

TPA6010A4

STEREO 2-W AUDIO POWER AMPLIFIER WITH BASS BOOST AND DC VOLUME CONTROL

SLOS268 – JUNE 2000

- Compatible With PC 99 Desktop Line-Out Into 10-k Ω Load
- Compatible With PC 99 Portable Into 8- Ω Load
- Internal Gain Control, Which Eliminates External Gain-Setting Resistors
- DC Volume and Gain Control Adjustable From 34 dB to –86 dB
- Bass Boost
- Buffered Docking Station Outputs
- 2-W/Ch Output Power Into 3- Ω Load
- PC-Beep Input
- Depop Circuitry
- Stereo Input MUX
- Fully Differential Input
- Low Supply Current and Shutdown Current
- Surface-Mount Power Packaging 28-Pin TSSOP PowerPAD™

description

The TPA6010A4 is a stereo audio power amplifier in a 28-pin TSSOP thermally enhanced package capable of delivering 2 W of continuous RMS output power into 3- Ω loads. When driving 1 W into 8- Ω speakers, the TPA6010A4 has less than 0.22% THD+N across its specified frequency range.

The TPA6010A4 has several features optimized for notebook PCs including bass boost, docking station outputs, dc volume control, and dc gain control.

The TPA6010A4 has buffer and volume control gain stages that are set by dc voltages. The buffer has differential input and differential output. The gain of the buffer, which is controlled by the dc voltage on the BUFFGAIN terminal, is adjustable from –46 dB to 14 dB. The docking station output is 6 dB lower than the buffer gain because the buffer has a differential output and the docking station output is taken from just one of the buffer outputs. The volume control amplifier is adjustable from –34 dB to 20 dB in the BTL mode and is 6 dB lower in the SE mode. The volume control stage is adjustable by dc voltage on the VOLUME terminal. The amplifier gain from input-to-speaker is the sum of the volume control and the buffer gain. The input-to-speaker gain is adjustable from –86 dB to 34 dB in the BTL mode and –92 dB to 28 dB in the SE mode.

The bass boost of the amplifier sums the right and left inputs, adds gain, filters out the high frequencies, and then adds the bass boost signal back into the output power amplifier. The frequency of the bass boost is adjusted by adding an RC filter from BBOUT to BBIN. The gain of the bass boost is set to 12 dB if the same bass is present in both the right and left channels. If the bass is present in just one of the channels, the gain of the bass is set to 9.5 dB. The gain can be reduced by adding a voltage divider from BBIN to BBOUT. If not using the bass boost, pull the BBENABLE pin low.

Please be aware that an important notice concerning availability, standard warranty, and use in critical applications of Texas Instruments semiconductor products and disclaimers thereto appears at the end of this data sheet.

PowerPAD is a trademark of Texas Instruments.

PRODUCTION DATA information is current as of publication date. Products conform to specifications per the terms of Texas Instruments standard warranty. Production processing does not necessarily include testing of all parameters.

TPA6010A4

STEREO 2-W AUDIO POWER AMPLIFIER WITH BASS BOOST AND DC VOLUME CONTROL

SLOS268 – JUNE 2000

The PowerPAD™ package (PWP) delivers a level of thermal performance that was previously achievable only in TO-220-type packages. Thermal impedances of approximately 35°C/W are truly realized in multilayer PCB applications. This allows the TPA6010A4 to operate at full power into 8-Ω loads at ambient temperatures of 85°C.

functional block diagram

STEREO 2-W AUDIO POWER AMPLIFIER WITH
BASS BOOST AND DC VOLUME CONTROL

SLOS268 – JUNE 2000

AVAILABLE OPTIONS

T_A	PACKAGED DEVICE
	TSSOP [†] (PWP)
–40°C to 85°C	TPA6010A4PWP

[†] The PWP package is available taped and reeled. To order a taped and reeled part, add the suffix R to the part number (e.g., TPA6010A4PWPR).

Terminal Functions

TERMINAL NAME	NO.	I/O	DESCRIPTION
BBENABLE	3	I	Bass boost circuitry is active when high. Bass boost circuitry is shut down when low.
BBIN	21	I	BBIN is the buffered input to the power amplifier from the bass boost circuitry.
BBOUT	20	O	BBOUT is the bass boost output. A low pass filter must be placed from BBOUT to BBIN to select the low frequencies to be boosted.
BYPASS	4		Tap to voltage divider for internal midsupply bias generator
CLK	27	I	If a 47-nF capacitor is attached, the TPA6010A4 generates an internal clock. An external clock can override the internal clock input to this terminal.
BUFFGAIN	24	I	The gain of the dockout buffer is adjustable from –52dB to 8 dB to LDOCKOUT and RDOCKOUT, and is set by a dc voltage from 0 V to 3.54 V. When the dc level is over 3.54 V, the device is muted.
GND	1, 15		Ground connection for circuitry. Connected to thermal pad.
HP/LINE	13	I	MUX control input, hold high to select LHPIN or RHPIN, hold low to select LLINEIN or RLINEIN.
LHPIN	6	I	Left channel headphone input, selected when HP/LINE is held high
LIN	5	I	Common left input for fully differential input. AC ground for single-ended inputs
LLINEIN	7	I	Left channel line negative input, selected when HP/LINE is held low
LDOCKOUT	26	O	LDOCKOUT is the buffered output of LLINEIN or LHPIN.
LOUT+	2	O	Left channel positive output in BTL mode and positive output in SE mode
LOUT–	28	O	Left channel negative output in BTL mode and high-impedance in SE mode
PC-BEEP	8	I	The input for PC Beep mode. PC-BEEP is enabled when a > 1-V (peak-to-peak) square wave is input to PC-BEEP.
PVDD	19, 25	I	Power supply for output stage
RHPIN	10	I	Right channel headphone input, selected when HP/LINE is held high
RIN	11	I	Common right input for fully differential input. AC ground for single-ended inputs
RLINEIN	9	I	Right channel line input, selected when HP/LINE is held low
RDOCKOUT	18	O	RDOCKOUT is the buffered output of RLINEIN or RHPIN.
ROUT+	14	O	Right channel positive output in BTL mode and positive output in SE mode
ROUT–	16	O	Right channel negative output in BTL mode and high-impedance in SE mode
SE/BTL	17	I	Input MUX control input. When this terminal is held high, the LHPIN or RHPIN and SE output is selected. When this terminal is held low, the LLINEIN or RLINEIN and BTL output are selected.
SHUTDOWN	12	I	When held low, this terminal places the entire device, except PC-BEEP detect circuitry, in shutdown mode.
VDD	22	I	Analog VDD input supply. This terminal needs to be isolated from PVDD to achieve highest performance.
VOLUME	23	I	VOLUME detects the dc level at the terminal and sets the gain for 31 discrete steps covering a range of 20 dB to –40 dB for dc levels of 0.15 V to 3.54. When the dc level is over 3.54 V, the device is muted.

NOTE: The overall input-to-speaker gain is the sum of the internal buffer gain and volume gain found in Table 1. Therefore, the total input-to-speaker gain ranges between -86 dB and 34 dB in the BTL mode and between -92 dB and 28 dB in the SE mode.

POST OFFICE BOX 655303 • DALLAS, TEXAS 75265

APPLICATION INFORMATION

NOTE A: A 0.1 µF ceramic capacitor should be placed as close as possible to the IC. For filtering lower-frequency noise signals, a larger electrolytic capacitor of 10 µF or greater should be placed near the audio power amplifier.

NOTE B: A DC-blocking capacitor should be placed at each input to the amplifier in the docking station, as the RDOCKOUT and LDOCKOUT pins are biased to $V_{DD}/2$.

Figure 1. Typical TPA6010A4 Application Circuit Using Single-Ended Inputs and Input MUX

Figure 2. Typical TPA6010A4 Application Circuit Using Differential Inputs

APPLICATION INFORMATION

input resistance

Each gain setting is achieved by varying the input resistance of the amplifier, which can range from its smallest value to over 6 times that value. As a result, if a single capacitor is used in the input high pass filter, the –3 dB or cut-off frequency will also change by over 6 times. If an additional resistor is connected from the input pin of the amplifier to ground, as shown in the figure below, the variation of the cut-off frequency will be much reduced.

Figure 3. Resistor on Input for Cut-Off Frequency

The input resistance at each gain setting is given in Figure 3.

The –3 dB frequency can be calculated using the following formula:

$$f_{-3\text{ dB}} = \frac{1}{2\pi C(R \parallel R_I)} \quad (1)$$

If the filter must be more accurate, the value of the capacitor should be increased while value of the resistor to ground should be decreased. In addition, the order of the filter could be increased.

input capacitor, C_I

In the typical application an input capacitor, C_I , is required to allow the amplifier to bias the input signal to the proper dc level for optimum operation. In this case, C_I and the input impedance of the amplifier, Z_I , form a high-pass filter with the corner frequency determined in equation 2.

TPA6010A4

STEREO 2-W AUDIO POWER AMPLIFIER WITH BASS BOOST AND DC VOLUME CONTROL

SLOS268 – JUNE 2000

APPLICATION INFORMATION

input capacitor, C_I (continued)

The value of C_I is important to consider as it directly affects the bass (low frequency) performance of the circuit. Consider the example where Z_I is 710 k Ω and the specification calls for a flat bass response down to 40 Hz. Equation 2 is reconfigured as equation 3.

$$C_I = \frac{1}{2\pi Z_I f_c} \quad (3)$$

In this example, C_I is 5.6 nF so one would likely choose a value in the range of 5.6 nF to 1 μ F. A further consideration for this capacitor is the leakage path from the input source through the input network (C_I) and the feedback network to the load. This leakage current creates a dc offset voltage at the input to the amplifier that reduces useful headroom, especially in high gain applications. For this reason a low-leakage tantalum or ceramic capacitor is the best choice. When polarized capacitors are used, the positive side of the capacitor should face the amplifier input in most applications as the dc level there is held at $V_{DD}/2$, which is likely higher than the source dc level. Note that it is important to confirm the capacitor polarity in the application.

power supply decoupling, C_S

The TPA6010A4 is a high-performance CMOS audio amplifier that requires adequate power supply decoupling to ensure the output total harmonic distortion (THD) is as low as possible. Power supply decoupling also prevents oscillations for long lead lengths between the amplifier and the speaker. The optimum decoupling is achieved by using two capacitors of different types that target different types of noise on the power supply leads. For higher frequency transients, spikes, or digital hash on the line, a good low equivalent-series-resistance (ESR) ceramic capacitor, typically 0.1 μ F placed as close as possible to the device V_{DD} lead works best. For filtering lower-frequency noise signals, a larger aluminum electrolytic capacitor of 10 μ F or greater placed near the audio power amplifier is recommended.

midrail bypass capacitor, C_{BYP}

The midrail bypass capacitor, C_{BYP} , is the most critical capacitor and serves several important functions. During startup or recovery from shutdown mode, C_{BYP} determines the rate at which the amplifier starts up. The second function is to reduce noise produced by the power supply caused by coupling into the output drive signal. This noise is from the midrail generation circuit internal to the amplifier, which appears as degraded PSRR and THD+N.

Bypass capacitor, C_{BYP} , values of 0.47 μ F to 1 μ F ceramic or tantalum low-ESR capacitors are recommended for the best THD and noise performance.

APPLICATION INFORMATION

bass boost operation

The bass boost feature of the TPA6010A4 sums the left and right inputs, adds gain, filters out the high frequencies, and adds the bass-boosted signal back into the current-gain stage of the amplifier. The cutoff frequency is set by R_{BB} and C_{BB} as shown in equation 4.

$$f_c = \frac{1}{2\pi R_{BB} C_{BB}} \quad (4)$$

The gain of the bass boost is set internally at 12 dB if bass is present in both the right and left channels. If bass is only present in one of the channels, the boost is reduced to 9.5 dB. The bass boost gain may also be reduced by adding an L-pad voltage divider between the R_{BB} - C_{BB} filter and the BBIN pin. An example circuit is shown in figure 4.

Figure 4. L-Pad Voltage Divider Circuit

The total bass boost gain may be determined by using equation 5.

$$\begin{aligned} \text{Bass Boost Gain} &= 12 \text{ dB} + 20\text{Log} \left(\frac{R2}{R1 + R2} \right) && \text{(bass present on both channels)} \\ &&& (5) \\ \text{Bass Boost Gain} &= 9.5 \text{ dB} + 20\text{Log} \left(\frac{R2}{R1 + R2} \right) && \text{(bass present on only one channel)} \end{aligned}$$

Consider the following example application. The desired cutoff frequency for the bass boost is 300 Hz and the desired bass boost gain is 6 dB. The filter components could be $R_{BB} = 1.1 \text{ k}\Omega$ and $C_{BB} = 0.47 \text{ }\mu\text{F}$, while the L-pad components could be $R1 = R2 = 10 \text{ k}\Omega$.

If the bass boost feature is not to be used or if the user wishes to disable the boost, the BBENABLE pin should be pulled low.

Finally, as illustrated in the functional block diagram, the bass boost is only applied to the speaker outputs, not to the docking station outputs.

APPLICATION INFORMATION

output coupling capacitor, C_C

In the typical single-supply SE configuration, an output coupling capacitor (C_C) is required to block the dc bias at the output of the amplifier thus preventing dc currents in the load. As with the input coupling capacitor, the output coupling capacitor and impedance of the load form a high-pass filter governed by equation 6.

$$f_c = \frac{1}{2\pi R_L C_C}$$

(6)

The main disadvantage, from a performance standpoint, is the load impedances are typically small, which drives the low-frequency corner higher degrading the bass response. Large values of C_C are required to pass low frequencies into the load. Consider the example where a C_C of 330 μ F is chosen and loads vary from 3 Ω , 4 Ω , 8 Ω , 32 Ω , 10 k Ω , and 47 k Ω . Table 2 summarizes the frequency response characteristics of each configuration.

Table 2. Common Load Impedances vs Low Frequency Output Characteristics in SE Mode

R_L	C_C	LOWEST FREQUENCY
3 Ω	330 μ F	161 Hz
4 Ω	330 μ F	120 Hz
8 Ω	330 μ F	60 Hz
32 Ω	330 μ F	15 Hz
10,000 Ω	330 μ F	0.05 Hz
47,000 Ω	330 μ F	0.01 Hz

As Table 2 indicates, most of the bass response is attenuated into a 4- Ω load, an 8- Ω load is adequate, headphone response is good, and drive into line level inputs (a home stereo for example) is exceptional.

using low-ESR capacitors

Low-ESR capacitors are recommended throughout this applications section. A real (as opposed to ideal) capacitor can be modeled simply as a resistor in series with an ideal capacitor. The voltage drop across this resistor minimizes the beneficial effects of the capacitor in the circuit. The lower the equivalent value of this resistance the more the real capacitor behaves like an ideal capacitor.

APPLICATION INFORMATION

bridged-tied load versus single-ended mode

Figure 5 shows a Class-AB audio power amplifier (APA) in a BTL configuration. The TPA6010A4 BTL amplifier consists of two Class-AB amplifiers driving both ends of the load. There are several potential benefits to this differential drive configuration but initially consider power to the load. The differential drive to the speaker means that as one side is slewing up, the other side is slewing down, and vice versa. This in effect doubles the voltage swing on the load as compared to a ground referenced load. Plugging $2 \times V_{O(PP)}$ into the power equation, where voltage is squared, yields $4 \times$ the output power from the same supply rail and load impedance (see equation 7).

$$V_{(rms)} = \frac{V_{O(PP)}}{2\sqrt{2}} \quad (7)$$

$$\text{Power} = \frac{V_{(rms)}^2}{R_L}$$

Figure 5. Bridge-Tied Load Configuration

APPLICATION INFORMATION

In a typical computer sound channel operating at 5 V, bridging raises the power into an 8-Ω speaker from a singled-ended (SE, ground reference) limit of 250 mW to 1 W. In sound power that is a 6-dB improvement — which is loudness that can be heard. In addition to increased power there are frequency response concerns. Consider the single-supply SE configuration shown in Figure 6. A coupling capacitor is required to block the dc offset voltage from reaching the load. These capacitors can be quite large (approximately 33 μF to 1000 μF) so they tend to be expensive, heavy, occupy valuable PCB area, and have the additional drawback of limiting low-frequency performance of the system. This frequency limiting effect is due to the high pass filter network created with the speaker impedance and the coupling capacitance and is calculated with equation 8.

$$f_c = \frac{1}{2\pi R_L C_C} \quad (8)$$

For example, a 68-μF capacitor with an 8-Ω speaker would attenuate low frequencies below 293 Hz. The BTL configuration cancels the dc offsets, which eliminates the need for the blocking capacitors. Low-frequency performance is then limited only by the input network and speaker response. Cost and PCB space are also minimized by eliminating the bulky coupling capacitor.

Figure 6. Single-Ended Configuration and Frequency Response

Increasing power to the load does carry a penalty of increased internal power dissipation. The increased dissipation is understandable considering that the BTL configuration produces 4× the output power of the SE configuration. Internal dissipation versus output power is discussed further in the *crest factor and thermal considerations* section.

single-ended operation

In SE mode (see Figure 5 and Figure 6), the load is driven from the primary amplifier output for each channel (OUT+, terminals 2 and 14).

The amplifier switches single-ended operation when the SE/BTL terminal is held high. This puts the negative outputs in a high-impedance state, and reduces the amplifier's gain to 1 V/V.

BTL amplifier efficiency

Class-AB amplifiers are notoriously inefficient. The primary cause of these inefficiencies is voltage drop across the output stage transistors. There are two components of the internal voltage drop. One is the headroom or dc voltage drop that varies inversely to output power. The second component is due to the sinewave nature of the output. The total voltage drop can be calculated by subtracting the RMS value of the output voltage from V_{DD} . The internal voltage drop multiplied by the RMS value of the supply current, $I_{DD\text{rms}}$, determines the internal power dissipation of the amplifier.

APPLICATION INFORMATION

An easy-to-use equation to calculate efficiency starts out being equal to the ratio of power from the power supply to the power delivered to the load. To accurately calculate the RMS and average values of power in the load and in the amplifier, the current and voltage waveform shapes must first be understood (see Figure 7).

Figure 7. Voltage and Current Waveforms for BTL Amplifiers

Although the voltages and currents for SE and BTL are sinusoidal in the load, currents from the supply are very different between SE and BTL configurations. In an SE application the current waveform is a half-wave rectified shape whereas in BTL it is a full-wave rectified waveform. This means RMS conversion factors are different. Keep in mind that for most of the waveform both the push and pull transistors are not on at the same time, which supports the fact that each amplifier in the BTL device only draws current from the supply for half the waveform. The following equations are the basis for calculating amplifier efficiency.

$$\text{Efficiency of a BTL amplifier} = \frac{P_L}{P_{SUP}} \quad (9)$$

Where:

$$P_L = \frac{V_{L\text{rms}}^2}{R_L}, \text{ and } V_{LRMS} = \frac{V_P}{\sqrt{2}}, \text{ therefore, } P_L = \frac{V_P^2}{2R_L}$$

$$\text{and } P_{SUP} = V_{DD} I_{DD\text{avg}} \quad \text{and} \quad I_{DD\text{avg}} = \frac{1}{\pi} \int_0^\pi \frac{V_P}{R_L} \sin(t) dt = \frac{1}{\pi} \times \frac{V_P}{R_L} [\cos(t)]_0^\pi = \frac{2V_P}{\pi R_L}$$

Therefore,

$$P_{SUP} = \frac{2 V_{DD} V_P}{\pi R_L}$$

substituting P_L and P_{SUP} into equation 9,

$$\text{Efficiency of a BTL amplifier} = \frac{\frac{V_P^2}{2R_L}}{\frac{2 V_{DD} V_P}{\pi R_L}} = \frac{\pi V_P}{4 V_{DD}}$$

Where:

$$V_P = \sqrt{2 P_L R_L}$$

Therefore,

$$\eta_{BTL} = \frac{\pi \sqrt{2 P_L R_L}}{4 V_{DD}}$$

P_L = Power delivered to load
 P_{SUP} = Power drawn from power supply
 V_{LRMS} = RMS voltage on BTL load
 R_L = Load resistance
 V_P = Peak voltage on BTL load
 $I_{DD\text{avg}}$ = Average current drawn from the power supply
 V_{DD} = Power supply voltage
 η_{BTL} = Efficiency of a BTL amplifier

TPA6010A4

STEREO 2-W AUDIO POWER AMPLIFIER WITH BASS BOOST AND DC VOLUME CONTROL

SLOS268 – JUNE 2000

APPLICATION INFORMATION

Table 3 employs equation 10 to calculate efficiencies for four different output power levels. Note that the efficiency of the amplifier is quite low for lower power levels and rises sharply as power to the load is increased, resulting in a nearly flat internal power dissipation over the normal operating range. Note that the internal dissipation at full output power is less than in the half power range. Calculating the efficiency for a specific system is the key to proper power supply design. For a stereo 1-W audio system with 8-Ω loads and a 5-V supply, the maximum draw on the power supply is almost 3.25 W.

Table 3. Efficiency vs Output Power in 5-V 8-Ω BTL Systems

OUTPUT POWER (W)	EFFICIENCY (%)	PEAK VOLTAGE (V)	INTERNAL DISSIPATION (W)
0.25	31.4	2.00	0.55
0.50	44.4	2.83	0.62
1.00	62.8	4.00	0.59
1.25	70.2	4.47 [†]	0.53

[†] High peak voltages cause the THD to increase.

A final point to remember about Class-AB amplifiers (either SE or BTL) is how to manipulate the terms in the efficiency equation to utmost advantage when possible. Note that in equation 10, V_{DD} is in the denominator. This indicates that as V_{DD} goes down, efficiency goes up.

crest factor and thermal considerations

Class-AB power amplifiers dissipate a significant amount of heat in the package under normal operating conditions. A typical music CD requires 12 dB to 15 dB of dynamic range, or headroom above the average power output, to pass the loudest portions of the signal without distortion. In other words, music typically has a crest factor between 12 dB and 15 dB. When determining the optimal ambient operating temperature, the internal dissipated power at the average output power level must be used. From the TPA6010A4 data sheet, one can see that when the TPA6010A4 is operating from a 5-V supply into a 3-Ω speaker that 4-W peaks are available. Converting watts to dB:

$$P_{dB} = 10\text{Log} \frac{P_W}{P_{ref}} = 10\text{Log} \frac{4 \text{ W}}{1 \text{ W}} = 6 \text{ dB} \quad (11)$$

Subtracting the headroom restriction to obtain the average listening level without distortion yields:

- 6 dB – 15 dB = –9 dB (15 dB crest factor)
- 6 dB – 12 dB = –6 dB (12 dB crest factor)
- 6 dB – 9 dB = –3 dB (9 dB crest factor)
- 6 dB – 6 dB = 0 dB (6 dB crest factor)
- 6 dB – 3 dB = 3 dB (3 dB crest factor)

APPLICATION INFORMATION

crest factor and thermal considerations (continued)

Converting dB back into watts:

$$P_W = 10^{P_{dB}/10} \times P_{ref} \quad (12)$$

= 63 mW (18 dB crest factor)
 = 125 mW (15 dB crest factor)
 = 250 mW (9 dB crest factor)
 = 500 mW (6 dB crest factor)
 = 1000 mW (3 dB crest factor)
 = 2000 mW (15 dB crest factor)

This is valuable information to consider when attempting to estimate the heat dissipation requirements for the amplifier system. Comparing the absolute worst case, which is 2 W of continuous power output with a 3 dB crest factor, against 12 dB and 15 dB applications drastically affects maximum ambient temperature ratings for the system. Using the power dissipation curves for a 5-V, 3-Ω system, the internal dissipation in the TPA6010A4 and maximum ambient temperatures is shown in Table 4.

Table 4. TPA6010A4 Power Rating, 5-V, 3-Ω, Stereo

PEAK OUTPUT POWER (W)	AVERAGE OUTPUT POWER	POWER DISSIPATION (W/Channel)	MAXIMUM AMBIENT TEMPERATURE
4	2 W (3 dB)	1.7	–3°C
4	1000 mW (6 dB)	1.6	6°C
4	500 mW (9 dB)	1.4	24°C
4	250 mW (12 dB)	1.1	51°C
4	125 mW (15 dB)	0.8	78°C
4	63 mW (18 dB)	0.6	96°C

Table 5. TPA6010A4 Power Rating, 5-V, 8-Ω, Stereo

PEAK OUTPUT POWER	AVERAGE OUTPUT POWER	POWER DISSIPATION (W/Channel)	MAXIMUM AMBIENT TEMPERATURE
2.5 W	1250 mW (3 dB crest factor)	0.55	100°C
2.5 W	1000 mW (4 dB crest factor)	0.62	94°C
2.5 W	500 mW (7 dB crest factor)	0.59	97°C
2.5 W	250 mW (10 dB crest factor)	0.53	102°C

The maximum dissipated power, $P_{D(max)}$, is reached at a much lower output power level for an 8-Ω load than for a 3-Ω load. As a result, this simple formula for calculating $P_{D(max)}$ may be used for an 8-Ω application:

$$P_{D(max)} = \frac{2V_{DD}^2}{\pi^2 R_L} \quad (13)$$

However, in the case of a 3-Ω load, the $P_{D(max)}$ occurs at a point well above the normal operating power level. The amplifier may therefore be operated at a higher ambient temperature than required by the $P_{D(max)}$ formula for a 3-Ω load.

STEREO 2-W AUDIO POWER AMPLIFIER WITH BASS BOOST AND DC VOLUME CONTROL

SLOS268 – JUNE 2000

APPLICATION INFORMATION

crest factor and thermal considerations (continued)

The maximum ambient temperature depends on the heat sinking ability of the PCB system. The derating factor for the PWP package is shown in the dissipation rating table (see page 4). Converting this to Θ_{JA} :

$$\Theta_{JA} = \frac{1}{\text{Derating Factor}} = \frac{1}{0.022} = 45^{\circ}\text{C/W} \quad (14)$$

To calculate maximum ambient temperatures, first consider that the numbers from the dissipation graphs are per channel so the dissipated power needs to be doubled for two channel operation. Given Θ_{JA} , the maximum allowable junction temperature, and the total internal dissipation, the maximum ambient temperature can be calculated with the following equation. The maximum recommended junction temperature for the TPA6010A4 is 150°C. The internal dissipation figures are taken from the Power Dissipation vs Output Power graphs.

$$\begin{aligned} T_A \text{ Max} &= T_J \text{ Max} - \Theta_{JA} P_D \\ &= 150 - 45(0.6 \times 2) = 96^{\circ}\text{C} \text{ (15 dB crest factor)} \end{aligned} \quad (15)$$

NOTE:

Internal dissipation of 0.6 W is estimated for a 2-W system with 15 dB crest factor per channel.

Tables 4 and 5 show that for some applications no airflow is required to keep junction temperatures in the specified range. The TPA6010A4 is designed with thermal protection that turns the device off when the junction temperature surpasses 150°C to prevent damage to the IC. Table 4 and 5 were calculated for maximum listening volume without distortion. When the output level is reduced the numbers in the table change significantly. Also, using 8- Ω speakers dramatically increases the thermal performance by increasing amplifier efficiency.

SE/BTL operation

The ability of the TPA6010A4 to easily switch between BTL and SE modes is one of its most important cost saving features. This feature eliminates the requirement for an additional headphone amplifier in applications where internal stereo speakers are driven in BTL mode but external headphone or speakers must be accommodated. Internal to the TPA6010A4, two separate amplifiers drive OUT+ and OUT–. The SE/BTL input (terminal 17) controls the operation of the follower amplifier that drives LOUT– and ROUT– (terminals 28 and 16). When SE/BTL is held low, the amplifier is on and the TPA6010A4 is in the BTL mode. When SE/BTL is held high, the OUT– amplifiers are in a high output impedance state, which configures the TPA6010A4 as an SE driver from LOUT+ and ROUT+ (terminals 2 and 14). I_{DD} is reduced by approximately one-half in SE mode. Control of the SE/BTL input can be from a logic-level CMOS source or, more typically, from a resistor divider network as shown in Figure 8.

APPLICATION INFORMATION

SE/BTL operation (continued)

Figure 8. TPA6010A4 Resistor Divider Network Circuit

Using a readily available 1/8-in. (3.5 mm) stereo headphone jack, the control switch is closed when no plug is inserted. When closed the 100-kΩ/1-kΩ divider pulls the SE/BTL input low. When a plug is inserted, the 1-kΩ resistor is disconnected and the SE/BTL input is pulled high. When the input goes high, the OUT– amplifier is shut down causing the speaker to mute (virtually open-circuits the speaker). The OUT+ amplifier then drives through the output capacitor (C_O) into the headphone jack.

PC BEEP operation

The PC BEEP input allows a system beep to be sent directly from a computer through the amplifier to the speakers with few external components. The input is activated automatically. When the PC BEEP input is active, both of the LINEIN and HPIN inputs are deselected and both the left and right channels are driven in BTL mode with the signal from PC BEEP. The gain from the PC BEEP input to the speakers is fixed at 0.3 V/V and is independent of the volume setting. When the PC BEEP input is deselected, the amplifier will return to the previous operating mode and volume setting. Furthermore, if the amplifier is in shutdown mode, activating PC BEEP will take the device out of shutdown and output the PC BEEP signal, then return the amplifier to shutdown mode.

The amplifier will automatically switch to PC BEEP mode after detecting a valid signal at the PC BEEP input. The preferred input signal is a square wave or pulse train with an amplitude of 1 V_{pp} or greater. To be accurately detected, the signal must have a minimum of 1 V_{pp} amplitude, rise and fall times of less than 0.1 μs and a minimum of 8 rising edges. When the signal is no longer detected, the amplifier will return to its previous operating mode and volume setting.

APPLICATION INFORMATION

PC BEEP operation (continued)

If it is desired to ac-couple the PC BEEP input, the value of the coupling capacitor should be chosen to satisfy the following equation:

$$C_{PCB} \geq \frac{1}{2\pi f_{PCB} (100 \text{ k}\Omega)} \quad (16)$$

The PC BEEP input can also be dc-coupled to avoid using this coupling capacitor. The pin normally sits at midrail when no signal is present.

Input MUX operation

Figure 9. TPA6010A4 Example Input MUX Circuit

Another advantage of using the MUX feature is setting the gain of the headphone channel to -1 . This provides the optimum distortion performance into the headphones where clear sound is more important. Refer to the SE/BTL operation section for a description of the headphone jack control circuit.

APPLICATION INFORMATION

shutdown modes

The TPA6010A4 employs a shutdown mode of operation designed to reduce supply current, I_{DD} , to the absolute minimum level during periods of nonuse for battery-power conservation. The $\overline{\text{SHUTDOWN}}$ input terminal should be held high during normal operation when the amplifier is in use. Pulling $\overline{\text{SHUTDOWN}}$ low causes the outputs to mute and the amplifier to enter a low-current state. $\overline{\text{SHUTDOWN}}$ should never be left unconnected because amplifier operation would be unpredictable.

Table 6. Shutdown and Mute Mode Functions

INPUTS [†]		AMPLIFIER STATE	
$\overline{\text{SE/BTL}}$	$\overline{\text{SHUTDOWN}}$	INPUT	OUTPUT
Low	High	Line	BTL
X	Low	X	Mute
High	High	HP	SE

[†] Inputs should never be left unconnected.
 X = do not care
