

# QL903M QuickMIPS™ Data Sheet

## QuickMIPS Embedded Standard Product (ESP) Family

### Device Highlights

#### CPU Core

- 32-bit MIPS 4Kc processor runs up to 200 MHz (260 Dhrystone MIPS)
- 1.3 Dhrystone MIPS per MHz
- MDU supports MAC instructions for DSP functions
- 16 KB of instruction cache (4-way set associative)
- 16 KB of data cache (4-way set associative), lockable on a per line basis

#### SDRAM Memory Controller

- Support for PC-100 type SDRAMs, up to 256 MB total
- Two chip selects
- Operates at up to one-half CPU pipeline speed
- Support for x16 and x32 external memory bus configurations

#### I/O Peripheral Controller

- Direct support for SRAM, EPROM and Flash
- 8-bit, 16-bit and 32-bit device widths supported
- Eight independent chip selects

#### PCI Controller

- 32-bit v2.2 compatible
- Up to 66 MHz operation
- Supports host and satellite configurations
- Dedicated DMA channels for transmit and receive bus transactions
- Support for external bus master arbitration (through FPGA library provided by QuickLogic)

### Two Ethernet Controllers

- Two 10/100 MACs
- Provides MII connection to external transceivers/devices

### Two UARTs

- One with modem control signals
- Both with IRDA-compliant signals

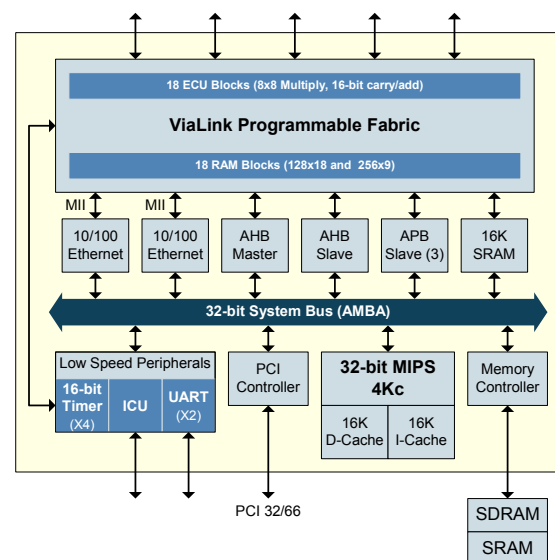

### Four General Purpose 16-bit Timer/Counters

- 16-bit prescaler to increase timer/counter delay
- Four modes of operation: decrement, increment, interval, and Pulse Width Modulation (PWM)
- Operation from the System Bus clock or a clock source supplied from the Programmable Fabric

### System SRAM

- 16 KB accessible by all System Bus masters or the Programmable Fabric

Figure 1: QL903M Block Diagram

## High Performance 32-bit System Bus (AMBA Bus)

- Operates at one-half, one-third, or one-fourth of CPU pipeline speed
- One 32-bit AHB master port/one 32-bit AHB slave port to programmable Fabric
- Three 32-bit APB slave ports in the programmable Fabric

## Flexible Programmable Fabric

- 1152 logic cells (316 K system gates)
- 124 I/O pins
- 1.95 V Vcc, 1.8/2.5/3.3 V drive capable I/O
- 2,510 dedicated flip-flops
- IEEE 1149.1 boundary scan testing compliant

## Dual-Port SRAM Modules

- Eighteen 2,304 bit Dual-Port High Performance SRAM Blocks
- 41,472 embedded RAM bits
- RAM/ROM/FIFO Wizard for automatic configuration
- Configurable and cascadable

## Programmable I/O

- High performance I/O cell with fast clock-to-out time
- Programmable Slew Rate Control
- Programmable I/O Standards:
  - LVTTTL, LVCMOS, LVCMOS18, PCI, GTL+, SSTL2, and SSTL3
  - Independent I/O Banks capable of supporting multiple standards in one device
  - I/O Register Configurations: Input, Output, Output Enable (OE)

## Advanced Clock Network

- Multiple dedicated Low Skew Clock Networks
- High drive input-only networks
- Quadrant-based segmentable clock networks
- User-programmable Phase Locked Loop (PLL) circuit

## Embedded Computational Units (ECUs)

Eighteen hardwired DSP building blocks with integrated Multiply, Add, and Accumulate functions.

## Security Features

The QuickLogic products come with secure ViaLink® technology that protects intellectual property from design theft and reverse engineering. No external configuration memory is needed for the Fabric. The device is instant-on at power-up.

## QuickWorks Design Software

The QuickWorks® package provides the most complete ESP and Field Programmable Gate Array (FPGA) software solution from design entry to logic synthesis, to place and route, and simulation. The package provides a solution for designers who use third party tools from Cadence, Mentor, Synopsys, and other third-party tools for design entry, synthesis, or simulation.

## Process Data

The QL903M is fabricated on a 0.18  $\mu$ m, six layer metal CMOS process. The core voltage is 1.95 V  $V_{CC}$  supply and the I/Os are up to 3.3 V compliant. The QL903M is available in commercial and industrial temperature grades.

## QL903M Architectural Overview

The QL903M chip can be thought of as having two distinct *sides*, an Application Specific Standard Product (ASSP) side and a Programmable Fabric side. The ASSP side contains the standard cell circuitry of the device such as the MIPS 4Kc CPU and the Ethernet MACs, and the Fabric side contains all of the programmable logic elements (e.g., logic cells and dual-port RAMs) of the device.

### ASSP Side

This section discusses the various circuits in the ASSP portion of the QL903M device.

#### CPU Core

The MIPS32 4Kc processor core is a high-performance, low-power, 32-bit MIPS RISC core capable of speeds up to 200 MHz. The 4Kc core contains a fully-associative translation lookaside buffer (TLB) based Memory Management Unit (MMU) and a pipelined MDU.

The core executes the MIPS32 instruction set architecture (ISA). It supports all application code in the MIPS I, II, III, and IV instruction sets. It also supports kernel code for the R4000 processor and above. The MIPS32 ISA contains special multiply-accumulate, conditional move, prefetch, wait, and zero/one detect instructions. The MMU contains a three-entry instruction TLB (ITLB), a three-entry data TLB (DTLB), and a 16 dual-entry joint TLB (JTLB) with variable page sizes.

The 4Kc multiply-divide unit (MDU) supports a maximum issue rate of one 32x16 multiply (MUL/MULT/MULTU), multiply-add (MADD/MADDU), or multiply-subtract (MSUB/MSUBU) operation per clock, or one 32x32 MUL, MADD, or MSUB every other clock.

#### Instruction and Data Caches

The instruction and data caches are both 16 Kbytes in size. Each cache is organized as four-way set associative. The data cache has lockout capability per cache line. On a cache miss, loads are blocked only until the first critical word becomes available. The pipeline resumes execution while the remaining words are being written to the cache. Both caches are virtually indexed and physically tagged. Virtual indexing allows the cache to be indexed in the same clock in which the address is generated rather than waiting for the virtual-to physical address translation in the MMU.

#### EJTAG Interface

The basic Enhanced JTAG (EJTAG) features provide CPU run control with stop, single stepping and re-start, and software breakpoints through the SDBBP instruction. In addition, instruction and data virtual address hardware breakpoints, and connection to an external EJTAG probe through the Test Access Port (TAP) is included.

## ASSP PLL

On the ASSP side of the QL903M there is a single clock input that provides an input clock reference for the MIPS core, the System Bus, and all ASSP peripherals (other than the PCI Controller, which is independently driven by the PCI\_CLK input). This clock input (CPU\_PLL\_CLKIN) is the input to a PLL that is fixed at an 8 times clock multiplication rate. For example, if the clock rate applied to CPU\_PLL\_CLKIN is 25 MHz, the resultant clock that drives the MIPS core is 200 MHz. **Table 1** shows the maximum input clock rates for CPU\_PLL\_CLKIN based upon the ASSP speed grade of the given QL903M device.

**Table 1: Maximum Input Frequency for CPU\_PLL\_CLKIN and MIPS Core Frequency Based on QL903M ASSP Speed Grade**

| QuickMIPS Device Part Number Prefix | Maximum Input Frequency for CPU_PLL_CLKIN | Resultant Maximum MIPS Core Frequency |
|-------------------------------------|-------------------------------------------|---------------------------------------|
| QL903M175                           | 21.875 MHz                                | 175 MHz                               |
| QL903M200                           | 25.000 MHz                                | 200 MHz                               |

The System Bus clock can run at a maximum rate of one-half the MIPS core clock frequency. Other ratios (one-third and one-fourth) are also possible and controlled by the CPU\_PLL\_DIV(1) and CPU\_PLL\_DIV(0) inputs as shown in **Table 2**.

**Table 2: MIPS Core Clock Rate to System Bus Clock Rate (hclk) Ratio Based on CPU\_PLL\_DIV(1) and CPU\_PLL\_DIV(0) Signals**

| CPU_PLL_DIV(1) | CPU_PLL_DIV(0) | Ratio MIPS Core Clock Rate : System Bus Clock Rate (hclk) | System Bus Clock (hclk) Duty Cycle |
|----------------|----------------|-----------------------------------------------------------|------------------------------------|
| 0              | X              | 2:1                                                       | 50%                                |
| 1              | 1              | 3:1                                                       | 33% <sup>a</sup>                   |
| 1              | 0              | 4:1                                                       | 50%                                |

a. In 3:1 mode, the System bus clock duty cycle is not symmetric. This affects the internal System Bus clock as well as hclk and the SDRAM clock source (SD\_CLKOUT). Therefore, care must be taken so that minimum clock pulse widths are not violated when these clock signals are used to drive externally connected devices.

## SDRAM Memory Controller

The QL903M SDRAM Memory Controller (SDMC) provides all the necessary logic to connect to a wide variety of industry standard SDRAMs for use by the CPU, Ethernet Controllers, PCI Controller, and Programmable Fabric. The SDMC supports a minimum SDRAM size of 16 Mbytes and a maximum SDRAM size of 256 Mbytes.

The SDRAM Controller controls the SDRAM on the external bus. On receiving an access request, the SDRAM Controller decides on the appropriate commands to send to the SDRAM memory. The DRAM Bank Controller sequences all of the commands required to complete a read or write request to an SDRAM memory location with timing controlled by the CAS Delay and RAS Delay values.

The bus interface is a slave on the System Bus; it contains the control register block. The bus interface produces read, write, refresh and mode register write requests to the SDRAM control engine, and software supplied configuration information.

Data is transferred to and from the SDRAM as unbroken quad words. This data packet size is convenient for cache line fills and buffered writes. For accesses smaller than a quad word, extra read data is ignored by the SDRAM Controller; for writes, the SD\_DQM(3:0) pins are used to force the SDRAMs to ignore invalid data. For access sizes larger than a quad word, multiple quad word accesses are issued to the SDRAM control engine.

## I/O Peripheral Controller

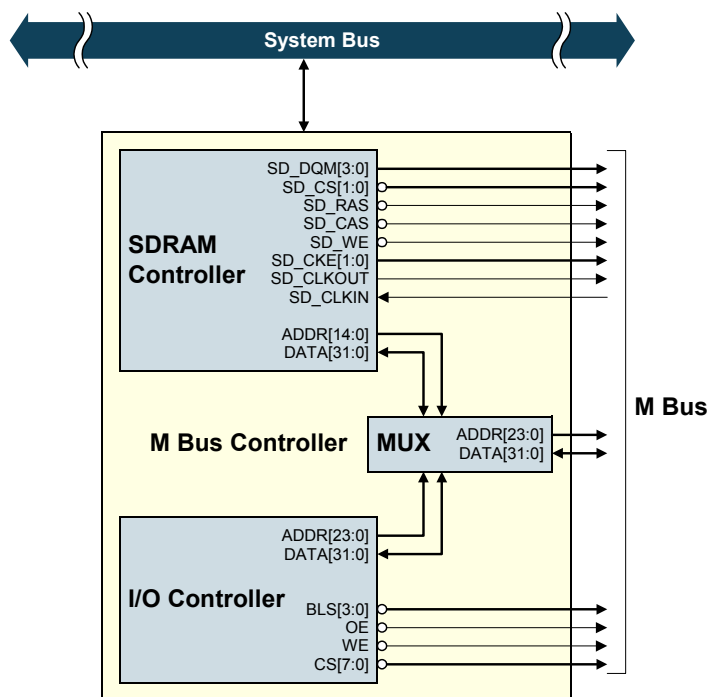

This section describes access to I/O and memory devices on the external M Bus (with the exception of SDRAM). The I/O Peripheral Controller (**Figure 2**) generates strobes and signals that can be used to interface the M Bus with common asynchronous peripheral devices.

The QL903M Peripheral Controller Unit (PCU) provides decoded strobe signals to control external peripherals such as SRAM, flash, real time clock (RTC) and memory mapped I/O devices. It supports 8-bit, 16-bit, and 32-bit widths with programmable wait states and bus turnaround time based on memory speed. The PCU provides the following functionality:

- Decoding of memory access in the local CPUs memory map to generate chip selects or strobes.
- Control of wait states for decoded regions. A total of eight chip select signals are available. Chip select seven is used as the boot ROM chip select.

The M Bus is a shared resource between the SDRAM Controller and I/O Controller. The M Bus is assigned to one of these two controllers by an internal arbiter. There is one turn-around cycle when switching from one controller to the other.

Figure 2: SDRAM and I/O Controllers

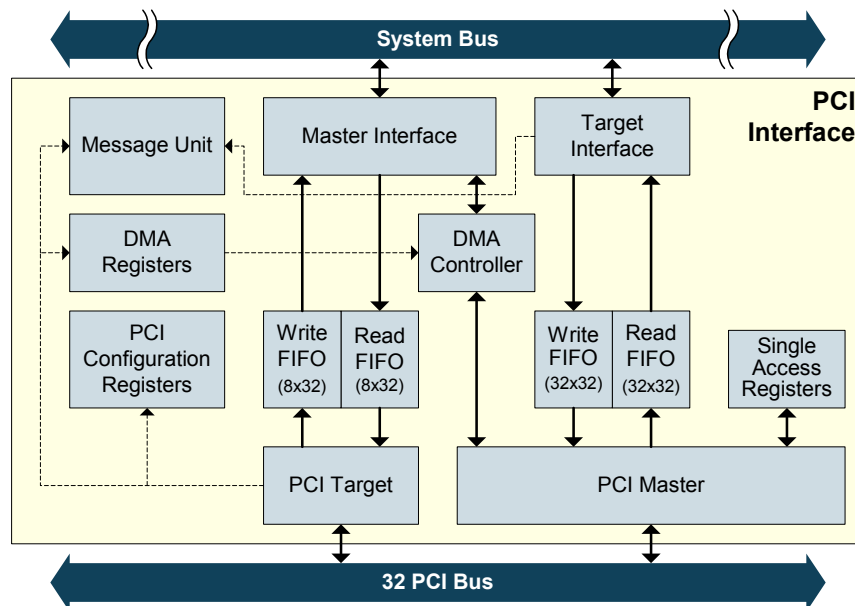

## PCI Controller

The QuickMIPS PCI Interface is a 32-bit, 66 MHz, Revision 2.2 compliant interface as specified by the PCI Local Bus Specification. This section provides a detailed description of the PCI Controller functionality.

**Figure 3** shows a simplified block diagram of the PCI Controller. The PCI Controller is a bridge between the on-chip System Bus and the external PCI bus. There are two main modes of operation of the PCI function, each utilizing several resources:

- PCI Target
  - PCI Target access to System Address Space
  - PCI Target to PCI configuration registers
  - PCI Target to extended registers (DMA and message/mailbox)
- PCI Master
  - System Address Space to PCI access
  - System-to-PCI and PCI-to-System DMA
  - PCI master read/write generated through the single access register

Figure 3: PCI Block Diagram

The PCI Controller can be used as a system host or as a secondary master:

- System Host: The QL903M PCI interface is connected to the root PCI bus segment (Bus 0) and the on-chip CPU performs bus enumeration to determine how all PCI Base Address Registers are configured. The SDRAM controlled by the QL903M is used as the main memory.
  - The Single Access Controller can be used for performing enumeration upon system boot, and then to perform I/O operations to I/O mapped PCI devices.
  - The System Bus to PCI Memory Aperture can be used by host drivers to control memory mapped PCI devices (PIO).
  - The DMA Controller provides the most efficient way to transfer large blocks of data between system memory and external PCI target devices (such as video controllers, etc.).
- Secondary Master: The QL903M is enumerated by an external PCI host CPU.
  - The PCI configuration registers of the QL903M are recognized by the host CPU and enumerated accordingly.
  - The DMA Controller can be used to efficiently move data between local QL903M-controlled SDRAM and the host memory.
  - The Single Access Controller can be used to transfer small amounts of data in and out of the host memory space.
  - The message unit can be used as an inter-CPU communication mechanism for a host driver to synchronize with a local driver running on the QL903M CPU.
  - The PCI to local System Bus aperture can be used to allow the host CPU or other PCI agent to access QL903M memory directly.

## Ethernet Controllers

The QL903M has two Ethernet Media Access Controllers (MACs) embedded in the ASSP portion of the device. The Ethernet Controllers incorporate the essential protocol requirements for operation of Ethernet/IEEE 802.3 compliant nodes, and provide interfaces between the host subsystem and the Media Independent Interface (MII). Each 10/100 MAC can operate in 10 Mbps or 100 Mbps mode based on the transmit and receive clocks provided (2.5/25 MHz). The controllers contain transmit and receive FIFOs and embedded DMA control. **Figure 4** shows a block diagram of the QL903M Ethernet Controller.

Figure 4: Ethernet Controller Block Diagram

The DMA Controller is responsible for exchanging data between the FIFOs and the system memory. DMA operation is controllable through a set of control and status registers.

Each 10/100 MAC operates in half-duplex mode and full-duplex modes. When operating in the half-duplex mode, the 10/100 MAC core is fully compliant to Section 4 of ISO/IEC 8802-3 (ANSI/IEEE Standard) and ANSI/IEEE 802.3. When operating in the full-duplex mode, the 10/100 MAC core is compliant to the IEEE 802.3x standard for full-duplex operations. Each 10/100 MAC is also compatible with Home PNA 1.1.

The 10/100 MAC core provides programmable enhanced features designed to minimize host supervision, bus utilization, and pre- or post-message processing. These features include the ability to disable retries after a collision, dynamic FCS generation on a frame-by-frame basis, automatic pad field insertion and deletion to enforce minimum frame size attributes, automatic retransmission and detection of collision frames.

The 10/100 MAC core can sustain transmission or reception of minimal-sized back-to-back packets at full line speed with an inter-packet gap (IPG) of 9.6  $\mu$ s for 10-Mb/s and 0.96  $\mu$ s for 100-Mb/s.

Data to/from the MAC is buffered in transmit/receive FIFOs. In the case of data received by the Ethernet MAC, the data is drained from the receive FIFO by the DMA Controller and stored to the specified target (typically the data is stored in SDRAM). For Ethernet transmit, the DMA Controller reads data from memory (SDRAM typically) and pushes it into the transmit FIFO. DMA operation is controllable through a set of control and status registers.

With the exception of the M1\_RXCLK, M2\_RXCLK, M1\_TXCLK and M2\_TXCLK signals, the MII interface is located on the ASSP/Fabric boundary internal to the device. If the designer wants to use one or both of the Ethernet MACs, the signal ports on this interface must be brought out to Fabric IO pins in the top-level Fabric design. **Table 3** shows the recommended Fabric IO pin locations for the MII interface pins.

Table 3: MII Interface Signals and Recommended Fabric IO Pin Locations

| MII Interface Signal | MII Interface Direction <sup>a</sup> | Fabric Pin Signal    | Fabric Pin Type | Fabric Pin Location |
|----------------------|--------------------------------------|----------------------|-----------------|---------------------|
| M1_COL               | I                                    | M1_COL               | I               | F1                  |
| M1_CRS               | I                                    | M1_CRS               | I               | G2                  |
| M1_MDC               | O                                    | M1_MDC               | O               | F3                  |
| M1_MDI               | I                                    | M1_MDIO <sup>b</sup> | I/O/Z           | K4                  |
| M1_MDO               | O                                    |                      |                 |                     |
| M1_MDO_EN_N          | O                                    |                      |                 |                     |
| M1_RXD(0)            | I                                    | M1_RXD(0)            | I               | F2                  |
| M1_RXD(1)            | I                                    | M1_RXD(1)            | I               | E1                  |
| M1_RXD(2)            | I                                    | M1_RXD(2)            | I               | E2                  |
| M1_RXD(3)            | I                                    | M1_RXD(3)            | I               | D1                  |
| M1_RXDV              | I                                    | M1_RXDV              | I               | L4                  |
| M1_RXER              | I                                    | M1_RXER              | I               | D2                  |
| M1_TXD(0)            | O                                    | M1_TXD(0)            | O               | L3                  |
| M1_TXD(1)            | O                                    | M1_TXD(1)            | O               | C1                  |
| M1_TXD(2)            | O                                    | M1_TXD(2)            | O               | L5                  |
| M1_TXD(3)            | O                                    | M1_TXD(3)            | O               | B1                  |
| M1_TXEN              | O                                    | M1_TXEN              | O               | E3                  |
| M2_COL               | I                                    | M2_COL               | I               | K22                 |
| M2_CRS               | I                                    | M2_CRS               | I               | L24                 |
| M2_MDC               | O                                    | M2_MDC               | O               | C25                 |
| M2_MDI               | I                                    | M2_MDIO <sup>b</sup> | I/O/Z           | E25                 |
| M2_MDO               | O                                    |                      |                 |                     |
| M2_MDO_EN_N          | O                                    |                      |                 |                     |
| M2_RXD(0)            | I                                    | M2_RXD(0)            | I               | B26                 |
| M2_RXD(1)            | I                                    | M2_RXD(1)            | I               | L23                 |
| M2_RXD(2)            | I                                    | M2_RXD(2)            | I               | E24                 |
| M2_RXD(3)            | I                                    | M2_RXD(3)            | I               | C24                 |
| M2_RXDV              | I                                    | M2_RXDV              | I               | F24                 |
| M2_RXER              | I                                    | M2_RXER              | I               | L22                 |
| M2_TXD(0)            | O                                    | M2_TXD(0)            | O               | M24                 |
| M2_TXD(1)            | O                                    | M2_TXD(1)            | O               | C26                 |
| M2_TXD(2)            | O                                    | M2_TXD(2)            | O               | M23                 |
| M2_TXD(3)            | O                                    | M2_TXD(3)            | O               | D26                 |
| M2_TXEN              | O                                    | M2_TXEN              | O               | M22                 |

a. MII Interface direction is specified with respect to the ASSP portion of the device. I designates an input to the ASSP and O designates an output from the ASSP.

b. The M1\_MDIO and M2\_MDIO signals require the instantiation of a bipad\_25um macro. See [Figure 5](#) for more details.

The pin assignments in **Table 3** represent connections to IO banks A and D of the Fabric. If the Ethernet MACs are connected in this fashion, these two banks must be configured for 3.3 V operation. See **Table 17** for more details.

As **Table 3** indicates, the Mn\_MDIO pin is bi-directional. The signal on this pin is made up of three MII interface signals. Mn\_MDI and Mn\_MDO are the data input and output signals respectively, and Mn\_MDO\_EN\_N is the tri-state buffer enable signal that turns on the pin output driver. Mn\_MDO\_EN\_N is active low, and must be made active high by running it through a logic cell inverter before connecting it to the bipad\_25um macro. **Figure 5** shows how these connections are made to the bipad\_25um macro.

Figure 5: bipad\_25um Macro and Connections to MII Interface Signals

The remainder of the MII signals are simple inputs or outputs and can be connected to the Fabric IO pins directly without the instantiation of any specific macros.

## System SRAM

The QL903M contains 16 K bytes of SRAM internal to the ASSP portion of the device. This SRAM is divided into four equal sections of 4 KB each (each arranged as 32-bit x 1024 words), and each section can be configured to be connected to the System Bus (specifically, AHB) or connected to the Fabric directly.

When connected to the AHB, the SRAM (an AHB slave) can be accessed by any AHB master. Furthermore, the 4Kc core can use this internal SRAM for data or instruction storage. The SRAM supports 32-bit, 16-bit, or single byte accesses.

When connected to the Fabric, the SRAM can be accessed directly by any Fabric design without suffering the overhead of accessing it through the AHB interface. In addition, the Fabric has a master AHB interface, which it may also use to access the SRAM. However, in some high-speed applications, it may be necessary for the Fabric to have exclusive access to the SRAM memory. The Fabric interface of the SRAM block facilitates this function, and is described below. **Figure 6** shows the connection scheme of the four memory banks between the Fabric and the AHB.

Figure 6: SRAM Connection Scheme between the Fabric and AHB

Each SRAM block is single ported, and is connected to the Fabric or AHB through a selection MUX. For each SRAM block, the address bus, control signals, clock, and data write bus are all multiplexed by a register bit that is accessible through the System Bus. Therefore, any AHB master may control the switch of a given SRAM block between the AHB and the Fabric interface.

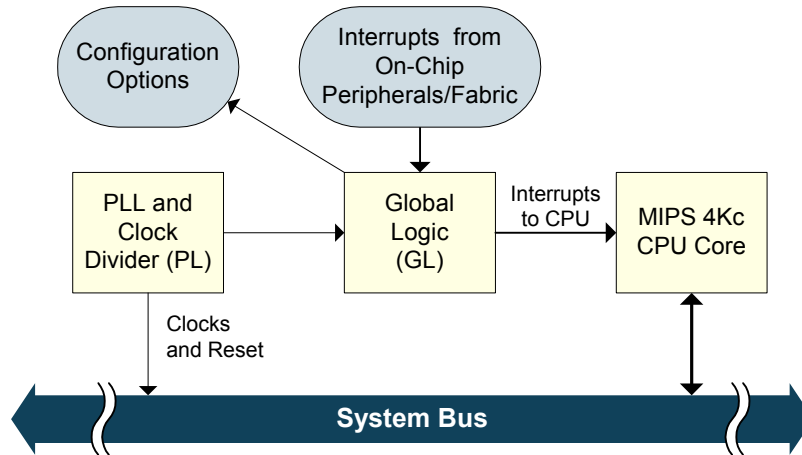

Because each SRAM clock is also switched by the selection MUX, it is possible for the Fabric to drive each SRAM block with a separate clock. However, when an SRAM block is connected to the AHB interface, the System Bus clock (hclk) is always used to drive the block.

Refer to **Table 51** for descriptions of all the System SRAM signals that interface to the Fabric.

## Interrupt Controller

This section describes the function of the QL903M Interrupt Controller Unit (ICU). **Figure 7** shows a block diagram of the Interrupt Controller.

Figure 7: Simplified Interrupt Controller Block Diagram

The QL903M has 9 on-chip peripheral interrupts and 7 external interrupts (including on NMI), for a total of 16 interrupt sources. These 16 interrupt sources are combined into 7 interrupts by the interrupt controller and fed to the CPU core.

External interrupts must be asserted for at least two clock periods in order to be recognized as an interrupt. All interrupts are level triggered.

Each interrupt has an Emulation Enable Register bit and an Emulation Interrupt Value Register bit in the Interrupt Controller. The primary use for the Emulation registers is for testing purposes. The interrupt enable bits are stored in the GL\_EMUL\_EN register. The emulation interrupt value for each possible interrupt is stored in the GL\_INT\_EMUL register.

Each interrupt has an enable bit in the Global Individual Interrupt Enable (GL\_IND\_INT\_EN) register in the Interrupt Controller. Each interrupt also has a status bit in the Global Individual Interrupt Status (GL\_IND\_INT\_STATUS) register in the Interrupt Controller.

The Global CPU Interrupt Enable register (GL\_CPU\_INT\_EN) enables masking of the interrupt groups after they have been grouped together.

The Interrupt Controller has no programmability for priority. That is, there is no hardware priority encoder. Priority is provided as a function of software.

## High Performance 32-Bit System Bus (AMBA Bus)

The purpose of this section is to describe the AMBA<sup>1</sup> bus operation for the purposes of implementing user circuits in the Programmable Fabric. All circuits in the ASSP portion of the QL903M chip communicate with the Programmable Fabric primarily through the AMBA bus interfaces (Advanced Microcontroller Bus Architecture from ARM). Circuits implemented in the Programmable Fabric must be designed according to the AMBA Specification, Revision 2.0. The devices within the QL903M are interconnected through the Advanced High-performance Bus (AHB) or the Advanced Peripheral Bus (APB). Refer to the AMBA Specification, Revision 2.0, for more detailed information about the AHB and APB.

### Advanced High-Performance Bus (AHB)

The AHB is the high-performance variant of the AMBA specification. It supports multiple bus masters and provides high bandwidth operation. The AHB implementation in the QL903M is 32 bits wide. All signals are synchronous to the rising clock edge of the bus clock (hclk).

The key features of the QL903M AHB include:

- Burst transfers
- Single-cycle bus master handover
- 32-bit bus runs at up to half the CPU clock frequency
- Multiple bus masters
- Arbitration through an AHB arbiter
- Address decoding through an AHB decoder

**Table 4** lists the master and slave devices that connect to the AHB.

Table 4: Master and Slave Devices on the AHB

| AHB Masters                                    | AHB Slaves                                    |
|------------------------------------------------|-----------------------------------------------|
| MIPS 4Kc CPU                                   | System SRAM                                   |
| PCI                                            | PCI                                           |
| Ethernet Controller 1                          | Ethernet Controller 1                         |
| Ethernet Controller 2                          | Ethernet Controller 2                         |
| 32-bit Master Interface to Programmable Fabric | 32-bit Slave Interface to Programmable Fabric |
|                                                | SDRAM and I/O Peripheral Controllers          |
|                                                | Interrupt Controller                          |
|                                                | AHB to APB Bridge                             |

The QL903M AHB supports multiple bus masters as well as bus slaves. Only one bus master can use the bus at a given time. The bus master provides address and control information when performing read and write operations. In response to the read or write operation from the bus master within a given address range, a bus slave provides information regarding the status of the data transfer (success, failure, or wait). The AHB arbiter ensures that only one bus master is initiating data transfers. The AHB decoder decodes the address of each transfer and provides a select signal for the slave that is involved in the transfer.

1. AMBA is a trademark of ARM Ltd.

## AHB Arbitration

The internal arbiter of the QL903M provides either fixed arbitration priority or round robin rotating priority. Preemption occurs only after a burst of four. Consequently, when a low priority master is in control of the bus and a higher priority master requests access, the lower priority device will lose its grant after a burst of four before another master takes control. This minimizes the loss of performance that happens when bursts are preempted.

This preemption only happens when the designated AHB master is performing bursts of undefined lengths. If the AHB master is performing a burst of a defined (fixed) length, the burst will complete without interruption by the arbiter.

The ARB\_FAIR\_EN bit in the GL\_INT\_EMUL register determines the priority scheme.

When fixed priority is chosen, the priority of AHB masters is as follows (highest to lowest):

1. MIPS 4Kc CPU
2. Ethernet Controller 1
3. Ethernet Controller 2
4. PCI Controller
5. Programmable Fabric

## Advanced Peripheral Bus (APB)

The APB is a simplified bus that is ideal for implementing device control registers and other non-burst transfers. The APB is a 32-bit wide bus that runs at the same frequency as AHB. The APB only accommodates slaves, does not support burst transfers, and does not support advanced slave response operations such as retries or wait state insertion. The APB on the QL903M is supported through an AHB-to-APB bridge. Three separately decoded APB regions are available for APB devices implemented in the Fabric. **Table 5** lists the slave devices on the APB.

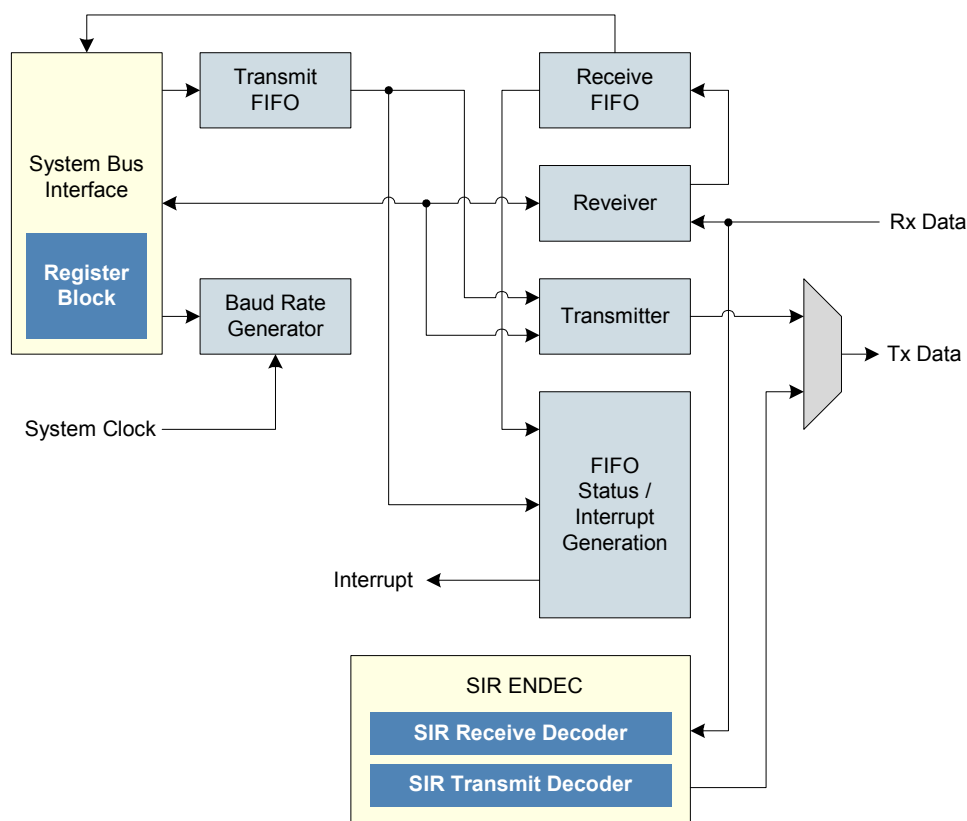

Table 5: Slave Devices on the APB

| APB Slaves                                           |
|------------------------------------------------------|
| Two UARTs                                            |
| Four 16-bit Timers/Counters                          |
| Three 32-bit slave interfaces to Programmable Fabric |

## UARTs

The QL903M chip contains two UARTs. Each UART provides a full-duplex asynchronous receiver and transmitter and has programmable Baud rates. The UARTs contain an IrDA Serial Infrared (SIR) Encoder/Decoder (ENDEC). One UART also has modem control signals. The serial output is software selectable between IrDA and generic serial modes. **Figure 8** shows a block diagram of the UART.

Figure 8: UART Block Diagram

The key features of the UARTs are as follows:

- Programmable Baud rate generation of up to 1/16 System Bus clock rate
- FIFO enable or disable
- 5, 6, 7, or 8 data bits
- 1 or 2 stop bits
- Odd and even, stick or no parity
- Parity, framing, and overrun error detection
- Line break generation and detection
- Loopback
- Interrupt generation

- IrDA SIR ENDEC block providing:
  - Programmable use of IrDA SIR or UART input/output
  - Support of IrDA SIR ENDEC functions for data rates up to 115.2 kilobits/second half-duplex
  - Support of normal 3/16 and low-power (1.41 to 2.23μs) bit durations
  - Programmable internal clock generator allowing division of reference clock by 1 to 512 for low-power mode bit duration

The System Bus (APB interface) generates read and write decodes for accesses to status/control registers and transmit/receive FIFO memories. The Register Block stores data written or to be read across the APB interface. The Baud Rate Generator contains free-running counters that generate a clock that is 16 times the transmit/receive bit rate.

The transmit FIFO is an 8-bit wide, 16-entry deep FIFO memory buffer. CPU data written across the APB interface is stored in the FIFO until read out by the transmit logic. The transmit FIFO can be disabled to act like a one-byte holding register. The receive FIFO is a 12-bit wide, 16-entry deep FIFO memory buffer. Received data and corresponding error bits, are stored in the receive FIFO by the receive logic until read out by the CPU across the APB interface. The receive FIFO can be disabled to act like a one-byte holding register.

The transmitter performs parallel-to-serial conversion on the data read from the transmit FIFO. Control logic outputs the serial bit stream beginning with a start bit, data bits, Least Significant Bit (LSB), a parity bit, and then stop bits according to the programmed configuration in control registers. The receiver performs serial-to-parallel conversion on the received bitstream after a valid start pulse has been detected. Overrun, parity, frame error checking, and line break detection are also performed, and the data with associated overrun, parity, framing, and break error bits is written to the receive FIFO.

The Interrupt Generator outputs a single, combined interrupt to the QL903M Interrupt Controller.

The SIR Transmit Encoder modulates the Non-Return-to-Zero (NRZ) transmit bitstream output from the QL903M chip. The IrDA SIR physical layer specifies use of a Return To Zero, Inverted (RZI) modulation scheme that represents logic 0 as an infrared light pulse. The modulated output pulse stream is transmitted to an external output driver and infrared Light Emitting Diode (LED).

The SIR Receive Decoder demodulates the return-to-zero bit stream from the infrared detector and outputs the received NRZ serial bitstream to the QL903M UART received data input. The decoder input is normally HIGH (marking state) in the idle state. The transmit encoder output has the opposite polarity to the decoder input.

## General Purpose 16-bit Timer/Counters

The QL903M chip has four independent 16-bit timer/counter modules. The configuration registers for these modules are accessible through the System Bus (APB).

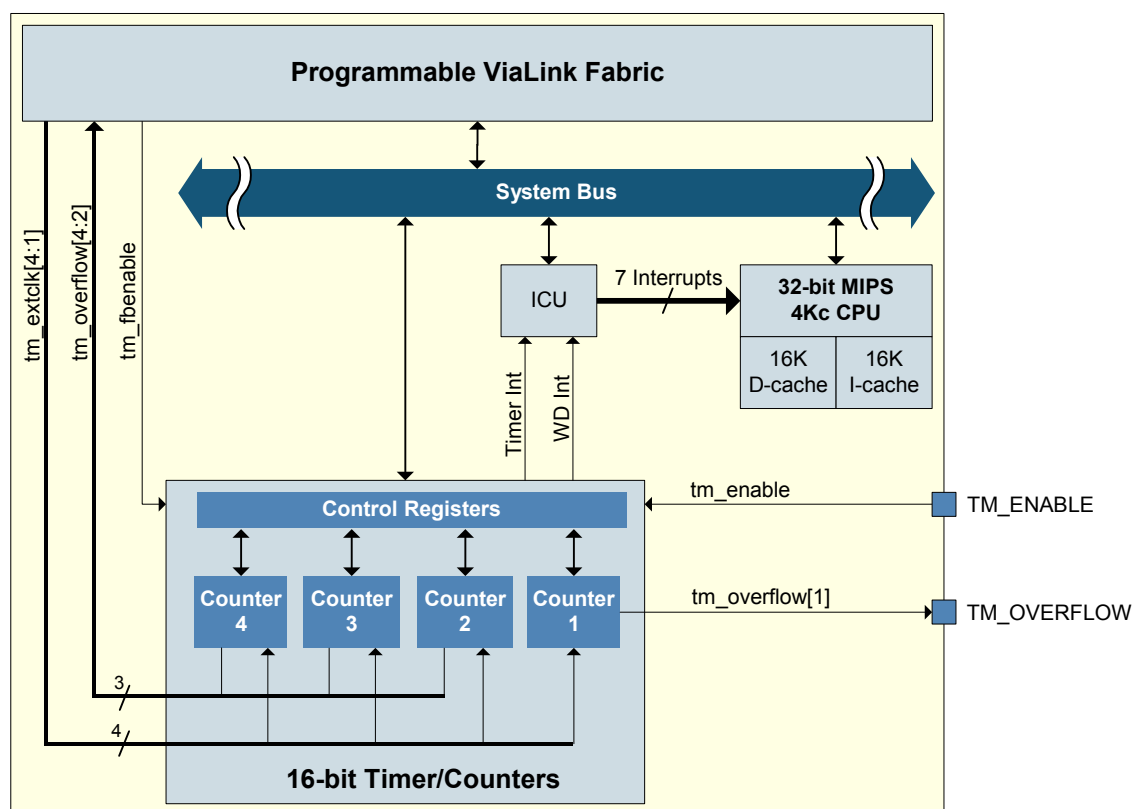

The System Bus clock (hclk), or an external clock supplied from the Fabric, drive the clock inputs on the timer/counter modules. These counters operate in one of four modes: decrement, increment, interval, or Pulse Width Modulation (PWM).

Each timer/counter module has the capability to generate system interrupts on various events.

One timer/counter is configured, by default, as a watchdog timer after a system reset. This watchdog timer has its own system interrupt output.

**Figure 9** shows a functional block diagram of the timer module.

Figure 9: Timer Functional Block Diagram

The key features of each timer/counter module are as follows:

- Up to 100 MHz operation.
- 32-bit data path on the System Bus.
- 16-bit timer/counter.
- 16-bit pre-scaler to increase timer/counter delay.
- Four modes of operation: decrement, increment, interval and PWM.
- Operation from the System Bus clock (hclk) or an external clock from the Fabric.
- Two external hardware timer enable signals can be used to start/stop the timer/counter. One of these signals can be supplied from the Fabric and the other is a dedicated input pin on the chip.
- Three match interrupts, one interval interrupt and one overflow interrupt.
- Six control registers to control various counter functions, including enable/disable, load, and reset.

The timer/counters are controlled by a set of control registers. Each timer/counter module has six control registers. By contrast, one interrupt register is used to control and convey the status of the interrupts from all the modules.

One counter (Counter 4) is configured, by default, to be used as a watchdog timer after the system reset. This watchdog timer has its own system interrupt output, and it can be reconfigured by software for use as a standard timer/counter.

## Fabric Side

This section discusses the various circuit elements in the Fabric portion of the QL903M device.

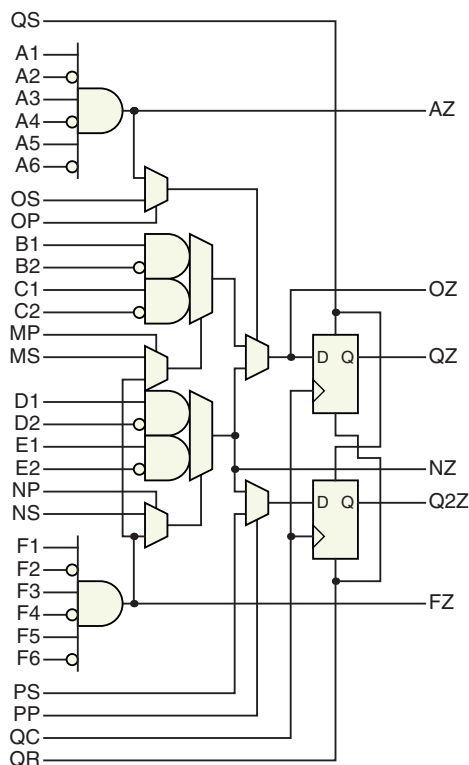

### Logic Cells

The QL903M logic cell structure presented in **Figure 10** is a dual register, multiplexor-based logic cell. It is designed for wide fan-in and multiple, simultaneous output functions. Both registers share CLK, SET, and RESET inputs. The second register has a two-to-one multiplexer controlling its input. The register can be loaded from the NZ output or directly from a dedicated input.

**NOTE:** The input PP is not an “input” in the classical sense. It is a static input to the logic cell and selects which path (NZ or PS) is used as an input to the Q2Z register. All other inputs are dynamic and can be connected to multiple routing channels.

The complete logic cell consists of two 6-input AND gates, four two-input AND gates, seven two-to-one multiplexers, and two D flip-flops with asynchronous SET and RESET controls. The cell has a fan-in of 30 (including register control lines), fits a wide range of functions with up to 17 simultaneous inputs, and has six outputs (four combinatorial and two registered). The high logic capacity and fan-in of the logic cell accommodates many user functions with a single level of logic delay while other architectures require two or more levels of delay.

Figure 10: QL903M Logic Cell

## Dual-Port SRAM Modules

The QL903M includes up to 18 dual-port 2,304-bit RAM modules (shown in **Figure 11**) for implementing RAM, ROM, and FIFO functions. Each module is user-configurable into two different block organizations and can be cascaded vertically to increase their effective depth or horizontally to increase their effective width as shown in **Figure 12**.

Figure 11: 2,304-bit RAM Module

Using two *mode* pins, designers can configure each module into 128 x 18 (Mode 0) or 256 x 9 (Mode1).

Figure 12: Cascaded RAM Modules

The RAM modules are dual-port, with completely independent READ and WRITE ports and separate READ and WRITE clocks. The READ ports support asynchronous and synchronous operation, while the WRITE ports support synchronous operation. Each port has 18 data lines and 8 address lines, allowing word lengths of up to 18 bits and address spaces of up to 256 words. Depending on the mode selected, however, some higher order data lines or the highest order address line may not be used.

The Write Enable (WE) line acts as a clock enable for synchronous write operation. The Read Enable (RE) acts as a clock enable for synchronous READ operation (ASYNCRD input low). The RE and RCLK inputs are ignored when ASYNCRD is tied high.

Designers can cascade multiple RAM modules to increase the depth or width allowed in single modules by connecting corresponding address lines together and dividing the words between modules.

A similar technique can be used to create depths greater than 256 words. In this case address signals higher than the eighth bit are encoded onto the write enable (WE) input for WRITE operations. The READ data outputs are multiplexed together using encoded higher READ address bits for the multiplexer SELECT signals.

The RAM blocks can be loaded with data generated internally (typically for RAM or FIFO functions) or with data from an external PROM (typically for ROM functions).

### Dual-Port SRAM Module Signals

The dual-port RAM module signal descriptions are shown in **Table 6**.

Table 6: Dual-Port RAM Module Signal Descriptions

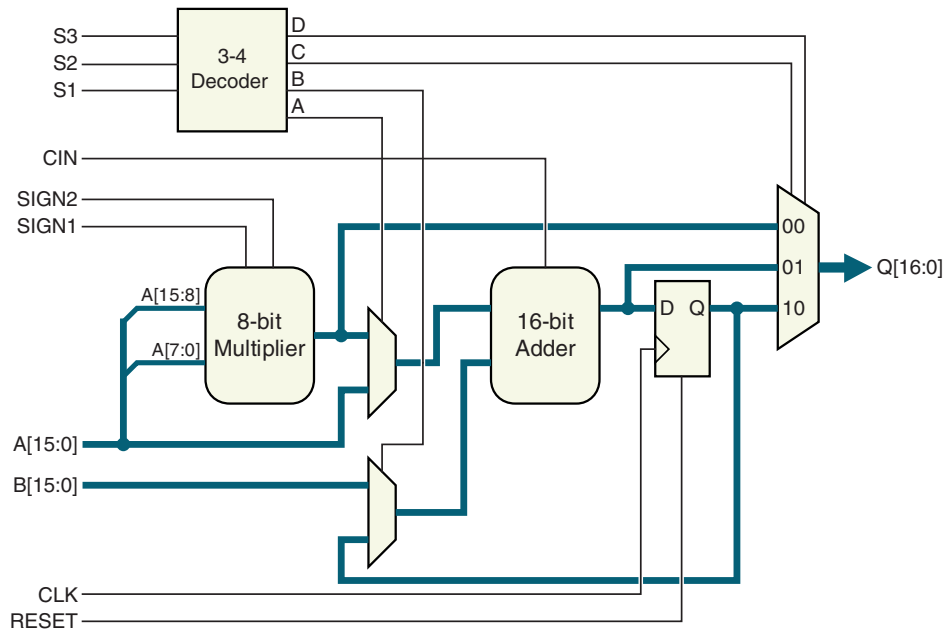

| Signal Name | I/O | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| WCLK        | I   | <b>Write Clock.</b> Clock input for the write port of the RAM module. All write port input signals are synchronous with this clock.                                                                                                                                                                                                                                                                                                                                                                                              |
| WE          | I   | <b>Write Enable.</b> Sampled on the rising edge of WCLK, when WE is high, data is written into the RAM module at the specified write address.                                                                                                                                                                                                                                                                                                                                                                                    |
| WA(7:0)     | I   | <b>Write Address.</b> Sampled on the rising edge of WCLK, this is the write address for the data to be written into the RAM module. WA(7:0) is ignored when WE is low. Note that some higher order bits of WA(7:0) may not be used depending on the selected mode for the RAM module (see MODE(1:0) signal description).                                                                                                                                                                                                         |
| WD(17:0)    | I   | <b>Write Data.</b> Sampled on the rising edge of WCLK, this is the data to be written into the RAM module. WD(17:0) is ignored when WE is low. Note that some higher order bits of WD(17:0) may not be used depending on the selected mode for the RAM module (see MODE(1:0) signal description).                                                                                                                                                                                                                                |
| RCLK        | I   | <b>Read Clock.</b> This is the clock input for the read port of the RAM module. If ASYNCRD is low, all read port I/O signals are synchronous with this clock. If ASYNCRD is high, RCLK is ignored.                                                                                                                                                                                                                                                                                                                               |
| RE          | I   | <b>Read Enable.</b> Sampled on the rising edge of RCLK, when RE is high, data is read from the RAM module at the specified read address. If ASYNCRD is high, this RE is ignored.                                                                                                                                                                                                                                                                                                                                                 |
| RA(7:0)     | I   | <b>Read Address.</b> This is the read address for data to be read from the RAM module. If ASYNCRD is low, RA(7:0) is sampled only on the rising edge of RCLK while RE is high. If ASYNCRD is high, RA(7:0) is continuously sampled by the RAM module and RE has no effect. Note that some higher order bits of RA(7:0) may not be used depending on the selected mode for the RAM module (see MODE(1:0) signal description).                                                                                                     |
| RD(17:0)    | O   | <b>Read Data.</b> This is the read output data from the RAM module. If the RAM module is in synchronous read mode (ASYNCRD low), valid read data is output immediately following the rising edge of RCLK which sampled RE as high. If the RAM module is in asynchronous read mode (ASYNCRD high), valid read data is output immediately after any change in the read address. Note that some higher order bits of RD(17:0) may not be used depending on the selected mode for the RAM module (see MODE(1:0) signal description). |
| ASYNCRD     | I   | <b>Asynchronous Read Input.</b> This signal, when high, indicates to the RAM block that the read port should operate asynchronously. When low, all read port I/O signals are synchronous with RCLK. This signal can only be tied to '1' or '0' inside the Fabric.                                                                                                                                                                                                                                                                |
| MODE(1:0)   | I   | <b>Mode for RAM Module.</b> These bits configure the width and depth of the RAM module (for both the read and write ports) and can only be tied to '1' or '0' inside the Fabric. The possible RAM module modes are:<br>MODE(1:0) = "00" : 128 x 18 (locations x data bits)<br>MODE(1:0) = "01" : 256 x 9 (locations x data bits)<br>MODE(1:0) = "1X" : Reserved                                                                                                                                                                  |

## Embedded Computational Units (ECUs)

Traditional Programmable Logic architectures do not implement arithmetic functions efficiently or effectively—these functions require high logic cell usage while garnering only moderate performance results.

The QL903M architecture allows for functionality above and beyond that achievable using programmable logic devices. By embedding a dynamically reconfigurable computational unit, the QL903M device can address various arithmetic functions efficiently. This approach offers greater performance than traditional programmable logic implementations. The embedded block is implemented at the transistor level as shown in **Figure 13**.

Figure 13: ECU Block Diagram

## ECU Signals

**Table 7** defines the ECU I/O signals. For more information on the operation of the ECU, see QuickLogic Application Note 52 at <http://www.quicklogic.com/images/appnote52.pdf>.

Table 7: ECU I/O Signals

| Signal Name | I/O | Description                                                                                                                                                                  |
|-------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| CLK         | I   | <b>Clock Input.</b> Input clock for the ECU output register.                                                                                                                 |
| RESET       | I   | <b>Reset Input.</b> Active high reset input for the ECU output register.                                                                                                     |
| S1          | I   | <b>ECU Control S1.</b> One of three instruction signals that define the configuration mode of the ECU (see <b>Table 8</b> ).                                                 |
| S2          | I   | <b>ECU Control S2.</b> One of three instruction signals that define the configuration mode of the ECU (see <b>Table 8</b> ).                                                 |
| S3          | I   | <b>ECU Control S3.</b> One of three instruction signals that define the configuration mode of the ECU (see <b>Table 8</b> ).                                                 |
| CIN         | I   | <b>Carry Input.</b> 1-bit Carry In for 16-bit adder operations.                                                                                                              |
| SIGN1       | I   | <b>Sign Input for Multiplier A Input.</b> When SIGN1 = '1', A(7:0) is treated as signed or two's complement binary. When SIGN1 = '0' A(7:0) is treated as unsigned binary.   |
| SIGN2       | I   | <b>Sign Input for Multiplier B Input.</b> When SIGN2 = '1', B(15:8) is treated as signed or two's complement binary. When SIGN2 = '0' B(15:8) is treated as unsigned binary. |
| A(15:0)     | I   | <b>Augend Input.</b> 16-bit augend input of the 16-bit adder when the ECU is in any of the adder configuration modes.                                                        |
| A(15:8)     |     | <b>Multiplicand Input.</b> 8-bit multiplicand input when the ECU is in any of the multiplier configuration modes.                                                            |
| A(7:0)      |     | <b>Multiplier Input.</b> 8-bit multiplier input when the ECU is in any of the multiplier configuration modes.                                                                |
| B(15:0)     | I   | <b>Addend Input.</b> 16-bit addend input when ECU is in any of the adder configuration modes.                                                                                |
| Q(16:0)     | O   | <b>ECU Output.</b> This is the 17-bit output of the ECU. The interpretation of the value of Q(16:0) depends on the setting of S1, S2, S3, SIGN1, and SIGN2.                  |

The QL903M ECU blocks are placed next to the SRAM circuitry for efficient memory/instruction fetch and addressing for DSP algorithmic implementations.

Up to eighteen 8-bit MAC functions can be implemented per cycle for a total of 1.8 billion MACs/s when clocked at 100 MHz. Additional multiply-accumulate functions can be implemented in the programmable logic.

The instruction modes for the ECU block are dynamically re-programmable through the programmable logic as shown in **Table 8**.

Table 8: ECU Mode Select Criteria

| Instruction |    |    | Operation                          |
|-------------|----|----|------------------------------------|
| S1          | S2 | S3 |                                    |
| 0           | 0  | 0  | Multiply                           |
| 0           | 0  | 1  | Multiply-Add                       |
| 0           | 1  | 0  | Accumulate                         |
| 0           | 1  | 1  | Add                                |
| 1           | 0  | 0  | Multiply (registered) <sup>a</sup> |
| 1           | 0  | 1  | Multiply- Add (registered)         |
| 1           | 1  | 0  | Multiply - Accumulate              |
| 1           | 1  | 1  | Add (registered)                   |

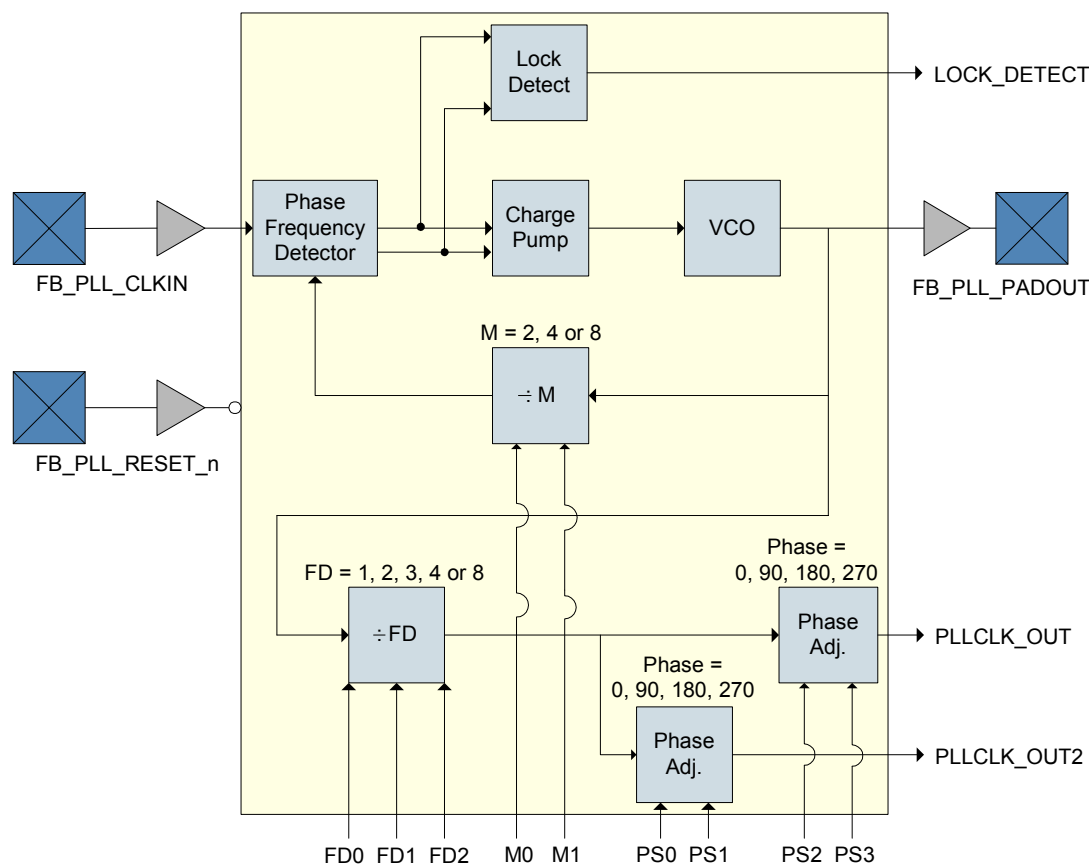

a. B (15:0) set to zero.

## Fabric PLL

Instead of requiring extra components, designers simply need to instantiate the QL903M Fabric PLL model (described in this section). The Fabric PLL built into the QL903M supports a wider range of frequencies than many other PLLs. The PLL also has the ability to support different ranges of frequency multiplications or divisions, driving the Fabric at a faster or slower rate than the incoming clock frequency.

**Figure 14** illustrates the QL903M Fabric PLL.

Figure 14: QL903M Fabric PLL Block Diagram

The QL903M Fabric PLL is driven by the FB\_PLL\_CLKIN input pin. This input is used by the PLL as a clock reference for the Voltage Controlled Oscillator (VCO) internal to the PLL circuit. Using the M1 and M0 inputs to the PLL block, the designer may choose a frequency multiplier value for the VCO. The PLL output pin, FB\_PLL\_PADOUT runs at the VCO operational frequency. **Table 9** shows the minimum and maximum input ( $F_{in}$ ) and output ( $F_{pad}$ ) frequency for each possible VCO multiplier mode.

Table 9: Frequency Ranges for Fabric PLL Input Pad (FB\_PLL\_CLKIN), Output Pad (FB\_PLL\_PADOUT) and VCO

| M1 | M0 | VCO Mode                      | FB_PLL_CLKIN<br>(F <sub>in</sub> )<br>Input Frequency Range | FB_PLL_PADOUT<br>(F <sub>VCO</sub> and F <sub>pad</sub> )<br>Pad Output Frequency Range |
|----|----|-------------------------------|-------------------------------------------------------------|-----------------------------------------------------------------------------------------|
| 0  | 0  | 2x                            | 50.0 to 150.0 MHz                                           | 100 to 300 MHz                                                                          |
| 0  | 1  | 4x                            | 25.0 to 75.0 MHz                                            | 100 to 300 MHz                                                                          |
| 1  | 0  | 8x                            | 12.5 to 37.5 MHz                                            | 100 to 300 MHz                                                                          |
| 1  | 1  | Reserved – should not be used |                                                             |                                                                                         |

In addition to the Fabric PLL output pin, the PLL can also drive two clock networks in the Fabric. These two additional outputs, PLLCLK\_OUT and PLLCLK\_OUT2 offer further control over frequency and phase by adding an output frequency divider and phase adjustment control. PLLCLK\_OUT and PLLCLK\_OUT2 can be configured for different output phases, but they both operate at the same frequency. **Table 10** shows the Fabric clock network PLLCLK\_OUT resultant output frequency (F<sub>fab</sub>), duty cycle and phase based on the FD2, FD1, FD0, PS3 and PS2 inputs.

Table 10: Frequency, Duty Cycle and Phase Values for Fabric PLL Output PLLCLK\_OUT

| Fabric Output PLLCLK_OUT |     |     |                               |            |     |     |       |
|--------------------------|-----|-----|-------------------------------|------------|-----|-----|-------|
| FD2                      | FD1 | FD0 | (F <sub>fab</sub> ) Frequency | Duty Cycle | PS3 | PS2 | Phase |
| 0                        | 0   | 0   | F <sub>VCO</sub>              | 50%        | X   | X   | 0°    |
| 0                        | 0   | 1   | F <sub>VCO</sub> / 2          | 50%        | 0   | 0   | 180°  |
|                          |     |     |                               |            | 0   | 1   | 270°  |
|                          |     |     |                               |            | 1   | 0   | 0°    |
|                          |     |     |                               |            | 1   | 1   | 90°   |
| 0                        | 1   | 0   | F <sub>VCO</sub> / 3          | 33%        | X   | X   | 0°    |
| 0                        | 1   | 1   | F <sub>VCO</sub> / 4          | 50%        | 0   | 0   | 0°    |
|                          |     |     |                               |            | 0   | 1   | 90°   |
|                          |     |     |                               |            | 1   | 0   | 180°  |
|                          |     |     |                               |            | 1   | 1   | 270°  |
| 1                        | X   | X   | F <sub>VCO</sub> / 8          | 50%        | 0   | 0   | 270°  |
|                          |     |     |                               |            | 0   | 1   | 0°    |
|                          |     |     |                               |            | 1   | 0   | 90°   |
|                          |     |     |                               |            | 1   | 1   | 180°  |

**NOTE:** PLLCLK\_OUT phase shown in the **Table 10** is based on the period 1/F<sub>fab</sub>.

**NOTE:** An output phase of 0° indicates that the rising edge of PLLCLK\_OUT will be aligned with the rising edge of FB\_PLL\_CLKIN.

**NOTE:** To maintain the phase values shown in **Table 10**, F<sub>VCO</sub> should not exceed 200 MHz. If F<sub>VCO</sub> is set above 200 MHz, the phase of PLLCLK\_OUT will have no guaranteed relation to FB\_PLL\_CLKIN.

**Table 11** shows the Fabric clock network PLLCLK\_OUT2 resultant output frequency ( $F_{fab}$ ), duty cycle and phase based on the FD2, FD1, FD0, PS1 and PS0 inputs.

Table 11: Frequency, Duty Cycle and Phase Values for Fabric PLL Output PLLCLK\_OUT2

| Fabric Output PLLCLK_OUT2 |     |     |                         |            |     |     |       |
|---------------------------|-----|-----|-------------------------|------------|-----|-----|-------|
| FD2                       | FD1 | FD0 | ( $F_{fab}$ ) Frequency | Duty Cycle | PS1 | PS0 | Phase |
| 0                         | 0   | 0   | $F_{VCO}$               | 50%        | X   | X   | 0°    |
| 0                         | 0   | 1   | $F_{VCO} / 2$           | 50%        | 0   | 0   | 180°  |
|                           |     |     |                         |            | 0   | 1   | 270°  |
|                           |     |     |                         |            | 1   | 0   | 0°    |
|                           |     |     |                         |            | 1   | 1   | 90°   |
| 0                         | 1   | 0   | $F_{VCO} / 3$           | 33%        | X   | X   | 0°    |
| 0                         | 1   | 1   | $F_{VCO} / 4$           | 50%        | 0   | 0   | 0°    |
|                           |     |     |                         |            | 0   | 1   | 90°   |
|                           |     |     |                         |            | 1   | 0   | 180°  |
|                           |     |     |                         |            | 1   | 1   | 270°  |
| 1                         | X   | X   | $F_{VCO} / 8$           | 50%        | 0   | 0   | 270°  |
|                           |     |     |                         |            | 0   | 1   | 0°    |
|                           |     |     |                         |            | 1   | 0   | 90°   |
|                           |     |     |                         |            | 1   | 1   | 180°  |

**NOTE:** PLLCLK\_OUT2 phase shown in the **Table 11** is based on the period  $1/F_{fab}$ .

**NOTE:** An output phase of 0° indicates that the rising edge of PLLCLK\_OUT2 will be aligned with the rising edge of FB\_PLL\_CLKIN.

**NOTE:** To maintain the phase values shown in **Table 11**,  $F_{VCO}$  should not exceed 200 MHz. If  $F_{VCO}$  is set above 200 MHz, the phase of PLLCLK\_OUT2 will have no guaranteed relation to FB\_PLL\_CLKIN.

## Fabric PLL Signals

**Table 12** summarizes the key signals of the QL903M Fabric PLL.

Table 12: Fabric PLL I/O Signals

| Signal Name    | I/O | Description                                                                                                                                                                                                                                                                                                                  |
|----------------|-----|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FB_PLL_CLKIN   | I   | <b>Input clock signal.</b> See <b>Table 50</b> for more details.                                                                                                                                                                                                                                                             |
| FB_PLL_RESET_n | I   | <b>Active low reset.</b> See <b>Table 50</b> for more details.                                                                                                                                                                                                                                                               |
| FB_PLL_PADOUT  | O   | <b>PLL output off chip.</b> See <b>Table 50</b> for more details.                                                                                                                                                                                                                                                            |
| PLLCLK_OUT     | O   | <b>PLL output to Fabric (1 of 2).</b> This is the PLL output clock driven to the Fabric clock network. This output runs at the $F_{fab}$ frequency described in <b>Table 10</b> . Furthermore, this output is also phase adjustable. The output frequency and phase is determined by the M(1:0), FD(2:0) and PS(3:2) inputs. |
| PLLCLK_OUT2    | O   | <b>PLL output to Fabric (2 of 2).</b> This is the PLL output clock driven to the Fabric clock network. This output runs at the $F_{fab}$ frequency described in <b>Table 11</b> . Furthermore, this output is also phase adjustable. The output frequency and phase is determined by the M(1:0), FD(2:0) and PS(1:0) inputs. |

Table 12: Fabric PLL I/O Signals (Continued)

| Signal Name | I/O | Description                                                                                                                                                                 |
|-------------|-----|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOCK_DETECT | O   | <b>Active high lock detection signal.</b> This signal is output to the Fabric and goes high when the PLL VCO is locked to the input clock reference.                        |
| M(1:0)      | I   | <b>VCO frequency multiplier input.</b> These inputs are statically driven high or low by the Fabric. See <a href="#">Table 9</a> for their effect on PLL operation.         |
| FD(2:0)     | I   | <b>Fabric output frequency divide input.</b> These inputs are statically driven high or low by the Fabric. See <a href="#">Table 10</a> for their effect on PLL operation.  |
| PS(3:2)     | I   | <b>Phase select input for Fabric output.</b> These inputs are statically driven high or low by the Fabric. See <a href="#">Table 10</a> for their effect on PLL operation.  |
| PS(1:0)     | I   | <b>Phase select input for Fabric output2.</b> These inputs are statically driven high or low by the Fabric. See <a href="#">Table 11</a> for their effect on PLL operation. |

**NOTE:** Because FB\_PLL\_CLKIN, FB\_PLL\_RESET\_n, and FB\_PLL\_PADOUT have appropriate INPAD and OUTPADs included, you do not have to add these pads to your design.

## Advanced Clock Networks

The QL903M device has a large number of extremely advanced and highly flexible clock networks. These consist of three basic types of networks; a Global Network and a Dedicated Network (for low-skew applications), and an I/O Control/Hi-Drive Network (for high-fanout, multi-load applications).

### Global and Dedicated Low-Skew Networks

The Global and Dedicated Networks are low-skew networks typically used to drive clock signals throughout the entire device. In addition, the Global Network can also be used to globally drive other high-fanout signals with low skew (e.g., flip-flop set or reset signals). Both networks are segmented, separated on a per-quadrant basis. (Unlike the QuickLogic Eclipse architecture, the QL903M has only two quadrants.) [Figure 15](#) shows a simplified view of the low-skew clock network architecture in the QL903M device.

Figure 15: Low Skew Clock Architecture

**Table 13** shows the number of Global and Dedicated Networks available per quadrant in the QL903M.

Table 13: Number of QL903M Low-Skew Clock Networks

| Clock Network Type | Quadrant               |                        | Total |
|--------------------|------------------------|------------------------|-------|
|                    | Upper Left             | Upper Right            |       |
| Global             | 8<br>(5 are Quad-Nets) | 8<br>(5 are Quad-Nets) | 16    |
| Dedicated          | 1                      | 1                      | 2     |
| Total              | 9                      | 9                      | 18    |

As **Table 13** shows, there are a total of nine low-skew networks per quadrant in the QL903M, making a total of eighteen in the entire device. Each quadrant contains eight Global Networks and one Dedicated Network.

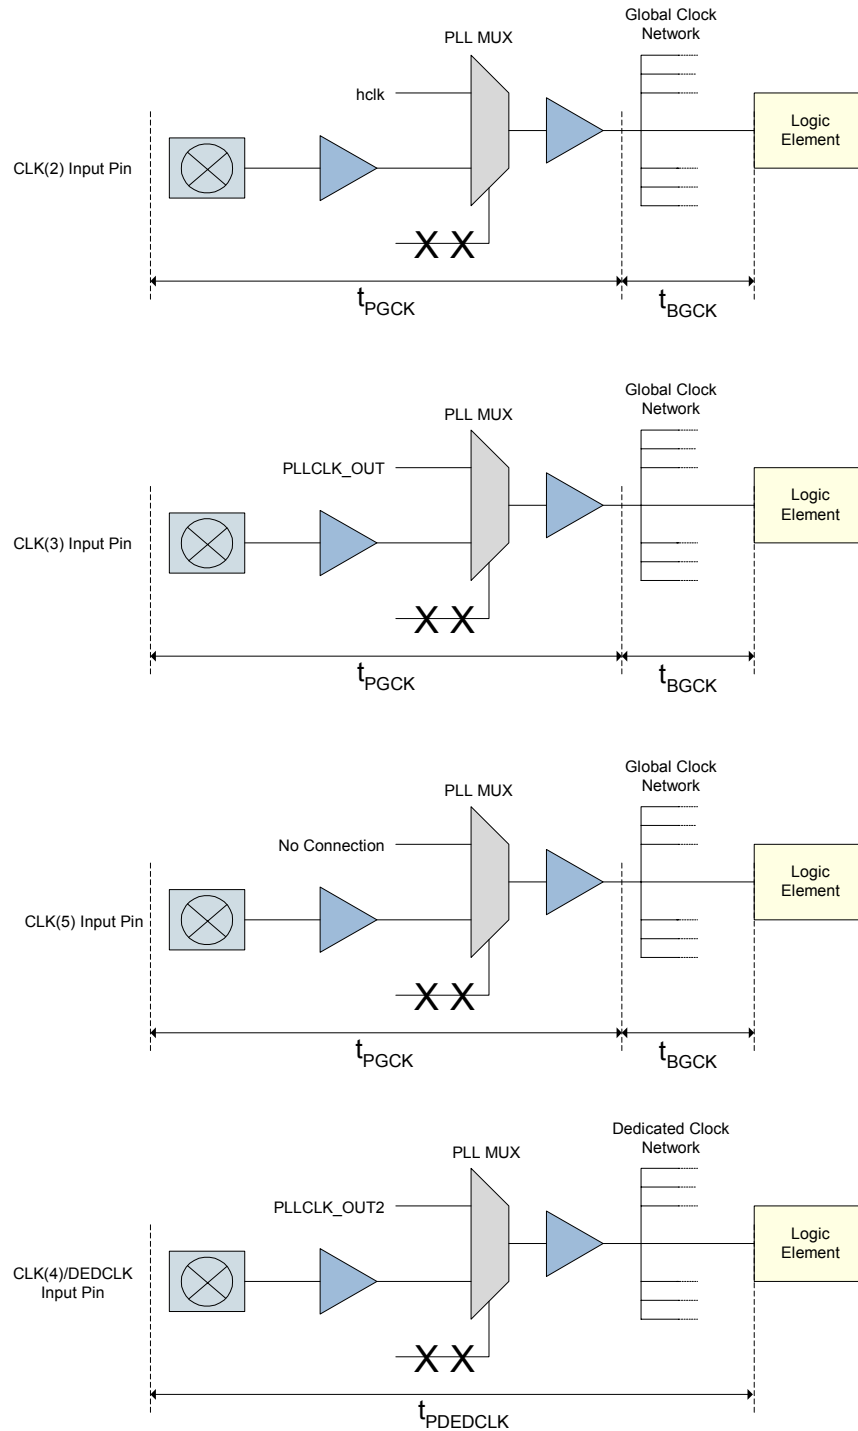

The Global Network and Dedicated Network differ slightly in performance and flexibility. The Dedicated Network offers superb low-skew and minimal pin to logic element delay performance, but can only drive the clock inputs of specific Fabric elements. The Global Network offers more flexibility to drive a variety of inputs in the Fabric as well as internal ASSP port inputs, but at a slight increase in skew and delay. **Table 14** outlines all allowable input destinations for each clock network type.

Table 14: Allowable Inputs Destinations for Global and Dedicated Networks

| Element        | Inputs That Can be Driven by the Global Clock Network | Inputs That Can be Driven by the Dedicated Clock Network |
|----------------|-------------------------------------------------------|----------------------------------------------------------|
| Logic Cells    | QC                                                    | QC                                                       |
|                | A2                                                    |                                                          |
|                | F1                                                    |                                                          |
|                | QS                                                    |                                                          |
|                | QR                                                    |                                                          |
| RAM Modules    | WCLK                                                  | WCLK                                                     |
|                | RCLK                                                  |                                                          |
|                | RE                                                    | RCLK                                                     |
|                | WE                                                    |                                                          |
| ECUs           | CLK                                                   | -                                                        |
|                | RESET                                                 |                                                          |
| I/O Cells      | IQC                                                   | IQC                                                      |
|                | IQR                                                   |                                                          |
|                | EQE                                                   |                                                          |
|                | IQE                                                   |                                                          |
|                | IE                                                    |                                                          |
| ASSP Interface | All Inputs                                            | -                                                        |

Each quadrant consists of an element called the PLLMUX that drives the Global Networks and the Dedicated Network in the quadrant. The PLLMUX selects between external CLK input pins and clock signals that are driven from other elements internal to the device such as the Fabric PLL and the ASSP System Bus clock (hclk). **Figure 16** shows a simplified schematic diagram of the CLK input pins, the PLLMUX elements and the associated clock networks.

Figure 16: Low Skew Clock Structure Schematic Based Upon PLLMUX Elements (1 of 2 Quadrants)

If either of the Fabric PLL outputs or hclk are utilized in a given quadrant of the Fabric design, the QuickWorks software automatically configures the corresponding PLLMUX to select the internal clock input. Each quadrant consists of four PLLMUX elements of which one input is tied to a specific CLK input pin as shown in **Table 15**.

Table 15: PLLMUX Input Signals and Output Type (Per Quadrant)

| Input         |                  | Output Type             |
|---------------|------------------|-------------------------|
| Pin           | Internal Signals |                         |
| CLK(2)        | hclk             | Global clock network    |
| CLK(3)        | PLLCLK_OUT       | Global clock network    |
| CLK(4)/DEDCLK | PLLCLK_OUT2      | Dedicated clock network |
| CLK(5)        | -                | Global clock network    |

As **Table 15** indicates, once a PLLMUX is used to drive an internal signal onto the Global or Dedicated Networks, the corresponding CLK input pin is blocked from entering that quadrant.

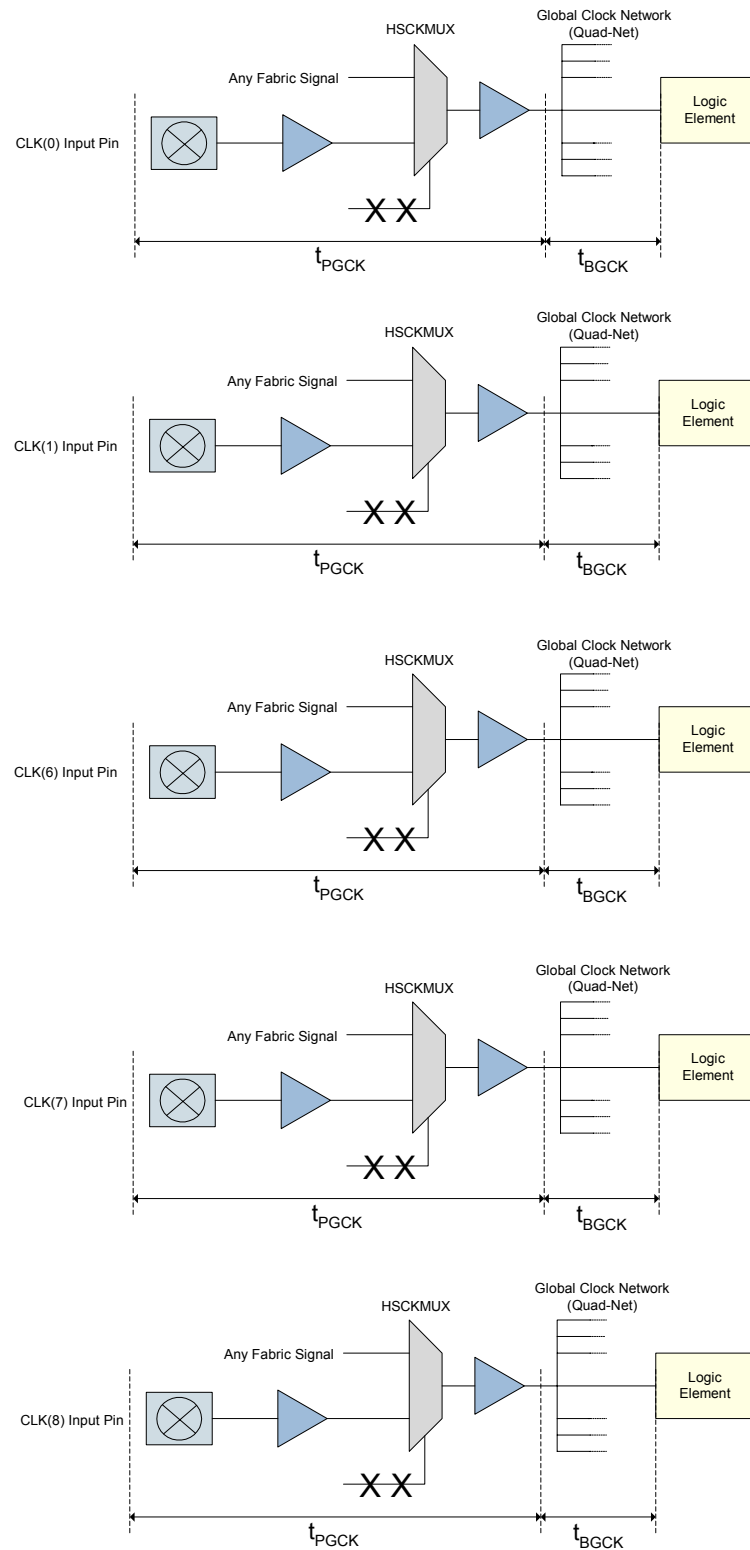

**NOTE:** If either of the Fabric PLL outputs or hclk are utilized in the Fabric design, and external clock pins are also utilized, the designer should choose clock input pins on the device that do not conflict with these corresponding PLLMUX elements.

#### Quad-Net Network (Subset of the Global Network)

In each quadrant, the remaining five Global Networks are also referred to as Quad-Net Networks. Quad-Nets are networks that can be driven by input CLK pins or by signals that are generated internally to the Fabric. Quad-Nets are driven by an element in the Fabric called the HSCKMUX. **Figure 17** shows a simplified schematic diagram of the CLK input pins, the HSCKMUX elements and the associated Quad-Net networks.

Figure 17: Low Skew Clock Structure Schematic Based Upon HSKMUX Elements (1 of 2 Quadrants)

By instantiating the gclkbuff\_25um macro with a given Fabric signal as its input, the designer can program an HSCKMUX to drive this signal on a Quad-Net (the QuickWorks tool automatically chooses which HSCKMUX to use). Each quadrant consists of five HSCKMUX elements of which one input is tied to a specific CLK input pin as shown in **Table 16**.

Table 16: HSCKMUX Input Signals and Output Type (Per Quadrant)

| Input  |                  | Output Type                     |
|--------|------------------|---------------------------------|
| Pin    | Internal Signals |                                 |
| CLK(0) | Any Signal       | Global clock network (Quad-Net) |
| CLK(1) | Any Signal       | Global clock network (Quad-Net) |
| CLK(6) | Any Signal       | Global clock network (Quad-Net) |
| CLK(7) | Any Signal       | Global clock network (Quad-Net) |
| CLK(8) | Any Signal       | Global clock network (Quad-Net) |

As **Table 16** indicates, once an HSCKMUX is used to drive an internal signal onto the Quad-Net Network, the corresponding CLK input pin is blocked from entering that quadrant.

**NOTE:** If the sum of utilized clock input pins from **Table 16** and the number of instantiated gclkbuff\_25um macros is greater than five, the QuickWorks software may be unable to successfully resolve the conflicts between the CLK input pins and the internally generated clock input signals. This is dependant on several factors, but in most cases can be attributed to the size and complexity of the Fabric design.

### I/O Control/Hi-Drive Network

The I/O Control/Hi-Drive Network is used primarily to drive high-fanout (typically other than clock or reset) signals throughout the device. Each bank of I/Os has two input-only pins entitled IOCTRL that can be programmed to drive the IQC (flip-flop clock), IQR (flip-flop reset), EQE & IQE (flip-flop enables), and IE (output enable) inputs of each I/O cell in that bank. These input-only pins also simultaneously serve as high drive inputs to any logic element input located in the adjacent quadrant. In addition, the I/O Control/Hi-Drive Network can be driven by the internal logic by instantiating the io\_buff\_25um macro. The QL903M has a total of eight IOCTRL input pins which are also shared with the io\_buff\_25um macros (i.e., if a io\_buff\_25um macro is utilized at a specific location, the corresponding IOCTRL input pin is ignored by the device. The performance of this network is presented in **Table 35**.

### General Routing Network

QL903M devices are delivered with six types of routing resources as follows: short (sometimes called segmented) wires, dual wires, quad wires, express wires, distributed networks, and default wires. Short wires span the length of one logic cell, always in the vertical direction. Dual wires run horizontally and span the length of two logic cells. Short and dual wires are predominantly used for local connections. Default wires supply V<sub>CC</sub> and GND (Logic '1' and Logic '0') to each column of logic cells.

Quad wires have passive link interconnect elements every fourth logic cell. As a result, these wires are typically used to implement intermediate length or medium fan-out nets.

Express lines run the length of the programmable logic uninterrupted. Each of these lines has a higher capacitance than a quad, dual, or short wire, but less capacitance than shorter wires connected to run the length of the device. The resistance will also be lower because the express wires don't require the use of "pass" links. Express wires provide higher performance for long routes or high fan-out nets.

Distributed networks are described in **Advanced Clock Networks** on page 29. These wires span the programmable logic and are driven by “column clock” buffers. All clock network pin buffers (both Dedicated and Global) are hard wired to individual sets of column clock buffers.

## Programmable I/O

The QL903M features a variety of distinct I/O pins to maximize performance, functionality, and flexibility with bi-directional I/O pins and input-only pins. All input and I/O pins are 1.8 V, 2.5 V, and 3.3 V tolerant and comply with the specific I/O standard selected. For single-ended I/O standards, VCCIO(A:D) specifies the input tolerance and the output drive. For example, the VCCIO(A:D) pins must be tied to a 3.3 V supply to provide 3.3 V compliance. For voltage referenced I/O standards (e.g. SSTL), the voltage supplied to the INREF(A:D) pins in each bank specifies the input switch point. The QL903M can also support the LVDS and LVPECL I/O standards with the use of external resistors (see **Table 17**).

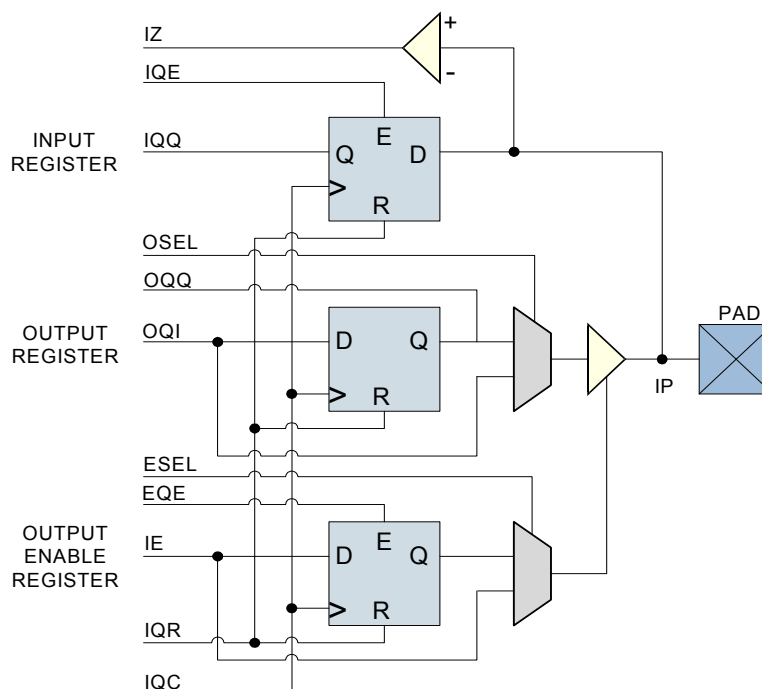

Table 17: I/O Standards and Applications

| I/O Standard | Reference Voltage | Output Voltage | Application          |
|--------------|-------------------|----------------|----------------------|
| LVTTTL       | n/a               | 3.3 V          | General Purpose      |
| LVC MOS25    | n/a               | 2.5 V          | General Purpose      |
| LVC MOS18    | n/a               | 1.8 V          | General Purpose      |
| PCI          | n/a               | 3.3 V          | PCI Bus Applications |
| GTL+         | 1                 | n/a            | Backplane            |
| SSTL3        | 1.5               | 3.3 V          | SDRAM                |
| SSTL2        | 1.25              | 2.5 V          | SDRAM                |

As designs become more complex and requirements more stringent, several application-specific I/O standards have emerged for specific applications. I/O standards for processors, memories, and a variety of bus applications have become commonplace and a requirement for many systems. In addition, I/O timing has become a greater issue with specific requirements for setup, hold, clock to out, and switching times. The QL903M has addressed these new system requirements and includes a new I/O cell which consists of programmable I/Os as well as a new cell structure consisting of three registers—Input, Output, and OE.

The bi-directional I/O pin options can be programmed for input, output, or bi-directional operation. As shown in **Figure 18**, each bi-directional I/O pin is associated with an I/O cell which features an input register, an input buffer, an output register, a three-state output buffer, an output enable register, and 2 two-to-one output multiplexers. The select lines of the two-to-one multiplexers are static and must be connected to either  $V_{cc}$  or GND.

Figure 18: QL903M I/O Cell

For input functions, I/O pins can provide combinatorial, registered data, or both options simultaneously to the logic array. For combinatorial input operation, data is routed from I/O pins through the input buffer to the array logic. For registered input operation, I/O pins drive the D input of the input registers, allowing data to be captured with fast set-up times without consuming internal logic cell resources. The comparator and multiplexer in the input path allows for native support of I/O standards with reference points offset from traditional ground.

For output functions, I/O pins can receive combinatorial or registered data from the logic array. For combinatorial output operation, data is routed from the logic array through a multiplexer to the I/O pin. For registered output operation, the array logic drives the D input of the output register which in turn drives the I/O pin through a multiplexer. The multiplexer allows either a combinatorial or a registered signal to be driven to the I/O pin. Using the output register will also decrease the  $T_{co}$ . Since the output register does not need to drive the routing the length of the output path is also reduced.

The three-state output buffer controls the flow of data from the array logic to the I/O pin and allows the I/O pin to act as an input and/or output. The buffer's output enable can be individually controlled by the logic cell array or any pin (through the regular routing resources), or it can be bank-controlled through one of the global networks. The signal can also be either combinatorial or registered. This is identical to that of the flow for the output register. For combinatorial control operation data is routed from the logic array through a multiplexer to the three-state control. The IOCTRL pins can directly drive the OE and CLK signals for all I/O cells within the same bank.

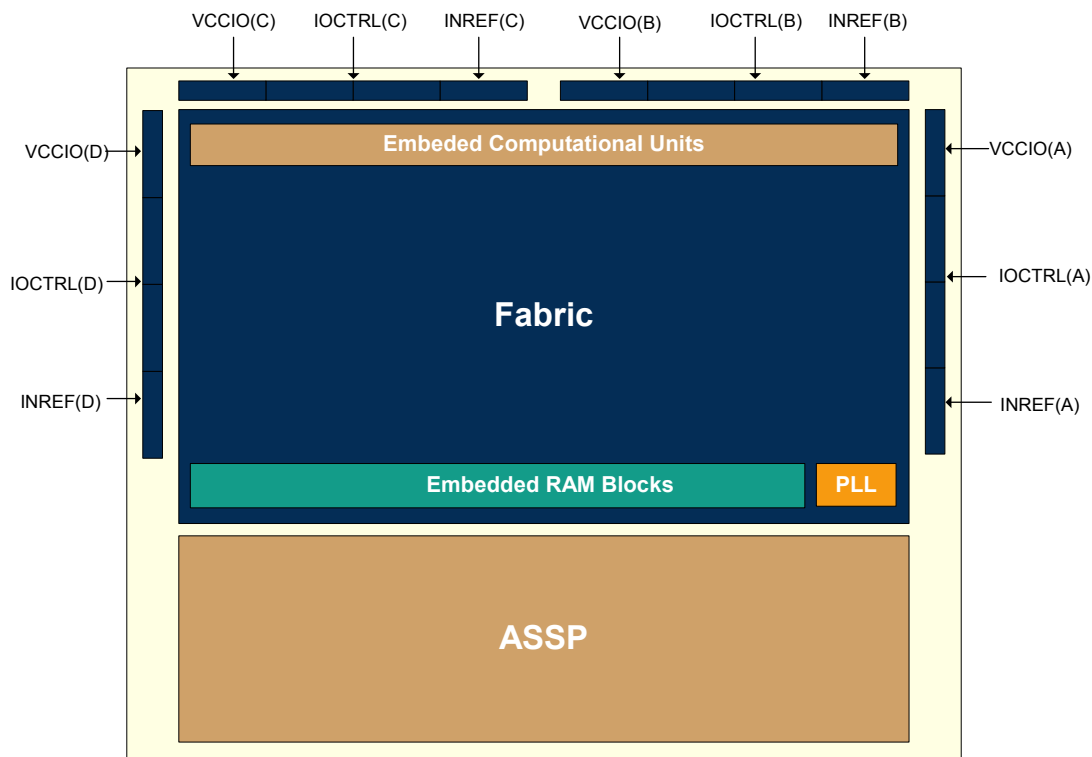

For registered control operation, the array logic drives the D input of the OE register which in turn drives the three-state control through a multiplexer. The multiplexer allows either a combinatorial or a registered signal to be driven to the three-state control.

When I/O pins are unused, the OE controls can be permanently disabled, allowing the output register to be used for registered feedback into the logic array.

I/O cell registers are controlled by clock, clock enable, and reset signals, which can come from the regular routing resources, from one of the global networks, or from two IOCTRL input pins per bank of I/Os. The CLK and RESET signals share common lines, while the clock enables for each register can be independently controlled. I/O interface support is programmable on a per bank basis. The QL903M contains four I/O banks. **Figure 19** illustrates the I/O bank configurations.

Each I/O bank is independent of other I/O banks and each I/O bank has its own VCCIO and INREF supply inputs. A mixture of different I/O standards can be used on the device; however, there is a limitation as to which I/O standards can be supported within a given bank. Only standards that share a common VCCIO and INREF can be shared within the same bank (e.g., PCI and LVTTTL).

Figure 19: Multiple I/O Banks

### Programmable Slew Rate

Each I/O has programmable slew rate capability—the slew rate can be either fast or slow. The slower rate can be used to reduce the switching noise of each I/O. See **Table 41** through **Table 43** for specific information on the slew rates for the Fabric I/O pins. The option to change the slew rate is selectable through QuickWorks in the Tools/Configure Pins window in SpDE.

### Programmable Weak Pull-Down

A programmable Weak Pull-Down resistor is available on each I/O. The I/O Weak Pull-Down eliminates the need for external pull down resistors for used I/Os. The spec for pull-down current is maximum of 150  $\mu$ A under worst case conditions. The option to use the programmable weak pull-down resistor is selectable through QuickWorks in the Tools/Configure Pins window in SpDE.

Figure 20: Programmable I/O Weak Pull-Down

### Global Power-On Reset (POR)

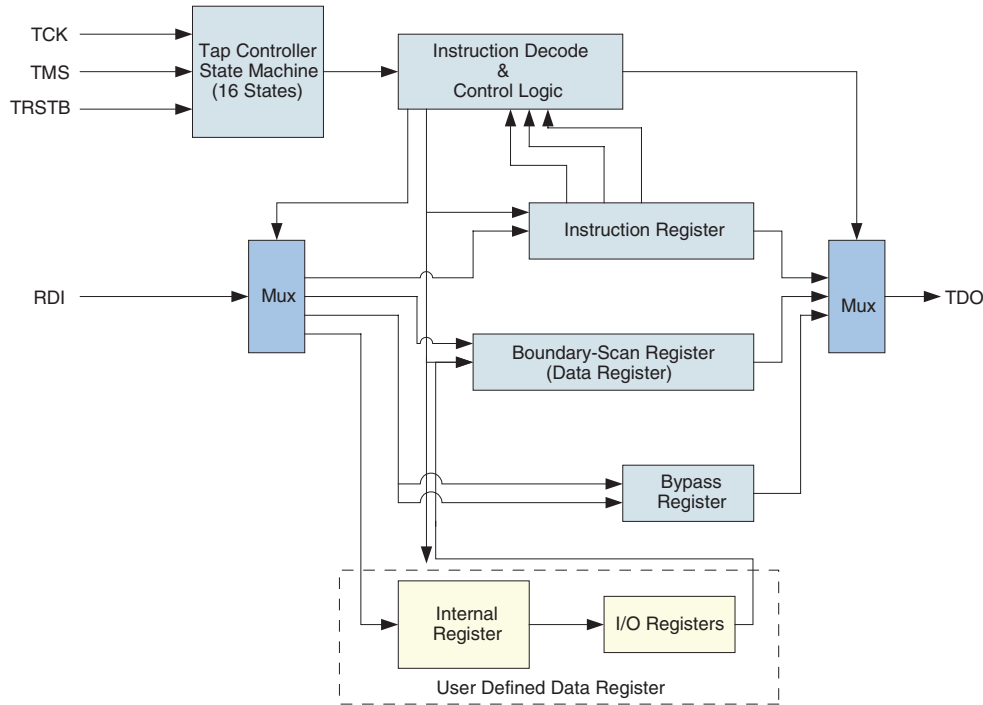

The QL903M family of devices features a global power-on reset. This reset is hardwired to all registers and resets them to Logic '0' upon power-up of the device. In QuickLogic devices, the asynchronous Reset input to flip-flops has priority over the Set input; therefore, the Global POR will reset all flip-flops during power-up. If you want to set the flip-flops to Logic '1', you must assert the "Set" signal after the Global POR signal has been deasserted. This is accomplished by holding the "Set" signal high for at least 1 ms after the  $V_{CC}$  supply has reached 1.95 V.

Figure 21: Power-On Reset

## Joint Test Access Group (JTAG)

Figure 22: JTAG Block Diagram

Microprocessors and Application Specific Integrated Circuits (ASICs) pose many design challenges, one problem being the accessibility of test points. JTAG formed in response to this challenge, resulting in IEEE standard 1149.1, the Standard Test Access Port and Boundary Scan Architecture.

The JTAG boundary scan test methodology allows complete observation and control of the boundary pins of a JTAG-compatible device through JTAG software. A Test Access Port (TAP) Controller works in concert with the Instruction Register (IR), which allow users to run three required tests along with several user-defined tests.

JTAG tests allow users to reduce system debug time, reuse test platforms and tools, and reuse subsystem tests for fuller verification of higher level system elements.

The 1149.1 standard requires the following three tests:

- **Extest Instruction.** The Extest instruction performs a PCB interconnect test. This test places a device into an external boundary test mode, selecting the boundary scan register to be connected between the TAPs Test Data In (TDI) and Test Data Out (TDO) pins. Boundary scan cells are preloaded with test patterns (through the Sample/Preload Instruction), and input boundary cells capture the input data for analysis.
- **Sample/Preload Instruction.** This instruction allows a device to remain in its functional mode, while selecting the boundary scan register to be connected between the TDI and TDO pins. For this test, the boundary scan register can be accessed through a data scan operation, allowing users to sample the functional data entering and leaving the device.

- **Bypass Instruction.** The Bypass instruction allows data to skip a device's boundary scan entirely, so the data passes through the bypass register. The Bypass instruction allows users to test a device without passing through other devices. The bypass register is connected between the TDI and TDO pins, allowing serial data to be transferred through a device without affecting the operation of the device.

### JTAG BSDL Support

- BSDL-Boundary Scan Description Language
- Machine-readable data for test equipment to generate testing vectors and software
- BSDL files available for all device/package combinations from QuickLogic
- Extensive industry support available and ATVG (Automatic Test Vector Generation)

### Security Links

There are several security links: to disable reading logic from the array, and to disable JTAG access to the device. Programming these optional links completely disables access to the device from the outside world and provides an extra level of design security not possible in SRAM-based FPGAs. The option to program these links is selectable through QuickWorks in the Tools/Options/Device Programming window in SpDE.

### Power-Up Loading Link

The flexibility link enables Power-Up Loading of the Embedded RAM blocks. If the link is programmed, the Power Up Loading state machine is activated during power-up of the device. The state machine communicates with an external EPROM via the JTAG pins to download memory contents into the on-chip RAM. If the link is not programmed, Power-Up Loading is not enabled and the JTAG pins function as they normally would. The option to program this link is selectable through QuickWorks in the Tools/Options/Device Programming window in SpDE. For more information on Power-Up Loading, see QuickLogic Application Note 55 at <http://www.quicklogic.com/images/appnote55.pdf>. See the Power-Up Loading power-up sequencing requirement for proper functionality in **Figure 23**.

Figure 33: SDRAM Waveforms

Table 25: SDRAM AC Timing

| Symbol         | Parameter <sup>a</sup>                       | QL903M175 |      | QL903M200 |      | Units |
|----------------|----------------------------------------------|-----------|------|-----------|------|-------|
|                |                                              | Min.      | Max. | Min.      | Max. |       |
| $T_{CO}$       | Clock to out, all control and data signals   | 1.8       | 7.1  | 1.6       | 6.2  | ns    |
| $T_{SU}$       | Setup time, read data                        | 1.1       | -    | 0.95      | -    | ns    |
| $T_H$          | Hold time, read data                         | 0.22      | -    | 0.19      | -    | ns    |
| $T_{PD-SDCLK}$ | Maximum allowed delay, SD_CLKOUT to SD_CLKIN | -         | 2.81 | -         | 2.45 | ns    |

a. All timing is measured with respect to the rising edge of SD\_CLKIN. All measurements are based on I/Os with 35 pF load except for SD\_CLKOUT, which has a load of 15 pF.

## I/O Peripheral Controller

Figure 34: SRAM Read Waveforms

Table 26: SRAM AC Read Timing Requirements

| Symbol | Parameter                                                                 | QL903M175 |      | QL903M200 |      | Units |
|--------|---------------------------------------------------------------------------|-----------|------|-----------|------|-------|
|        |                                                                           | Min.      | Max. | Min.      | Max. |       |
| D0     | Access time, address and byte lane output to read data valid <sup>a</sup> | -         | 8.3  | -         | 7.3  | ns    |
| D1     | Access time, output enable to read data valid                             | -         | 13.9 | -         | 12.1 | ns    |

a. Measurement is based on SD\_CLKIN feedback with 0 ns delay and SD\_CLKOUT load of 15 pF. Allowed access time will be decreased by SD\_CLKIN to SD\_CLKOUT delay.

Figure 35: SRAM Write Waveforms

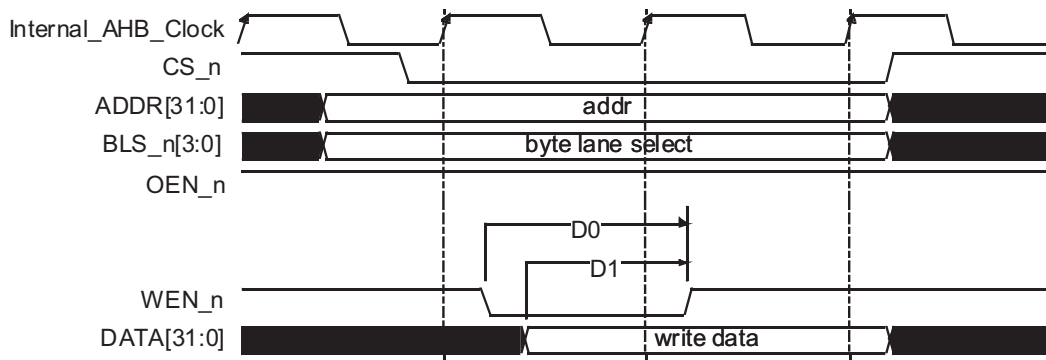

Table 27: SRAM AC Write Timing Characteristics

| Symbol | Parameter                                                               | QL903M175 |      | QL903M200 |      | Units       |
|--------|-------------------------------------------------------------------------|-----------|------|-----------|------|-------------|
|        |                                                                         | Min.      | Max. | Min.      | Max. |             |
| D0     | Write enable low pulse width                                            | 1         | -    | 1         | -    | hclk period |
| D1     | Write output data valid before rising edge of write enable <sup>a</sup> | 4.7       | -    | 4.1       | -    | ns          |

a. Measurement is based on SD\_CLKIN feedback with 0 ns delay and SD\_CLKOUT load of 15 pF. Setup time will be decreased by SD\_CLKIN to SD\_CLKOUT delay.

## PCI Controller

Figure 36: PCI Waveforms

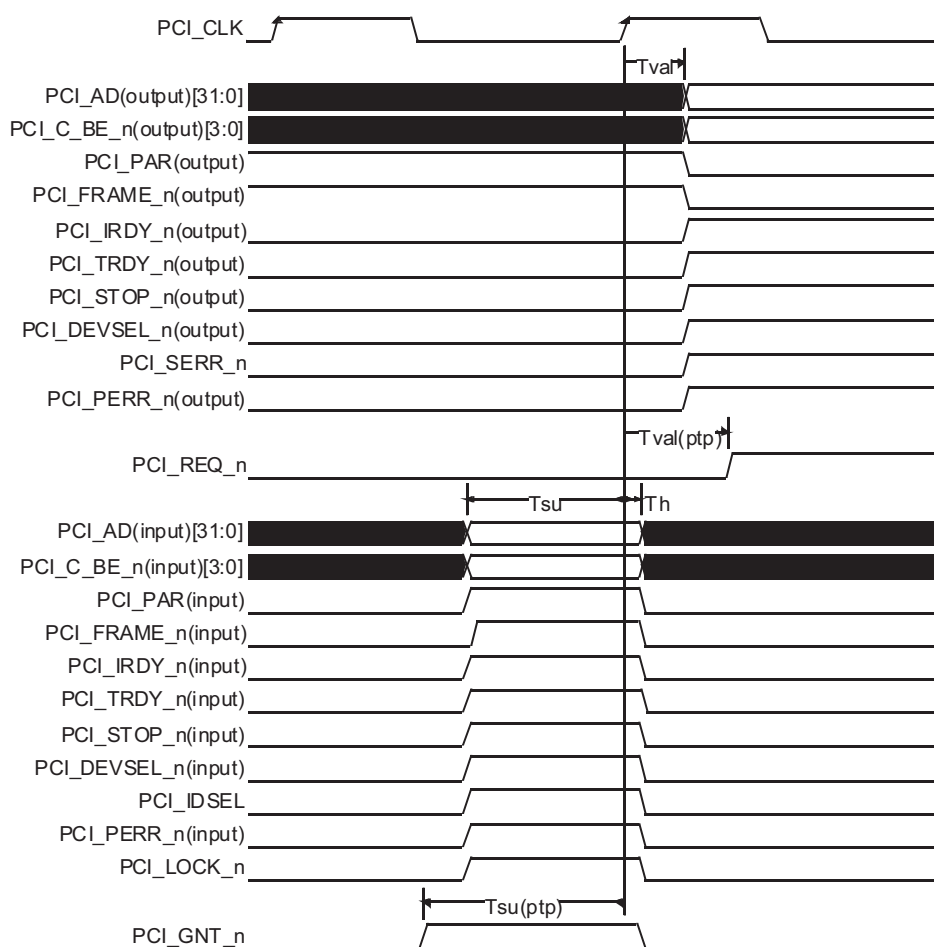

Table 28: PCI AC Timing

| Parameter <sup>a</sup>            |                                                                   | 66 MHz |      | 33 MHz |      | Units  |
|-----------------------------------|-------------------------------------------------------------------|--------|------|--------|------|--------|
|                                   |                                                                   | Min.   | Max. | Min.   | Max. |        |
| t <sub>CYC</sub>                  | PCI_CLK Cycle Time                                                | 15     | -    | 30     | -    | ns     |
| t <sub>HIGH</sub>                 | PCI_CLK High Time                                                 | 6      | -    | 11     | -    | ns     |
| t <sub>LOW</sub>                  | PCI_CLK Low Time                                                  | 6      | -    | 11     | -    | ns     |
| –                                 | PCI_CLK Slew Rate                                                 | 1.5    | 4    | 1      | 4    | V/ns   |
| t <sub>VAL</sub>                  | PCI_CLK to Signal Valid Delay                                     | 2      | 6    | 2      | 11   | ns     |
| t <sub>VAL</sub> (PTP)            | PCI_CLK to Signal Valid Delay point-to-point signals <sup>b</sup> | 2      | 6    | 2      | 12   | ns     |
| t <sub>ON</sub>                   | Float to Active Delay                                             | 2      | -    | 2      | -    | ns     |
| t <sub>OFF</sub>                  | Active to Float Delay                                             | -      | 14   | -      | 28   | ns     |
| t <sub>SU</sub>                   | Input Setup Time to PCI_CLK based signals                         | 3      | -    | 7      | -    | ns     |
| t <sub>SU</sub> (PTP)             | Input Setup Time to PCI_CLK point-to-point                        | 5      | -    | 10, 12 | -    | ns     |
| t <sub>H</sub>                    | Input Hold Time from PCI_CLK                                      | 0      | -    | 0      | -    | ns     |
| t <sub>RST</sub>                  | Reset Active Time after power stable                              | 1      | -    | 1      | -    | ms     |
| t <sub>RST-CLK</sub>              | Reset Active Time after PCI_CLK stable                            | 100    | -    | 100    | -    | μs     |
| t <sub>RST-OFF</sub> <sup>c</sup> | Reset Active to output float delay                                |        | 40   |        | 40   | ns     |
| t <sub>RHFA</sub>                 | PCI_RST_n high to first configuration access                      | 2      | -    | 2      | -    | clocks |
| t <sub>RHFF</sub>                 | PCI_RST_n high to first PCI_FRAME_n assertion                     | 5      | -    | 5      | -    | clocks |

a. All PCI pins are synchronous to the PCI clock except for PCI\_RST\_n and PCI\_INTA\_n.

b. Point-to-point signals include PCI\_REQ\_n and PCI\_GNT\_n.

c. All output drivers must be 3-stated when PCI\_RST\_n is active.

## System SRAM

Figure 37: System SRAM Block Diagram

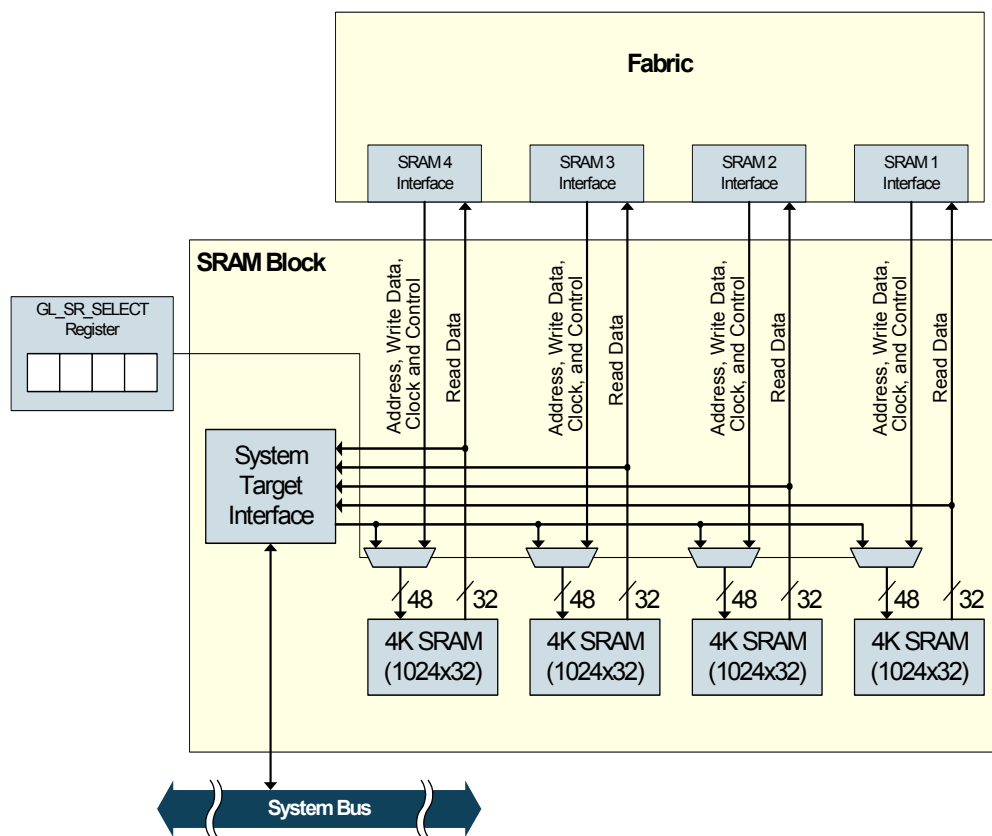

Figure 38: System SRAM Fabric Interface Read Timing (one SRAM interface shown)

Figure 39: System SRAM Fabric Interface Write Timing (one SRAM interface shown)

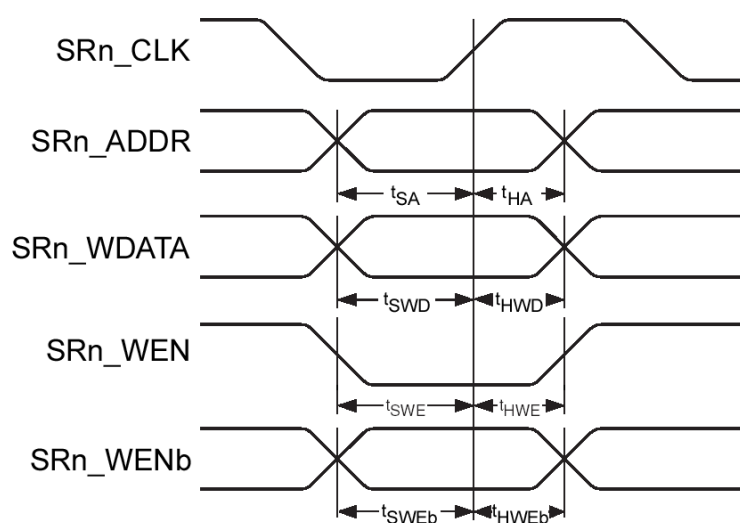

Table 29: System SRAM Fabric Interface Timing

| Symbol     | Parameter                           | QL903M175 |      | QL903M200 |      | Units |
|------------|-------------------------------------|-----------|------|-----------|------|-------|
|            |                                     | Min.      | Max. | Min.      | Max. |       |
| $t_{SA}$   | Setup time, address input           | 1.40      | -    | 1.23      | -    | ns    |
| $t_{HA}$   | Hold time, address input            | 0.48      | -    | 0.42      | -    | ns    |
| $t_{SWD}$  | Setup time, write data input        | 1.81      | -    | 1.59      | -    | ns    |
| $t_{HWD}$  | Hold time, write data input         | 0.56      | -    | 0.49      | -    | ns    |
| $t_{SWE}$  | Setup time, write enable input      | 0.60      | -    | 0.53      | -    | ns    |
| $t_{HWE}$  | Hold time, write enable input       | 0.54      | -    | 0.48      | -    | ns    |
| $t_{SWEb}$ | Setup time, byte write enable input | 1.13      | -    | 0.99      | -    | ns    |
| $t_{HWEb}$ | Hold time, byte write enable input  | 0.94      | -    | 0.82      | -    | ns    |
| $t_{CORD}$ | Clock-to-out time, read data output | -         | 5.17 | -         | 4.52 | ns    |

**NOTE:** For timing values related to each individual ASSP SRAM block, refer to **Table 46** and **Table 47**.

## Logic Cells

Figure 40: QL903M Logic Cell

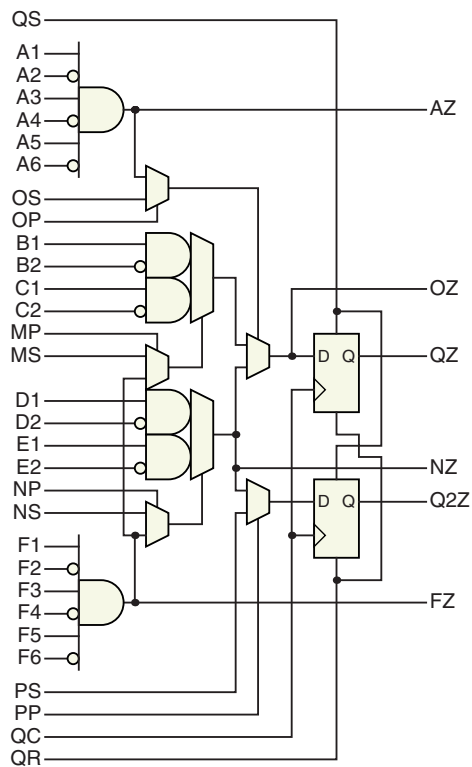

Figure 41: Logic Cell Flip-Flop

Figure 42: Logic Cell Flip-Flop Timings—First Waveform

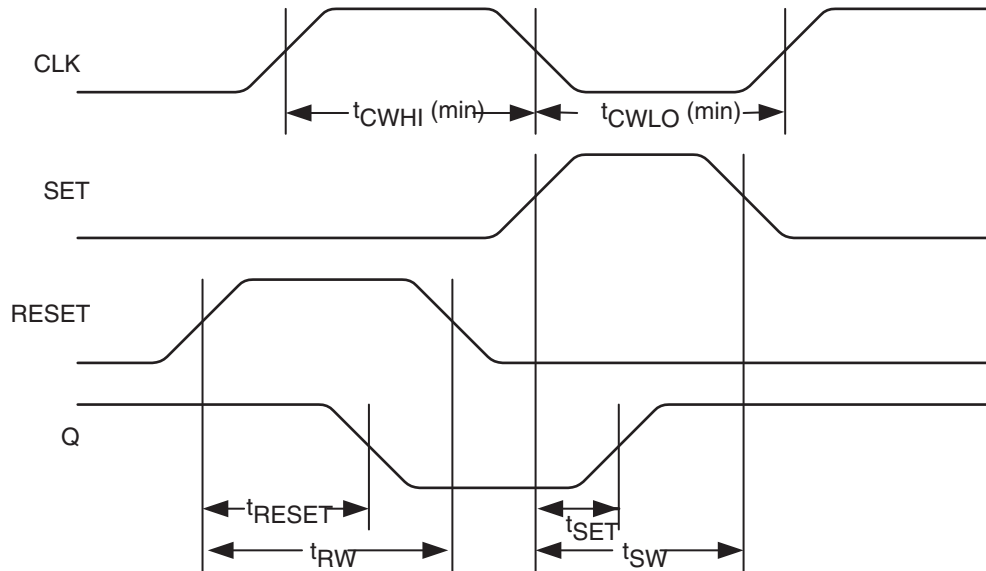

Figure 43: Logic Cell Flip-Flop Timings—Second Waveform

Table 30: Logic Cells

| Symbol      | Parameter                                                                                                       | Value   |         |
|-------------|-----------------------------------------------------------------------------------------------------------------|---------|---------|
|             |                                                                                                                 | Min.    | Max.    |
| $t_{PD}$    | Combinatorial Delay of the longest path: time taken by the combinatorial circuit to output                      | 0.28 ns | 0.95 ns |
| $t_{SU}$    | Setup time: time the synchronous input of the flip-flop must be stable before the active clock edge             | 0.25 ns | -       |
| $t_{HL}$    | Hold time: time the synchronous input of the flip-flop must be stable after the active clock edge               | 0 ns    | -       |
| $t_{CO}$    | Clock-to-out delay: the amount of time taken by the flip-flop to output after the active clock edge.            | 0.22 ns | 0.52 ns |
| $t_{CWHI}$  | Clock High Time: required minimum time the clock stays high                                                     | 0.46 ns | -       |
| $t_{CWLO}$  | Clock Low Time: required minimum time that the clock stays low                                                  | 0.46 ns | -       |
| $t_{SET}$   | Set Delay: time between when the flip-flop is "set" (high) and when the output is consequently "set" (high)     | -       | 0.69 ns |
| $t_{RESET}$ | Reset Delay: time between when the flip-flop is "reset" (low) and when the output is consequently "reset" (low) | -       | 1.09 ns |
| $t_{SW}$    | Set Width: time that the SET signal must remain high/low                                                        | 0.3 ns  | -       |
| $t_{RW}$    | Reset Width: time that the RESET signal must remain high/low                                                    | 0.3 ns  | -       |

## Dual-Port SRAM Modules

Figure 44: RAM Module

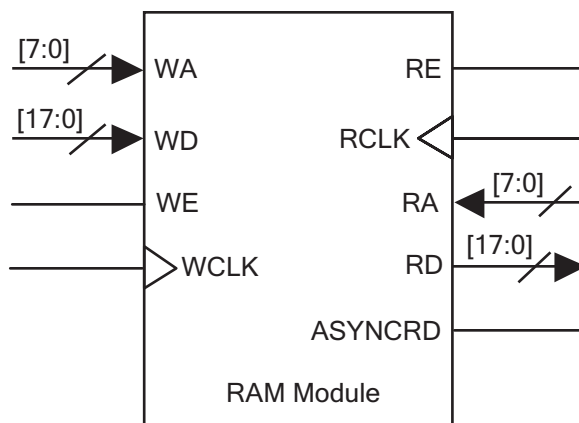

Figure 45: RAM Cell Synchronous Write Timing

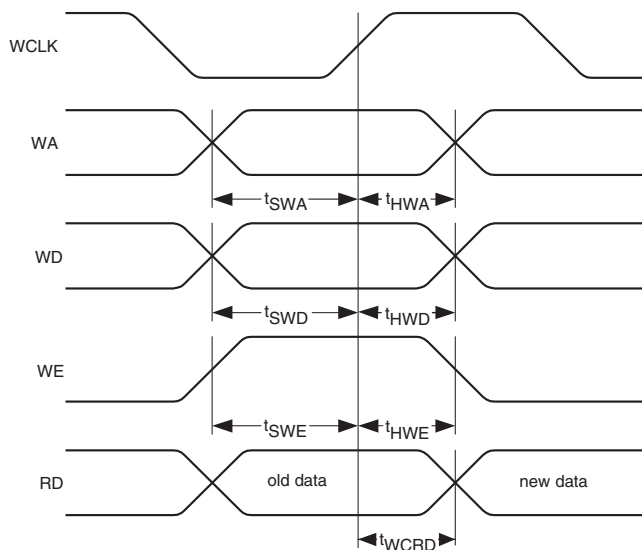

Table 31: RAM Cell Synchronous Write Timing

| Symbol                            | Parameter                                                                                                    | Value    |         |
|-----------------------------------|--------------------------------------------------------------------------------------------------------------|----------|---------|
|                                   |                                                                                                              | Min.     | Max.    |
| RAM Cell Synchronous Write Timing |                                                                                                              |          |         |
| t <sub>SWA</sub>                  | WA setup time to WCLK: time the WRITE ADDRESS must be stable before the active edge of the WRITE CLOCK       | 0.675 ns | -       |
| t <sub>HWA</sub>                  | WA hold time to WCLK: time the WRITE ADDRESS must be stable after the active edge of the WRITE CLOCK         | 0 ns     | -       |
| t <sub>SWD</sub>                  | WD setup time to WCLK: time the WRITE DATA must be stable before the active edge of the WRITE CLOCK          | 0.654 ns | -       |
| t <sub>HWD</sub>                  | WD hold time to WCLK: time the WRITE DATA must be stable after the active edge of the WRITE CLOCK            | 0 ns     | -       |
| t <sub>SWE</sub>                  | WE setup time to WCLK: time the WRITE ENABLE must be stable before the active edge of the WRITE CLOCK        | 0.623 ns | -       |
| t <sub>HWE</sub>                  | WE hold time to WCLK: time the WRITE ENABLE must be stable after the active edge of the WRITE CLOCK          | 0 ns     | -       |
| t <sub>WCRD</sub>                 | WCLK to RD (WA = RA): time between the active WRITE CLOCK edge and the time when the data is available at RD | -        | 4.38 ns |

Figure 46: RAM Cell Synchronous and Asynchronous Read Timing

Table 32: RAM Cell Synchronous and Asynchronous Read Timing

| Symbol                            | Parameter                                                                                            | Value    |         |
|-----------------------------------|------------------------------------------------------------------------------------------------------|----------|---------|

a. t<sub>PD</sub>, t<sub>SU</sub>, and t<sub>CO</sub> do not include routing paths in/out of the ECU block.

b. Internal feedback path in ECU restricts max. clk frequency to 238 MHz.

c. B (15:0) set to zero.

**NOTE:** Timing numbers in **Table 33** represent -2 Worst Case Commercial conditions.

## Fabric PLL

Figure 48: QL903M Fabric PLL Block Diagram

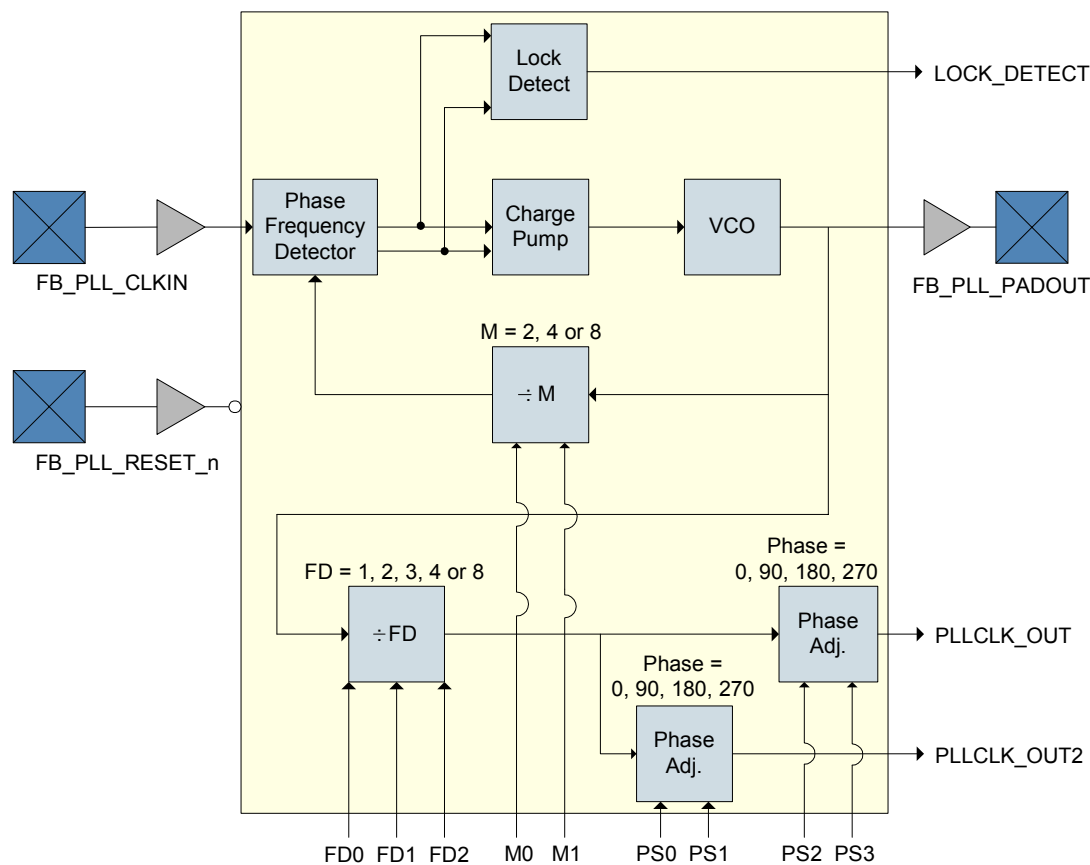

Table 34: Fabric PLL Timing Parameters

| Peak to Peak Jitter | VCO Frequency Range | Minimum Lock Frequency | Duty Cycle | Crystal Accuracy | Lock Time | Propagation Delay<br>FB_PLL_CLKIN to<br>FB_PLL_PADOUT |
|---------------------|---------------------|------------------------|------------|------------------|-----------|-------------------------------------------------------|
| 200 ps              | 100 to 300 MHz      | 80 MHz                 | 45% / 55%  | ±100 PPM         | 20 μs     | TBD ns                                                |

## Clock Network

Table 35: I/O Control Network/Local High-Drive

| Destination | From Pad (max.) | From Array (max.) |
|-------------|-----------------|-------------------|
| I/O (far)   | 1.00 ns         | 1.14 ns           |
| I/O (near)  | 0.63 ns         | 0.78 ns           |
| Skew        | 0.37 ns         | 0.36 ns           |

Figure 49: Dedicated Clock Structure Schematic

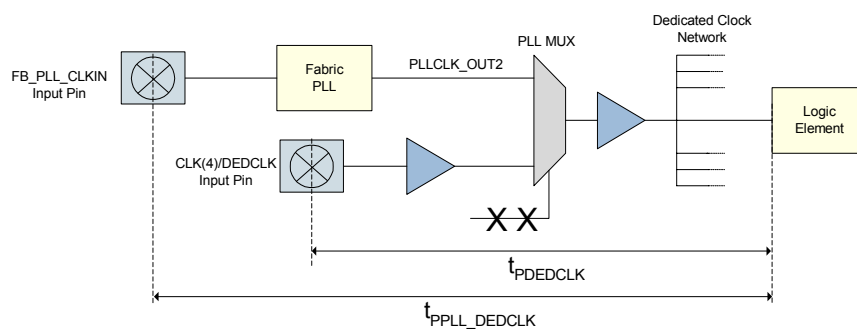

Table 36: Dedicated Clock Network Performance

| Symbol             | Parameters                                                   | Value |         |

| Rising Edge  | 1.7 V/ns  | 0.6 V/ns  |
| Falling Edge | 1.9 V/ns  | 0.6 V/ns  |

Table 43: Fabric Output Slew Rates @ VCCIO(A:D) = 1.8 V, 25° C

|              | Fast Slew | Slow Slew |
|--------------|-----------|-----------|
| Rising Edge  | TBD V/ns  | TBD V/ns  |
| Falling Edge | TBD V/ns  | TBD V/ns  |

Table 44: ASSP Output Slew Rates @ V3V = 3.3 V, 25° C by Signal Groups

| ASSP Output Group <sup>a</sup>   | Slew (V/ns) Maximum |         | Slew (V/ns) Minimum |         |
|----------------------------------|---------------------|---------|---------------------|---------|
|                                  | Rising              | Falling | Rising              | Falling |
| SDRAM Signals (except SD_CLKOUT) | 3.00                | 3.87    | 0.96                | 1.12    |
| SD_CLKOUT                        | 4.20                | 5.30    | 1.50                | 1.95    |
| SRAM Control Signals             | 2.30                | 2/97    | 0.55                | 0.58    |
| PCI Signals                      | 5.35                | 3.20    | 1.90                | 2.43    |
| UART Signals                     | 1.33                | 1.59    | 0.30                | 0.30    |

a. Loads are as follows: SDRAM signals - 35 pF, SD\_CLKOUT = 15 pF, SRAM signals = 50 pF, PCI signals = 10 pF, and UART signals = 50 pF.

## ASSP to Fabric Timing

**Table 45** through **Table 47** list the synchronous and asynchronous timing for the QL903M ASSP to Fabric interface ports and ASSP I/O pins. Note the following regarding the Fabric timing:

- fb\_int is asynchronous and is synchronized inside the core.
- fb\_bigendian is a static signal and reflects the value on the CPU\_BIGENDIAN pin.
- pm\_\* and si\_\* signals are synchronous to the internal MIPS clock which is at least twice the hclk frequency. This internal clock is not driven to the Fabric.
- All AF\_PCI\_\* signals are static.

## ASSP to Fabric Synchronous Output Timing

Table 45: ASSP to Fabric Interface Synchronous Output Timing

| Clock Reference | Signal            | QL903M175<br>t <sub>co</sub> (ns max.) | QL903M200<br>t <sub>co</sub> (ns max.) |
|-----------------|-------------------|----------------------------------------|----------------------------------------|
| hclk            | ahb_hready_in     | 6.05                                   | 5.29                                   |
| hclk            | ahbm_hgrant       | 7.63                                   | 6.68                                   |
| hclk            | ahbm_hrdata(31:0) | 7.94                                   | 6.95                                   |

## Package Thermal Characteristics

Thermal Resistance Equations:

$$\theta_{JC} = (T_J - T_C) / P$$

$$\theta_{JA} = (T_J - T_A) / P$$

$$P_{MAX} = (T_{JMAX} - T_{AMAX}) / \theta_{JA}$$

Parameter Description:

$\theta_{JC}$ : Junction-to-case thermal resistance

$\theta_{JA}$ : Junction-to-ambient thermal resistance

$T_J$ : Junction temperature

$T_C$ : Case temperature

$T_A$ : Ambient temperature

$P$ : Power dissipated by the device while operating

$P_{MAX}$ : The maximum power dissipation for the device

$T_{JMAX}$ : Maximum junction temperature

$T_{AMAX}$ : Maximum ambient temperature

**NOTE:** Maximum junction temperature ( $T_{JMAX}$ ) is 125°C. To calculate the maximum power dissipation for a device package look up  $\theta_{JA}$  from **Table 48**, pick an appropriate  $T_{AMAX}$  and use:

$$P_{MAX} = (125^{\circ}\text{C} - T_{AMAX}) / \theta_{JA}$$

Table 48: Package Thermal Characteristics

| Package Description |              | $\theta_{JA}$ (° C/W) @ Various Flow Rates (m/sec) |      |      |      | $\theta_{JC}$ (° C/W) |
|---------------------|--------------|----------------------------------------------------|------|------|------|-----------------------|
| Pin Count           | Package Type | 0                                                  | 1    | 2    | 2.5  |                       |
| 544                 | PBGA         | 20                                                 | 16.4 | 15.5 | 14.4 | 8.0                   |

## Power vs. Operating Frequency

The basic power equation which best models power consumption is given below:

$$P_{\text{TOTAL}} \text{ (mW)} = 0.350 + f_{\text{Fabric}} [0.0031 \eta_{\text{LC}} + 0.0948 \eta_{\text{CKBF}} + 0.01 \eta_{\text{CLBF}} + 0.0263 \eta_{\text{CKLD}} + 0.543 \eta_{\text{RAM}} + 0.20 \eta_{\text{PLL}} + 0.0035 \eta_{\text{INP}} + 0.0257 \eta_{\text{OUTP}}] + 28.1 f_{\text{asspio}} + 5.55 f_{\text{mips}}$$

Where

|                      |                                                         |
|----------------------|---------------------------------------------------------|
| $\eta_{\text{LC}}$   | = number of logic cells in the design                   |
| $\eta_{\text{CKBF}}$ | = number of clock buffers                               |
| $\eta_{\text{CLBF}}$ | = number of column clock buffers                        |
| $\eta_{\text{CKLD}}$ | = number of loads connected to the column clock buffers |
| $\eta_{\text{RAM}}$  | = number of RAM blocks                                  |
| $\eta_{\text{PLL}}$  | = number of PLLs                                        |
| $\eta_{\text{INP}}$  | = number of input pins                                  |
| $\eta_{\text{OUTP}}$ | = number of output pins                                 |
| $f_{\text{Fabric}}$  | = average switching frequency of Fabric                 |
| $f_{\text{asspio}}$  | = average switching frequency of ASSP I/O signals       |
| $f_{\text{mips}}$    | = CPU operational frequency                             |

**NOTE:** To learn more about power consumption, please refer to Application Note 60 at <http://www.quicklogic.com/images/appnote60.pdf>.

## Power-Up Sequencing

Figure 55: Power-Up Sequencing

When powering up a device, the VCC, VCCIO and V3V rails must take 400  $\mu$ s or longer to reach the maximum value (refer to **Figure 55**).

**NOTE:** Ramping VCC, VCCIO and V3V to the maximum voltage faster than 400  $\mu$ s can cause the device to behave improperly.

For users with a limited power budget, keep  $(V3V - VCC)_{\text{MAX}}$  and  $(VCCIO - VCC)_{\text{MAX}} \leq 500$  mV when ramping up the power supply.

## Board Layout Recommendations

This section describes various recommendations for design and layout of the printed circuit board (PCB) that is used with the QL903M.

### PLL Power Supply Filtering

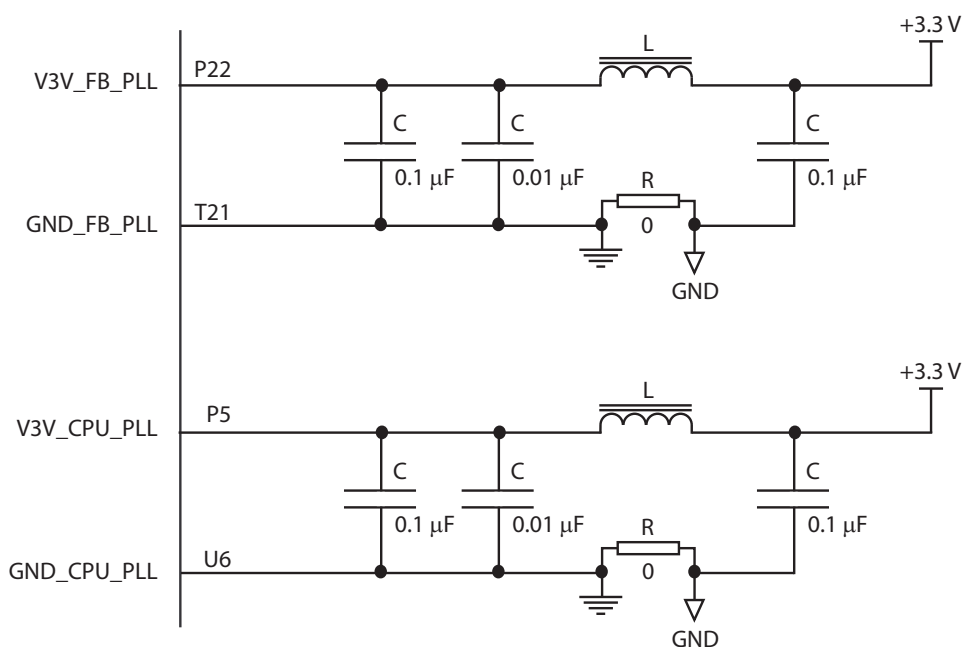

The PLL analog power supply inputs of the QL903M are:

Fabric PLL: GND\_FB\_PLL and V3V\_FB\_PLL

CPU PLL: GND\_CPU\_PLL and V3V\_CPU\_PLL

These signals must be filtered as shown in **Figure 56**:

Figure 56: PLL Power Supply Filtering Circuits

For best performance and noise immunity, separate or split power planes for digital ground (GND), analog ground (FB\_PLL\_GND and CPU\_PLL\_GND), digital  $V_{CC}$  (VCC), digital 3.3 V (V3V) and analog 3.3 V (FB\_PLL\_V3V and CPU\_PLL\_V3V) should be used.

## Bypass Capacitor Guidelines

This section outlines the recommendations for capacitive bypassing for the various digital supplies of the QL903M. **Table 49** indicates the minimum recommended number of 0.1  $\mu$ F and 0.01  $\mu$ F capacitors for each digital supply input on the QL903M. A minimum total quantity of 48 bypass capacitors is recommended.

Table 49: Minimum Recommended Number of Bypass Capacitors for Each Digital Supply Input

| Supply Input | Recommended Number of Capacitors 0.1 $\mu$ F, X7R Type (or better) | Recommended Number of Capacitors 0.01 $\mu$ F, X7R Type (or better) | Totals |
|--------------|--------------------------------------------------------------------|---------------------------------------------------------------------|--------|
| VCC          | 8                                                                  | 8                                                                   | 16     |
| VCCIO(A)     | 2                                                                  | 2                                                                   | 4      |
| VCCIO(B)     | 2                                                                  | 2                                                                   | 4      |
| VCCIO(C)     | 2                                                                  | 2                                                                   | 4      |
| VCCIO(D)     | 2                                                                  | 2                                                                   | 4      |
| V3V          | 8                                                                  | 8                                                                   | 16     |
| Totals:      | 24                                                                 | 24                                                                  | 48     |

**NOTE:** All capacitors should be X7R type (or better) and 0603 package size is recommended.

## Capacitor Placement

Eight capacitors (all for the  $V_{CC}$  supply) should be placed directly under the device (in the area between the 8x8 GND pads in the center of the device and the outer rows of signal pads) on the back side of the PCB. The remaining forty capacitors (for the remainder of  $V_{CC}$  and all other supplies) should be placed around the perimeter of the chip, also preferably on the back side of the board.

Listed below is the proximity location priority (1=highest). Higher priority filters and/or capacitors should be placed closest to the QL903M.

1. PLL bypass capacitors and filter circuitry
2.  $V_{CC}$  bypass capacitors
3. VCCIO/V3V bypass capacitors

## Signal Descriptions

### Pin Descriptions

Table 50: Pin Descriptions

| Pin             | I/O                         | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |                 |             |      |                       |      |               |      |          |      |           |      |             |      |              |      |                    |      |                     |      |                      |      |                    |      |                  |      |                             |
|-----------------|-----------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------|-------------|------|-----------------------|------|---------------|------|----------|------|-----------|------|-------------|------|--------------|------|--------------------|------|---------------------|------|----------------------|------|--------------------|------|------------------|------|-----------------------------|
| PCI Signals     |                             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |                 |             |      |                       |      |               |      |          |      |           |      |             |      |              |      |                    |      |                     |      |                      |      |                    |      |                  |      |                             |
| PCI_AD(31:0)    | I/O                         | <p><b>PCI Address and Data.</b> PCI_AD(31:0) contain the multiplexed address and data. A bus transaction consists of a single address phase (or two address phases for 64-bit addresses) followed by one or more data phases. The QuickMIPS chip supports both read and write bursts.</p> <p>The address phase occurs in the first clock cycle when PCI_FRAME_n is asserted. During the address phase, PCI_AD(31:0) contain a 32-bit physical address. For I/O, this is a byte address; for configuration and memory, it is a DWORD (32-bit) address. During data phases, PCI_AD(7:0) contain the least-significant byte, and PCI_AD(31:24) contain the most-significant byte.</p> <p>Write data is stable and valid when PCI_IRDY_n is asserted; read data is stable and valid when PCI_TRDY_n is asserted. Data is transferred when both PCI_IRDY_n and PCI_TRDY_n are asserted.</p> <p>Connect to GND if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                                                                 |                 |             |      |                       |      |               |      |          |      |           |      |             |      |              |      |                    |      |                     |      |                      |      |                    |      |                  |      |                             |
| PCI_C_BE_n(3:0) | I/O                         | <p><b>Bus Command and Byte Enables.</b> Bus commands and byte enables are multiplexed on PCI_C_BE_n(3:0). During the address phase of a transaction (PCI_FRAME_n is asserted), PCI_C_BE_n(3:0) define the bus command as shown in the following table (only valid combinations are shown).</p> <table><thead><tr><th>PCI_C_BE_n(3:0)</th><th>Bus Command</th></tr></thead><tbody><tr><td>0000</td><td>Interrupt Acknowledge</td></tr><tr><td>0001</td><td>Special Cycle</td></tr><tr><td>0010</td><td>I/O Read</td></tr><tr><td>0011</td><td>I/O Write</td></tr><tr><td>0110</td><td>Memory Read</td></tr><tr><td>0111</td><td>Memory Write</td></tr><tr><td>1010</td><td>Configuration Read</td></tr><tr><td>1011</td><td>Configuration Write</td></tr><tr><td>1100</td><td>Memory Read Multiple</td></tr><tr><td>1101</td><td>Dual Address Cycle</td></tr><tr><td>1110</td><td>Memory Read Line</td></tr><tr><td>1111</td><td>Memory Write and Invalidate</td></tr></tbody></table> <p>During each data phase, PCI_C_BE_n(3:0) are byte enables. The byte enables are valid for the entire data phase and determine which byte lanes contain meaningful data. PCI_C_BE_n(0) applies to byte 0 (PCI_AD(7:0)) and PCI_C_BE_n(3) applies to byte 3 (PCI_AD(31:24)).</p> <p>Connect to GND if the PCI Controller is unused.</p> | PCI_C_BE_n(3:0) | Bus Command | 0000 | Interrupt Acknowledge | 0001 | Special Cycle | 0010 | I/O Read | 0011 | I/O Write | 0110 | Memory Read | 0111 | Memory Write | 1010 | Configuration Read | 1011 | Configuration Write | 1100 | Memory Read Multiple | 1101 | Dual Address Cycle | 1110 | Memory Read Line | 1111 | Memory Write and Invalidate |

| PCI_DEVSEL_n    | I/O                         | <p><b>PCI Device Select.</b> When asserted low, PCI_DEVSEL_n indicates the driving device has decoded its address as the target of the current access. As an input, PCI_DEVSEL_n indicates whether any device on the bus has responded.</p> <p>Connect to 3.3 V if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |                 |             |      |                       |      |               |      |          |      |           |      |             |      |              |      |                    |      |                     |      |                      |      |                    |      |                  |      |                             |

Table 50: Pin Descriptions (Continued)

| Pin         | I/O | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PCI_FRAME_n | I/O | <p><b>PCI Cycle Frame.</b> The current master asserts PCI_FRAME_n to indicate the beginning and duration of a bus transaction. While PCI_FRAME_n is asserted, data transfers continue. When PCI_FRAME_n is deasserted, the transaction is in the final data phase or has completed.</p> <p>Connect to 3.3 V if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                                              |
| PCI_GNT_n   | I   | <p><b>PCI Grant.</b> A low assertion of PCI_GNT_n indicates to the agent that access to the bus has been granted. PCI_GNT_n is ignored while PCI_RST_n is asserted.</p> <p>Connect to 3.3 V if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| PCI_IDSEL   | I   | <p><b>PCI Initialization Device Select.</b> PCI_IDSEL is used as a chip select during configuration read and write transactions (PCI_C_BE_n(3:0) = 1010 or 1011).</p> <p>Connect to GND if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PCI_INTA_n  | O   | <p><b>PCI Interrupt Acknowledge.</b> PCI_INTA_n is a level-sensitive interrupt driven by the QuickMIPS chip. PCI_INTA_n is asserted and deasserted asynchronously to the PCI_CLK. This interrupt remains asserted until the interrupt is cleared.</p> <p>Because the PCI interrupt controller is not built into the QuickMIPS ESP core, this pin is output only. However, such an interrupt controller can be built into the Fabric.</p> <p>Leave unconnected if the PCI Controller is unused.</p>                                                                                                                                                                                                            |
| PCI_IRDY_n  | I/O | <p><b>PCI Initiator Ready.</b> PCI_IRDY_n is used in conjunction with PCI_TRDY_n. The bus master (initiator) asserts PCI_IRDY_n to indicate when there is valid data on PCI_AD(31:0) during a write, or that it is ready to accept data on PCI_AD(31:0) during a read.</p> <p>A data phase is completed when both PCI_IRDY_n and PCI_TRDY_n are asserted. During a write, a low assertion of PCI_IRDY_n indicates that valid data is present on PCI_AD(31:0). During a read, a low assertion of PCI_IRDY_n indicates the master is prepared to accept data. Wait cycles are inserted until both PCI_IRDY_n and PCI_TRDY_n are asserted together.</p> <p>Connect to 3.3 V if the PCI Controller is unused.</p> |
| PCI_PAR     | I/O | <p><b>PCI Parity.</b> Parity is driven high or low to create even parity across PCI_AD(31:0) and PCI_C_BE_n(3:0). The master drives PCI_PAR for address and write data phases; the target drives PCI_PAR for read data phases.</p> <p>Connect to 3.3 V if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                                                                                                   |
| PCI_PERR_n  | I/O | <p><b>PCI Parity Error.</b> PCI_PERR_n indicates the occurrence of a data parity error during all PCI transactions except a Special Cycle. The QuickMIPS chip drives PCI_PERR_n low two clocks following the data when a data parity error is detected. The minimum duration of the deassertion of PCI_PERR_n is one clock for each data phase that a data parity error is detected. (If sequential data phases each have a data parity error, the PCI_PERR_n signal is asserted for more than a single clock.) PCI_PERR_n is driven high for one clock before being 3-stated as with all sustained 3-state signals.</p> <p>Connect to 3.3 V if the PCI Controller is unused.</p>                             |

Table 50: Pin Descriptions (Continued)

| Pin                         | I/O | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|-----|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| PCI_REQ_n                   | O   | <p><b>PCI Request.</b> Assertion of PCI_REQ_n indicates to the arbiter that this agent desires use of the bus. PCI_REQ_n is 3-stated while PCI_RST_n is asserted.</p> <p>Leave unconnected if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| PCI_RST_n                   | I   | <p><b>PCI Reset.</b> Asserting PCI_RST_n low resets the internal state of the QuickMIPS PCI block. When PCI_RST_n is asserted, all PCI output signals are asynchronously 3-stated. PCI_REQ_n and PCI_GNT_n must both be 3-stated (they cannot be driven low or high during reset).</p> <p>The assertion/deassertion of PCI_RST_n can be asynchronous to PCI_CLK.</p> <p>Connect to GND if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                    |
| PCI_SERR_n                  | O   | <p><b>PCI System Error.</b> The QuickMIPS chip asserts PCI_SERR_n to indicate an address parity error, a data parity error on the Special Cycle command, or any other system error where the result is catastrophic. PCI_SERR_n is open drain and is actively driven for a single PCI clock. The assertion of PCI_SERR_n is synchronous to the clock and meets the setup and hold times of all bused signals. However, the restoring of PCI_SERR_n to the deasserted state is accomplished by a weak pull-up (same value as used for s/t/s), which is provided by the central resource not by the signaling agent. This pull-up can take two to three clock periods to fully restore PCI_SERR_n.</p> <p>Leave unconnected if the PCI Controller is unused.</p> |
| PCI_STOP_n                  | I/O | <p><b>PCI Stop.</b> PCI_STOP_n is asserted low to indicate the current target is requesting the master to stop the current transaction. Connect to 3.3 V if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| PCI_TRDY_n                  | I/O | <p><b>PCI Target Ready.</b> PCI_TRDY_n is used in conjunction with PCI_IRDY_n. The current bus slave (target) asserts PCI_TRDY_n to indicate when there is valid data on PCI_AD(31:0) during a read, or that it is ready to accept data on PCI_AD(31:0) during a write.</p> <p>A data phase is completed when both PCI_TRDY_n and PCI_IRDY_n are asserted. During a read, a low assertion of PCI_TRDY_n indicates that valid data is present on PCI_AD(31:0). During a write, a low assertion indicates the target is prepared to accept data. Wait cycles are inserted until both PCI_IRDY_n and PCI_TRDY_n are asserted together.</p> <p>Connect to 3.3 V if the PCI Controller is unused.</p>                                                               |
| PCI_CLK                     | I   | <p><b>PCI Clock.</b> All PCI signals (except PCI_RST_n and PCI_INTA_n) are sampled on the rising edge of PCI_CLK. PCI_CLK operates at speeds up to either 33 MHz or 66 MHz.</p> <p>Connect to GND if the PCI Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Ethernet MAC Signals</b> |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| M1_RXCLK,<br>M2_RXCLK       | I   | <p><b>Ethernet Receive Clock.</b> RXCLK is a continuous clock that provides the timing reference for the transfer of the RXDV and RXD(3:0) signals from the Ethernet PHY Controller to the MAC core. The Ethernet PHY Controller chip sources RXCLK. RXCLK has a frequency equal to 25% of the data rate of the received signal on the Ethernet cable.</p> <p>Connect to GND if the Ethernet Controller is unused.</p>                                                                                                                                                                                                                                                                                                                                         |

| DATA(31:0)                                 | I/O | <b>Memory Data.</b> This 32-bit bus contains the memory read/write data for SRAM and SDRAM accesses.                                                                                                                                                                                                                                                                                                                 |
| OE_n                                       | O   | <b>SRAM Output Enable.</b> OE_n is the active-low output enable to the external SRAM.                                                                                                                                                                                                                                                                                                                                |
| SD_CAS_n                                   | O   | <b>SDRAM Column Address Strobe.</b> SD_CAS_n is the active-low column address strobe for the external SDRAM.                                                                                                                                                                                                                                                                                                         |
| SD_CKE(1:0)                                | O   | <b>SDRAM Clock Enables.</b> If low, these signals indicate to the externally connected SDRAM to enter the power-down state.                                                                                                                                                                                                                                                                                          |
| SD_CLKIN                                   | I   | <b>SDRAM Input Clock.</b> SD_CLKIN should be tied to SD_CLKOUT on the PCB. Internal to the QuickMIPS device, all SDRAM command, address and data signals are synchronized with SD_CLKIN. If a clock buffer is used to drive the SDRAM devices, this buffer should be a zero-delay type buffer, and SD_CLKIN should be tied to one of the buffer outputs.                                                             |
| SD_CLKOUT                                  | O   | <b>SDRAM Output Clock.</b> SD_CLKOUT is the clock source for the externally connected SDRAMs. This signal may be connected to a zero-delay buffer to drive multiple SDRAM devices. SD_CLKOUT is equal in frequency to the internal System Bus clock and hclk. See <a href="#">Table 2</a> for additional details.                                                                                                    |
| SD_CS_n(1:0)                               | O   | <b>SDRAM Output Chip Select.</b> SD_CS_n(1:0) are the active-low chip selects for the external SDRAMs.                                                                                                                                                                                                                                                                                                               |
| SD_DQM(3:0)                                | O   | <b>SDRAM Data Mask.</b> SD_DQM(3:0) are the data masks for DATA(31:0) during SDRAM read and write accesses.<br>SD_DQM(3) corresponds to DATA(31:24)<br>SD_DQM(2) corresponds to DATA(23:16)<br>SD_DQM(1) corresponds to DATA(15:8)<br>SD_DQM(0) corresponds to DATA(7:0)                                                                                                                                             |
| SD_RAS_n                                   | O   | <b>SDRAM Row Address Strobe.</b> SD_RAS_n is the active-low row address strobe for the external SDRAM.                                                                                                                                                                                                                                                                                                               |
| SD_WE_n                                    | O   | <b>SDRAM Write Enable.</b> SD_WE_n is the active-low write enable to the SDRAMs.                                                                                                                                                                                                                                                                                                                                     |
| WE_n                                       | O   | <b>SRAM Write Enable.</b> WE_n indicates whether transactions between the QuickMIPS chip and the external SRAM are reads (WE_n is high) or writes (WE_n is low).                                                                                                                                                                                                                                                     |

| Pin                       | I/O | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------|-----|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| STM                       | I   | <b>QuickLogic Reserved Pin.</b> Tie to GND on the PCB.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| CPU_RESET_n               | I   | <b>Active Low CPU Reset.</b> Asserting this signal low resets the entire ASSP portion of the QuickMIPS device (except for the PCI Controller, which has its own reset input). When low, CPU_RESET_n causes a cold reset exception to the MIPS CPU and halts all internal system clocks. This signal should be asserted for at least five CPU_PLL_CLKIN clock cycles. For reliable operation, the power supply must be stable and the clock must be running before this signal is deasserted.                |
| CPU_WARMRESET_n           | I   | <b>Active Low CPU Warm Reset.</b> Asserting this signal low resets the entire ASSP portion of the QuickMIPS device (except for the PCI Controller, which has its own reset input). When low, CPU_WARMRESET_n causes a warm reset exception to the MIPS CPU, but all system clocks continue to operate. This signal should be asserted for at least five CPU_PLL_CLKIN clock cycles. For reliable operation, the power supply must be stable and the clock must be running before this signal is deasserted. |
| <b>Fabric PLL Signals</b> |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| FB_PLL_CLKIN              | I   | <b>Fabric PLL Input Clock Signal.</b> This is the input reference clock to the Fabric PLL circuit.<br>Connect to GND if the Fabric PLL is not used.                                                                                                                                                                                                                                                                                                                                                         |
| FB_PLL_RESET_n            | I   | <b>Fabric PLL Active Low Reset.</b> If FB_PLL_RESET_n is low, then all PLL outputs are reset to zero.<br>Connect to GND if the Fabric PLL is not used.                                                                                                                                                                                                                                                                                                                                                      |
| FB_PLL_PADOUT             | O   | <b>Fabric PLL Output Off Chip.</b> This is the PLL output clock driven off chip. This output runs at the PLL VCO ( $F_{VCO}$ ) frequency determined by the M(1:0) input.<br>Leave unconnected if unused.                                                                                                                                                                                                                                                                                                    |
| <b>ASSP PLL Signals</b>   |     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| CPU_PLL_CLKIN             | I   | <b>Input Clock Signal.</b> This clock input is the reference clock used by the CPU PLL. The frequency of the clock on this input is multiplied by eight to drive the MIPS CPU.                                                                                                                                                                                                                                                                                                                              |
| CPU_PLL_ENABLE_n          | I   | <b>Active Low PLL Enable Signal.</b> This signal must be low to enable the ASSP-side PLL. If CPU_PLL_ENABLE_n is held high and CPU_PLL_BYPASS is held low, the QL903M is put into a power saving quiescent state.                                                                                                                                                                                                                                                                                           |
| CPU_PLL_BYPASS            | I   | <b>PLL Bypass.</b> When high, the 8X multiplication of the input clock is not performed and the output clocks are equal to the input frequency.                                                                                                                                                                                                                                                                                                                                                             |
| CPU_PLL_CLKOUT            | O   | <b>Output Clock Signal from the PLL.</b> This output operates at the same frequency that is driven to the MIPS CPU.<br>Leave unconnected if unused.                                                                                                                                                                                                                                                                                                                                                         |
| CPU_PLL_LOCK              | O   | <b>PLL Lock.</b> The lock output indicates when the PLL is locked to the input clock and is producing valid output clocks.<br>Leave unconnected if unused.                                                                                                                                                                                                                                                                                                                                                  |
| CPU_PLL_DIV(1:0)          | I   | <b>System Bus Clock to MIPS CPU Clock Ratio Control.</b> See <b>Table 2</b> for more details.                                                                                                                                                                                                                                                                                                                                                                                                               |

Table 50: Pin Descriptions (Continued)

| Pin                             | I/O | Function                                                                                                                                                                                                                                                                                                                                                    |

## ASSP Fabric Port Descriptions

Table 51: ASSP to Fabric Port Descriptions

| Port                               | I/O <sup>a</sup> | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------------------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Ethernet Controller Signals</b> |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| M1_COL,<br>M2_COL                  | I                | <p><b>Ethernet Collision Detected.</b> The external Ethernet PHY Controller chip asserts COL high upon detection of a collision on the medium. COL remains asserted while the collision condition persists.</p> <p>The transitions on the COL signal are not synchronous to either the TXCLK or the RXCLK.</p> <p>The QuickMIPS MAC core ignores the COL signal when operating in the full-duplex mode.</p>                                                                                               |
| M1_CRS,<br>M2_CRS                  | I                | <p><b>Ethernet Carrier Sense.</b> The external Ethernet PHY Controller chip asserts CRS high when either transmit or receive medium is non-idle. The PHY deasserts CRS low when both the transmit and receive medium are idle. The PHY must ensure that CRS remains asserted throughout the duration of a collision condition.</p> <p>The transitions on the CRS signal are not synchronous to either the TXCLK or the RXCLK.</p>                                                                         |
| M1_MDC,<br>M2_MDC                  | O                | <p><b>Ethernet Management Data Clock.</b> MDC is sourced by the MAC core to the Ethernet PHY Controller as the timing reference for transfer of information on the MDI/MDO signals. MDC is an aperiodic signal that has no maximum high or low times. The minimum high and low times for MDC are 160 ns each, and the minimum period for MDC is 400 ns, regardless of the nominal period of TXCLK and RXCLK.</p>                                                                                          |
| M1_MDI,<br>M2_MDI                  | I                | <p><b>Ethernet Management Data In.</b> This is the data input signal from the Ethernet PHY Controller. The PHY drives the Read Data synchronously with respect to the MDC clock during the read cycles.</p>                                                                                                                                                                                                                                                                                               |
| M1_MDO,<br>M2_MDO                  | O                | <p><b>Ethernet Management Data Out.</b> This is the data output signal from the MAC core that drives the control information during the Read/Write cycles to the External PHY Controller. The MAC core drives the MDO signal synchronously with respect to the MDC.</p>                                                                                                                                                                                                                                   |
| M1_MDO_EN_N,<br>M2_MDO_EN_N        | O                | <p><b>Ethernet Management Data Output enable.</b> This signal, when low, enables the Fabric IO driver to drive Mn_MDO off chip.</p>                                                                                                                                                                                                                                                                                                                                                                       |
| M1_RXD(3:0),<br>M2_RXD(3:0)        | I                | <p><b>Ethernet Receive Data.</b> RXD(3:0) transition synchronously with respect to RXCLK. The Ethernet PHY Controller chip drives RXD(3:0). For each RXCLK period in which RXDV is asserted, RXD(3:0) transfer four bits of recovered data from the PHY to the MAC core. RXD0 is the least-significant bit. While RXDV is deasserted low, RXD(3:0) has no effect on the MAC core.</p>                                                                                                                     |
| M1_RXDV,<br>M2_RXDV                | I                | <p><b>Ethernet Receive Data Valid.</b> The Ethernet PHY Controller asserts RXDV high to indicate to the MAC core that it is presenting the recovered and decoded data bits on RXD(3:0) and that the data on RXD(3:0) is synchronous to RXCLK. RXDV transitions synchronously with respect to RXCLK. RXDV remains asserted continuously from the first recovered nibble of the frame through the final recovered nibble, and is deasserted low prior to the first RXCLK that follows the final nibble.</p> |

Table 51: ASSP to Fabric Port Descriptions (Continued)

| Port                                       | I/O <sup>a</sup> | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| M1_RXER,<br>M2_RXER                        | I                | <b>Ethernet Receive Error.</b> The Ethernet PHY Controller chip asserts RXER high for one or more RXCLK periods to indicate to the MAC core that an error (a coding error or any error that the PHY is capable of detecting that is otherwise undetectable by the MAC) was detected somewhere in the frame presently being transferred from the PHY to the MAC core. RXER transitions synchronously with respect to RXCLK. While RXDV is deasserted low, RXER has no effect on the MAC core. |
| M1_TXD(3:0),<br>M2_TXD(3:0)                | O                | <b>Ethernet Transmit Data.</b> The QuickMIPS MAC core drives TXD(3:0). TXD(3:0) transition synchronously with respect to TXCLK. For each TXCLK period in which TXEN is asserted, TXD(3:0) have the data to be accepted by the Ethernet PHY Controller chip. TXD0 is the least-significant bit. While TXEN is deasserted, ignore the data presented on TXD(3:0).                                                                                                                              |
| M1_TXEN,<br>M2_TXEN                        | O                | <b>Ethernet Transmit Enable.</b> A high assertion on TXEN indicates that the MAC core is presenting nibbles on the MII for transmission. The QuickMIPS MAC core asserts TXEN with the first nibble of the preamble and holds TXEN asserted while all nibbles to be transmitted are presented to the MII. TXEN is deasserted low prior to the first TXCLK following the final nibble of the frame. TXEN is transitions synchronously with respect to TXCLK.                                   |
| <b>On-Chip System SRAM Block 1 Signals</b> |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| SR1_ADDR(11:2)                             | I                | <b>On-Chip SRAM Block 1 Address.</b> This 10-bit address is the memory address for block 1 of the On-Chip SRAM.                                                                                                                                                                                                                                                                                                                                                                              |
| SR1_CLK                                    | I                | <b>On-Chip SRAM Block 1 Clock.</b> This clock drives block 1 of the On-Chip SRAM. When SRAM block 1 is connected to the Fabric, all SRAM block 1 IO signals are synchronous with this clock.                                                                                                                                                                                                                                                                                                 |

| pm_dtlbhit            | O                | <b>Performance Monitor Data TLB Hit.</b> This signal is asserted whenever there is a hit in the data TLB. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                                                              |
| pm_dtlbmiss           | O                | <b>Performance Monitor data TLB Miss.</b> This signal is asserted whenever there is a miss in the data TLB. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                                                            |
| pm_icachehit          | O                | <b>Performance Monitor Instruction Cache Hit.</b> This signal is asserted whenever there is an instruction-cache hit. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                                                  |
| pm_icachemiss         | O                | <b>Performance Monitor Instruction Cache Miss.</b> This signal is asserted whenever there is an instruction-cache miss. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                                                |
| pm_instncomplete      | O                | <b>Performance Monitor Instruction Complete.</b> This signal is asserted each time an instruction completes in the pipeline. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                                           |
| pm_itlbhit            | O                | <b>Performance Monitor Instruction TLB Hit.</b> This signal is asserted whenever there is an instruction TLB hit. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                                                      |
| pm_itlbmiss           | O                | <b>Performance Monitor Instruction TLB Miss.</b> This signal is asserted whenever there is an instruction TLB miss. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                                                    |
| pm_jtlbhit            | O                | <b>Performance Monitor Joint TLB Hit.</b> This signal is asserted whenever there is a joint TLB hit. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                                                                   |
| pm_jtlbmiss           | O                | <b>Performance Monitor Joint TLB Miss.</b> This signal is asserted whenever there is a joint TLB miss. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                                                                 |
| pm_wtbmerge           | O                | <b>Performance Monitor Write-Through Merge.</b> This signal is asserted whenever there is a successful merge in the write-through buffer. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                              |
| pm_wtbnomerge         | O                | <b>Performance Monitor Write-Through Non-Merge.</b> This signal is asserted whenever a non-merging store is written to the write-through buffer. This signal is synchronous with CPU_PLL_CLKOUT.                                                                                       |
| si_rp                 | O                | <b>Reduce Power Indicator to Fabric.</b> This signal represents the state of the RP bit (27) in the MIPS CP0 Status register. Software can write this bit to indicate that the device can enter a reduced power mode. This signal is synchronous with CPU_PLL_CLKOUT.                  |
| si_sleep              | O                | <b>Sleep Indicator to Fabric.</b> This signal is asserted by the MIPS core whenever the WAIT instruction is executed. The assertion of this signal indicates that the clock has stopped and that the core is waiting for an interrupt. This signal is synchronous with CPU_PLL_CLKOUT. |
| <b>CPU PLL Status</b> |                  |                                                                                                                                                                                                                                                                                        |
| io_mips_pll_lock      | O                | <b>PLL Lock Indicator.</b> This signal, when high, indicates to the Fabric that the ASSP PLL has achieved phase lock on the incoming reference clock signal.                                                                                                                           |

Table 51: ASSP to Fabric Port Descriptions (Continued)

| Port                              | I/O <sup>a</sup> | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------------------|------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PCI Configuration Settings</b> |                  |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| AF_PCI_CFGDONE                    | I                | <b>PCI Configuration Done.</b> This signal represents the initial value (after reset) of the Config Done bit in the PCI DMA registers. After reset, the value of this register may be overwritten through the AHB. The purpose for this register is to disable the PCI interface until the MIPS processor is ready. This may be useful when the read-only ID registers in the PCI configuration space will be over-written by the MIPS processor, which will require some time. While this register is 0, retries will be signaled on the PCI bus, thus signaling that the QuickMIPS device is not ready, and the PCI transaction should be tried again at a later time. Note that the PCI Specification limits the length of time that a device can retry a transaction, and states the amount of time after the PCI reset is deasserted when a PCI configuration cycle may occur. In an embedded system, however, a designer may choose to violate certain PCI specifications if he/she knows it will not have a detrimental impact on the system. This signal is tie-low or tie-high in the Fabric only. |
| AF_PCI_CLASSCODE(23:0)            | I                | <b>PCI Class Code.</b> These signals represent the initial value (after reset) of the Class Code bits in the PCI Configuration Registers. After reset, the value of this register may be overwritten through the AHB. The Class Code register is used to identify the generic function of the device and, in some cases, a specific register-level programming interface. These signals are tie-low or tie-high in the Fabric only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| AF_PCI_DEVID(15:0)                | I                | <b>PCI Device ID.</b> These signals represent the initial value (after reset) of the Device ID bits in the PCI Configuration Registers. After reset, the value of this register may be overwritten through the AHB. This field identifies the particular PCI device. This identifier is allocated by the vendor. These signals are tie-low or tie-high in the Fabric only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| AF_PCI_HOST                       | I                | <b>PCI Host.</b> This signal represents the initial value (after reset) of the Host Mode bit in the PCI DMA registers. After reset, the value of this register may be overwritten through the AHB. This register controls whether the QuickMIPS device acts as the PCI system host or is a satellite device. A system host must configure itself as well as all the devices on the PCI bus, whereas a satellite device will be configured by another device (the host) of the PCI system. Note that while in host mode, the PCI configuration registers may only be accessed by the AHB, but while in satellite (non-host) mode, the PCI configuration registers may only be accessed by the PCI bus. This signal is tie-low or tie-high in the Fabric only.                                                                                                                                                                                                                                                                                                                                                |
| AF_PCI_MAXLAT(7:0)                | I                | <b>PCI Maximum Latency.</b> These signals represent the initial value (after reset) of the Max Latency bits in the PCI Configuration Registers. After reset, the value of this register may be overwritten through the AHB. This register is used for specifying how often the device needs to gain access to PCI bus. These signals are tie-low or tie-high in the Fabric only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| AF_PCI_MINGNT(7:0)                | I                | <b>PCI Minimum Grant.</b> These signals represent the initial value (after reset) of the Min Grant bits in the PCI Configuration Registers. After reset, the value of this register may be overwritten through the AHB. This register is used for specifying how long a burst period the device needs assuming a clock rate of 33 MHz. These signals are tie-low or tie-high in the Fabric only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| AF_PCI_REVID(7:0)                 | I                | <b>PCI Revision ID.</b> These signals represent the initial value (after reset) of the Revision ID bits in the PCI Configuration Registers. After reset, the value of this register may be overwritten through the AHB. This register specifies a device specific revision identifier. The value is chosen by the vendor (zero is an acceptable value). This field should be viewed as a vendor defined extension to the Device ID. These signals are tie-low or tie-high in the Fabric only.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Table 51: ASSP to Fabric Port Descriptions (Continued)

| Port                   | I/O <sup>a</sup> | Function                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------------------|------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AF_PCI_SUBSYSID(15:0)  | I                | <b>PCI Subsystem ID.</b> These signals represent the initial value (after reset) of the Subsystem ID bits in the PCI Configuration Registers. After reset, the value of this register may be overwritten through the AHB. These registers are used to uniquely identify the expansion board or subsystem where the PCI device resides. They provide a mechanism for expansion board vendors to distinguish their boards from one another even though the boards may have the same PCI controller on them. These signals are tie-low or tie-high in the Fabric only.               |
| AF_PCI_SUBSYSVID(15:0) | I                | <b>PCI Subsystem Vendor ID.</b> These signals represent the initial value (after reset) of the Subsystem Vendor ID bits in the PCI Configuration Registers. After reset, the value of this register may be overwritten through the AHB. These registers are used to uniquely identify the expansion board or subsystem where the PCI device resides. They provide a mechanism for expansion board vendors to distinguish their boards from one another even though the boards may have the same PCI controller on them. These signals are tie-low or tie-high in the Fabric only. |
| AF_PCI_VENID(15:0)     | I                | <b>PCI Vendor ID.</b> These signals represent the initial value (after reset) of the Vendor ID bits in the PCI Configuration Registers. After reset, the value of this register may be overwritten through the AHB. This field identifies the manufacturer of the device. Valid vendor identifiers are allocated by the PCI SIG to ensure uniqueness. These signals are tie-low or tie-high in the Fabric only.                                                                                                                                                                   |

a. Interface direction is specified with respect to the ASSP portion of the device. I designates an input to the ASSP and O designates an output from the ASSP.

| D        | July 2003      | Judd Heape and Kathleen Murchek<br>General clean-up of document text and figures. Added ECU and Dual-Port RAM signals. Added text to ASSP I/O DC Characteristics and ASSP to Fabric Interface Output Timing tables. Added new section - Board Layout Recommendations.<br>Replaced Advanced Clocks Network section.                                                                                                                                                                                                                                     |
| E        | July 2003      | Judd Heape and Kathleen Murchek<br>New PLL power supply filtering illustration and general clean-up of document text.<br>Modified Multiple I/O Banks figure.                                                                                                                                                                                                                                                                                                                                                                                           |
| F        | December 2003  | Judd Heape and Kathleen Murchek<br>Changed $T_{jmax}$ number from 150°C to 125°C in Package Thermal Characteristics section. Added $I_{CC(STATIC)}$ row to DC Characteristics table.<br>Added an AHB Master and AHB Slave Interface Signals section with an ahb_hready_in row to ASSP to Fabric Port Descriptions table.<br>Changed $V_{CC}$ supply specification to $1.95 \pm 0.05$ V.                                                                                                                                                                |
| G        | March 2004     | Judd Heape and Kathleen Murchek<br>Removed Fabric RAM modes 512x4 and 1024x2.<br>Updated AC and DC Characteristics including all Fabric timing and ASSP to Fabric interface timing.<br>Added Fabric PLL timing data and modified clock network figures.<br>Added System SRAM timing data and added timing diagrams.<br>Modified Power-Up Sequencing section.<br>Modified security and flexibility fuse descriptions in JTAG section.<br>Modified EJTAG pin descriptions.<br>Added Fabric I/O voltage and current graphs to DC Characteristics section. |
| H        | September 2004 | Judd Heape and Kathleen Murchek<br>Removed $I_{FAB\_PLL}$ and $I_{CPU\_PLL}$ sections from DC Characteristics table.<br>Changed all instances of $V_{CC\_FB\_PLL}$ and $V_{CC\_CPU\_PLL}$ to $V_{CC}$ .<br>Removed $V_{CC\_FB\_PLL}$ and $V_{CC\_CPU\_PLL}$ from pin description table and PLL Power Supply Filtering Circuits figure.<br>Removed instances of analog $V_{CC}$ , $FB\_PLL\_VCC$ and $CPU\_PLL\_VCC$ from PLL Power Supply Filtering section.<br>Updated text and tables in Fabric PLL Signals section                                  |
