\overline{\text{SYNC}}$  line can be kept low or be brought high. In either case, it must be brought high for a minimum of 33 ns before the next write sequence so that a falling edge of  $\overline{\text{SYNC}}$  can initiate the next write sequence. Since the  $\overline{\text{SYNC}}$  buffer draws more current when  $V_{\text{IN}} = 2 \text{ V}$  than it does when  $V_{\text{IN}} = 0.8 \text{ V}$ ,  $\overline{\text{SYNC}}$  should be idled low between write sequences for even lower power operation. As mentioned previously it must, however, be brought high again just before the next write sequence.

### INPUT SHIFT REGISTER

The input shift register is 24 bits wide (see figure 34). The first two bits are don't cares. The next three are the Command bits C2 – C0, (see Table 1) followed by the 3-bit DAC address A2–A0, (see Table 2) and finally the 16-14-12-bit data word. The data word comprises the 16- 14- 12- bit input code followed by 0, 2 or 4 don't care bits, the AD5664R, AD5644R and AD5624R respectively. See figure 34, 35, 36. These data bits are transferred to the DAC register on the 24<sup>th</sup> falling edge of SCLK.

### $\overline{\text{SYNC}}$ INTERRUPT

In a normal write sequence, the  $\overline{\text{SYNC}}$  line is kept low for at least 24 falling edges of SCLK, and the DAC is updated on the 24<sup>th</sup> falling edge. However, if  $\overline{\text{SYNC}}$  is brought high before the 24<sup>th</sup> falling edge, this acts as an interrupt to the write sequence. The shift register is reset and the write sequence is seen as invalid. Neither an update of the DAC register contents nor a change in the operating mode occurs (see figure 37).

### POWER-ON RESET

The AD5624R/AD5644R/AD5664R family contains a power-on reset circuit that controls the output voltage during power-up. The AD5624R/AD5644R/AD5664R DAC outputs power up to 0 V and the output remains there until a valid write sequence is made to the DAC. This is useful in applications where it is important to know the state of the output of the DAC while it is in the process of powering up.

### SOFTWARE RESET

The AD5624R/AD5644R/AD5664R contains a Software Reset function. Command 101 is reserved for the Software Reset function, see Table 1. The Software Reset command contains two reset modes that are software-programmable by setting bit DB0 in the control register. Table 5 shows how the state of the bit corresponds to the mode of operation of the device.

Table 6. Software Reset Modes for the AD5664

## POWER-DOWN MODES

The AD5624R/AD5644R/AD5664R contains four separate modes of operation. Command 100 is reserved for the Power-Down function. See Table 1. These modes are software-programmable by setting two bits (DB5 and DB4) in the control register. Table 6 shows how the state of the bits corresponds to the mode of operation of the device. Any or all DACs, (DacD to DacA) may be powered down to the selected mode by setting the corresponding 4 bits (DB3, DB2, DB1, DB 0) to a “1”. By executing the same Command 100, any combination of DACs may be powered up by setting the bits (DB5 and DB4) to Normal Operation mode. Again, to select which combination of DAC channels to power-up set the corresponding 4 bits (DB3, DB2, DB1, DB 0) to a “1”. See Table 7 for contents of the Input Shift Register during power down/up operation.

The DAC output will power-up to the value in the input register while /LDAC is low. If /LDAC is high, the DAC output will power-up to the value held in the DAC register before power-down.

**Table 7. Modes of Operation for the AD5624R/AD5644R/AD5664R**

**Table 7. 24-Bit Input Shift Register Contents of Power Up/Down Function for the AD5624R/AD5644R/AD5664R**

When both bits are set to 0, the part works normally with its normal power consumption of 500  $\mu$ A at 5 V. However, for the three power-down modes, the supply current falls to 480 nA at 5 V (100 nA at 3 V). Not only does the supply current fall, but the output stage is also internally switched from the output of the amplifier to a resistor network of known values. This has the advantage that the output impedance of the part is known while the part is in power-down mode. The outputs can either be connected internally to GND through a 1 kΩ or 100 kΩ resistor, or left open-circuited (three-state) (see figure 35).

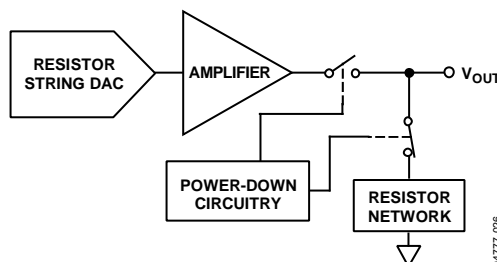

Figure 35. Output Stage During Power-Down

The bias generator, the output amplifier, the resistor string, and other associated linear circuitry are shut down when power-down mode is activated. However, the contents of the DAC register are unaffected when in power-down. The time to exit power-down is typically 4  $\mu$ s for  $V_{DD} = 5$  V and for  $V_{DD} = 3$  V (see Figure 24).

**LDAC FUNCTION**

The AD5624R/AD5644R/AD5664R do not have a hardware /LDAC pin. Writing to the DAC using command 110, allows one to perform a software /LDAC on any or all of the DAC channels. The DAC channels are selected by setting the bits of the 4-bit /LDAC register (DB3, DB2, DB1, DB0). See Table 8 for the software /LDAC mode of operation. Setting the /LDAC bit to a “1” means the DAC registers are automatically updated after new data is read in on the falling edge of the 24th SCLK pulse. This is equivalent to having an /LDAC hardware pin tied permanently low for the selected DAC channel. See Table 9 for contents of the Input Shift Register during the /LDAC overwrite mode of operation.

Load DAC Register	
/LDACBITS (DB3-DB0)	/LDAC Operation
0	Normal operation - default
1	The DAC registers are updated after new data is read in on the falling edge of the 24 <sup>th</sup> SCLK pulse.

**INTERNAL REFERENCE SETUP**

The on-board reference is off at power-up by default. This allows the use of an external reference if the application requires it. The AD5624R/AD5644R/AD5664R-3 have a 1.25V 10ppm/°C max reference giving a fullscale output of 2.5V and the AD5624R/AD5644R/AD5664R-5 have a 2.5V 10ppm/°C max reference giving a fullscale output of 5V. The on-board reference can be turned on/off by a user programmable REF Setup register by setting the bit DB0 high or low, see Table 3. Command 111 is reserved for this Internal REF Setup command, see Table 1. **Error! Reference source not found.**4 shows how the state of the bits in the Input Shift Register corresponds to the mode of operation of the device.

## MICROPROCESSOR INTERFACING

### AD5624R/AD5644R/AD5664R to Blackfin® ADSP-BF53X Interface

Figure 36 shows a serial interface between the AD5624R/AD5644R/AD5664R and the Blackfin ADSP-BF53X microprocessor. The ADSP-BF53X processor family incorporates two dual-channel synchronous serial ports, SPORT1 and SPORT0, for serial and multiprocessor communications. Using SPORT0 to connect to the AD5624R/AD5644R/AD5664R, the setup for the interface is as follows. DT0PRI drives the DIN pin of the AD5624R/AD5644R/AD5664R, while TSCLK0 drives the SCLK of the part. The SYNC is driven from TFS0.

\*ADDITIONAL PINS OMITTED FOR CLARITY

Figure 36. AD5624R/AD5644R/AD5664R to Blackfin ADSP-BF53X Interface

### AD5624R/AD5644R/AD5664R to 68HC11/68L11 Interface

Figure 37 shows a serial interface between the AD5624R/AD5644R/AD5664R and the 68HC11/68L11 microcontroller. SCK of the 68HC11/68L11 drives the SCLK of the AD5624R/AD5644R/AD5664R, while the MOSI output drives the serial data line of the DAC.

The SYNC signal is derived from a port line (PC7). The setup conditions for correct operation of this interface are as follows. The 68HC11/68L11 is configured with its CPOL bit as a 0 and its CPHA bit as a 1. When data is being transmitted to the DAC, the SYNC line is taken low (PC7). When the 68HC11/68L11 is configured as described above, data appearing on the MOSI

output is valid on the falling edge of SCK. Serial data from the 68HC11/68L11 is transmitted in 8-bit bytes with only eight falling clock edges occurring in the transmit cycle. Data is transmitted MSB first. In order to load data to the AD5624R/AD5644R/AD5664R, PC7 is left low after the first eight bits are transferred, and a second serial write operation is performed to the DAC; PC7 is taken high at the end of this procedure.

\*ADDITIONAL PINS OMITTED FOR CLARITY

Figure 37. AD5624R/AD5644R/AD5664R to 68HC11/68L11 Interface

**AD5624R/AD5644R/AD5664R to 80C51/80L51 Interface**

Figure 38 shows a serial interface between the AD5624R/AD5644R/AD5664R and the 80C51/80L51 microcontroller. The setup for the interface is as follows. TXD of the 80C51/80L51 drives SCLK of the AD5624R/AD5644R/AD5664R, while RXD drives the serial data line of the part. The SYNC signal is again derived from a bit-programmable pin on the port. In this case, port line P3.3 is used. When data is to be transmitted to the AD5624R/AD5644R/AD5664R, P3.3 is taken low. The 80C51/80L51 transmits data in 8-bit bytes only; thus only eight falling clock edges occur in the transmit cycle. To load data to the DAC, P3.3 is left low after the first eight bits are transmitted, and a second write cycle is initiated to transmit the second byte of data. P3.3 is taken high following the completion of this cycle. The 80C51/80L51 outputs the serial data in a format that has the LSB first. The AD5624R/AD5644R/AD5664R must receive data with the MSB first. The 80C51/80L51 transmit routine should take this into account.

\*ADDITIONAL PINS OMITTED FOR CLARITY

Figure 38. AD5624R/AD5644R/AD5664R to 80C51/80L51 Interface

**AD5624R/AD5644R/AD5664R to MICROWIRE Interface**

Figure 39 shows an interface between the AD5624R/AD5644R/AD5664R and any MICROWIRE-compatible device. Serial data is shifted out on the falling edge of the serial clock and is clocked into the AD5624R/AD5644R/AD5664R on the rising edge of the SK.

\*ADDITIONAL PINS OMITTED FOR CLARITY

Figure 39. AD5624R/AD5644R/AD5664R to MICROWIRE Interface

## APPLICATIONS

### USING A REFERENCE AS A POWER SUPPLY FOR THE AD5624R/AD5644R/AD5664R

Because the supply current required by the AD5624R/AD5644R/AD5664R is extremely low, an alternative option is to use a voltage reference to supply the required voltage to the part (see Figure 40). This is especially useful if the power supply is quite noisy, or if the system supply voltages are at some value other than 5 V or 3 V, for example, 15 V. The voltage reference outputs a steady supply voltage for the AD5624R/AD5644R/AD5664R; see Error! Reference source not found. for a suitable reference. If the low dropout REF195 is used, it must supply 500  $\mu$ A of current to the AD5624R/AD5644R/AD5664R, with no load on the output of the DAC. When the DAC output is loaded, the REF195 also needs to supply the current to the load. The total current required (with a 5 k $\Omega$  load on the DAC output) is

$$500 \mu\text{A} + (5 \text{ V} / 5 \text{ k}\Omega) = 1.25 \text{ mA}$$

The load regulation of the REF195 is typically 2 ppm/mA, which results in a 3 ppm (15  $\mu$ V) error for the 1.5 mA current drawn from it. This corresponds to a 0.196 LSB error.

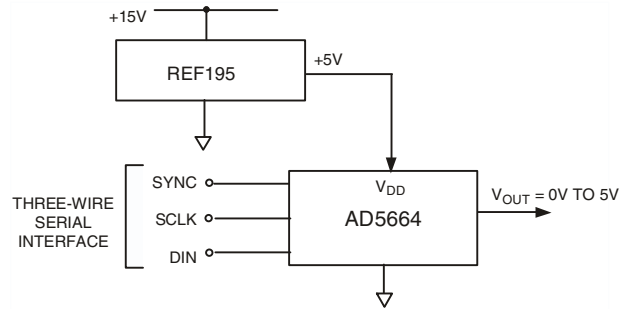

Figure 40. REF195 as Power Supply to the AD5624R/AD5644R/AD5664

## BIPOLAR OPERATION USING THE AD5624R/AD5644R/AD5664R

The AD5624R/AD5644R/AD5664R has been designed for single-supply operation, but a bipolar output range is also possible using the circuit in Figure 41. The circuit gives an output voltage range of  $\pm 5$  V. Rail-to-rail operation at the amplifier output is achievable using an AD820 or an OP295 as the output amplifier.

The output voltage for any input code can be calculated as follows:

$$V_O = \left[ V_{DD} \times \left( \frac{D}{65,536} \right) \times \left( \frac{R1 + R2}{R1} \right) - V_{DD} \times \left( \frac{R2}{R1} \right) \right]$$

where  $D$  represents the input code in decimal (0 to 65535).

With  $V_{DD} = 5$  V,  $R1 = R2 = 10$  k $\Omega$ ,

$$V_O = \left( \frac{10 \times D}{65,536} \right) - 5$$

This is an output voltage range of  $\pm 5$  V, with 0x0000 corresponding to a  $-5$  V output, and 0xFFFF corresponding to a  $+5$  V output.

Figure 41. Bipolar Operation with the AD5624R/AD5644R/AD5664R

## USING AD5624R/AD5644R/AD5664R WITH A GALVANICALLY ISOLATED INTERFACE

In process-control applications in industrial environments, it is often necessary to use a galvanically isolated interface to protect and isolate the controlling circuitry from any hazardous common-mode voltages that might occur in the area where the DAC is functioning. Isocouplers provide isolation in excess of 3 kV. The AD5624R/AD5644R/AD5664R uses a 3-wire serial logic interface, so the ADuM130x 3-channel digital isolator provides the required isolation (see Figure 42). The power supply to the part also needs to be isolated, which is done by using a transformer. On the DAC side of the transformer, a 5 V regulator provides the 5 V supply required for the AD5624R/AD5644R/AD5664R.

Figure 42. AD5624R/AD5644R/AD5664R with a Galvanically Isolated Interface

**POWER SUPPLY BYPASSING AND GROUNDING**

When accuracy is important in a circuit, it is helpful to carefully consider the power supply and ground return layout on the board. The printed circuit board containing the AD5624R/AD5644R/AD5664R should have separate analog and digital sections, each having its own area of the board. If the AD5624R/AD5644R/AD5664R is in a system where other devices require an AGND-to-DGND connection, the connection should be made at one point only. This ground point should be as close as possible to the AD5624R/AD5644R/AD5664R.

The power supply to the AD5624R/AD5644R/AD5664R should be bypassed with 10  $\mu\text{F}$  and 0.1  $\mu\text{F}$  capacitors. The capacitors should be located as close as possible to the device, with the 0.1  $\mu\text{F}$  capacitor ideally right up against the device. The 10  $\mu\text{F}$  capacitors are the tantalum bead type. It is important that the 0.1  $\mu\text{F}$  capacitor has low effective series resistance (ESR) and effective series inductance (ESI), for example, common ceramic

types of capacitors. This 0.1  $\mu\text{F}$  capacitor provides a low impedance path to ground for high frequencies caused by transient currents due to internal logic switching.

The power supply line itself should have as large a trace as possible to provide a low impedance path and to reduce glitch effects on the supply line. Clocks and other fast switching digital signals should be shielded from other parts of the board by digital ground. Avoid crossover of digital and analog signals if possible. When traces cross on opposite sides of the board, ensure that they run at right angles to each other to reduce feedthrough effects through the board. The best board layout technique is the microstrip technique where the component side of the board is dedicated to the ground plane only and the signal traces are placed on the solder side. However, this is not always possible with a 2-layer board.

## OUTLINE DIMENSIONS
