5-V, LOW-POWER, 12-BIT, 175/360 KSPS, SERIAL ANALOG-TO-DIGITAL CONVERTERS WITH AUTOPOWER DOWN

SLAS276D – MARCH 2000 – REVISED MAY 2003

- Maximum Throughput . . . 175/360 KSPS
- INL/DNL: ± 1 LSB Max, SINAD: 72 dB, SFDR: 85 dB, $f_i = 20$ kHz
- SPI/DSP-Compatible Serial Interface
- Single 5-V Supply
- Rail-to-Rail Analog Input With 500 kHz BW
- Three Options Available:
 - TLC2551: Single Channel Input
 - TLC2552: Dual Channels With Autosweep
 - TLC2555: Single Channel With Pseudo-Differential Input
- Low Power With Autopower Down
 - Operating Current: 3.5 mA
 - Autopower Down: 8 μ A
- Small 8-Pin MSOP and SOIC Packages

description

The TLC2551, TLC2552, and TLC2555 are a family of high performance, 12-bit, low-power, miniature, CMOS analog-to-digital converters (ADC). The TLC255x family uses a 5-V supply. Devices are available with single, dual, or single pseudo-differential inputs. Each device has a chip select (\overline{CS}), serial clock (SCLK), and serial data output (SDO) that provides a direct 3-wire interface to the serial port of most popular host microprocessors (SPI interface). When interfaced with a TMS320™ DSP, a frame sync signal (FS) can be used to indicate the start of a serial data frame on \overline{CS} for all devices or on FS for the TLC2551.

The TLC2551, TLC2552, and TLC2555 are designed to operate with very low power consumption. The power saving feature is further enhanced with an autopower-down mode. This product family features a high-speed serial link to modern host processors with SCLK up to 20 MHz. The maximum SCLK frequency is dependent upon the mode of operation (see Table 1). The TLC255x family uses SCLK as the conversion clock, which provides synchronous operation and a minimum conversion time of 1.5 μ s using a 20-MHz SCLK.

functional block diagram

Terminal Functions

TLC2551

TERMINAL		I/O	DESCRIPTION
NAME	NO.		
AIN	4	I	Analog input channel
$\overline{\text{CS}}$	1	I	Chip select. A high-to-low transition on the $\overline{\text{CS}}$ input removes SDO from 3-state within a maximum setup time. $\overline{\text{CS}}$ can be used as the FS pin when a dedicated DSP serial port is used.
FS	7	I	DSP frame sync input. Indication of the start of a serial data frame. Tie this terminal to V_{DD} if not used.
GND	3	I	Ground return for the internal circuitry. Unless otherwise noted, all voltage measurements are with respect to GND.
SCLK	5	I	Output serial clock. This terminal receives the serial SCLK from the host processor.
SDO	8	O	The 3-state serial output for the A/D conversion result. SDO is kept in the high-impedance state until $\overline{\text{CS}}$ falling edge or FS rising edge, whichever occurs first. The output format is MSB first. When FS is not used ($\text{FS} = 1$ at the falling edge of $\overline{\text{CS}}$), the MSB is presented to the SDO pin after $\overline{\text{CS}}$ falling edge and output data is valid on the first falling edge of SCLK. When $\overline{\text{CS}}$ and FS are both used ($\text{FS} = 0$ at the falling edge of $\overline{\text{CS}}$), the MSB is presented to the SDO pin after the falling edge of $\overline{\text{CS}}$. When $\overline{\text{CS}}$ is tied/held low, the MSB is presented on SDO after rising FS. Output data is valid on the first falling edge of SCLK. (This is typically used with an active FS from a DSP.)
V_{DD}	6	I	Positive supply voltage
V_{REF}	2	I	External reference input

TLC2552/55

TERMINAL		I/O	DESCRIPTION
NAME	NO.		
AIN0 /AIN(+)	4	I	Analog input channel 0 for TLC2552—Positive input for TLC2555
AIN1/AIN(–)	5	I	Analog input channel 1 for TLC2552—Inverted input for TLC2555
$\overline{\text{CS}}$	1	I	Chip select. A high-to-low transition on $\overline{\text{CS}}$ removes SDO from 3-state within a maximum delay time. This pin can be connected to the FS output from a DSP on a dedicated serial port.
GND	3	I	Ground return for the internal circuitry. Unless otherwise noted, all voltage measurements are with respect to GND.
SCLK	7	I	Output serial clock. This terminal receives the serial SCLK from the host processor.
SDO	8	O	The 3-state serial output for the A/D conversion result. SDO is kept in the high-impedance state when $\overline{\text{CS}}$ is high and presents output data after the $\overline{\text{CS}}$ falling edge until the LSB is presented. The output format is MSB first. SDO returns to the Hi-Z state after the 16th SCLK. Output data is valid on the falling SCLK edge.
V_{DD}	6	I	Positive supply voltage
V_{REF}	2	I	External reference input

detailed description

The TLC2551, TLC2552, and TLC2555 are successive approximation (SAR) ADCs utilizing a charge redistribution DAC. Figure 1 shows a simplified version of the ADC.

The sampling capacitor acquires the signal on AIN during the sampling period. When the conversion process starts, the SAR control logic and charge redistribution DAC are used to add and subtract fixed amounts of charge from the sampling capacitor to bring the comparator into a balanced condition. When the comparator is balanced, the conversion is complete and the ADC output code is generated.

detailed description (continued)

Figure 1. Simplified SAR Circuit

serial interface

OUTPUT DATA FORMAT	
MSB	LSB
D15–D4	D3–D0
Conversion result (OD11–OD0)	Don't care

The output data format is binary (unipolar straight binary).

binary

Zero-scale code = 000h, $V_{code} = GND$

Full-scale code = FFFh, $V_{code} = V_{REF} - 1 \text{ LSB}$

pseudo-differential inputs

The TLC2555 operates in pseudo-differential mode. The inverted input is available on pin 5. It can have a maximum input ripple of $\pm 0.2 \text{ V}$. This is normally used for ground noise rejection.

control and timing

start of the cycle

Each cycle may be started by either \overline{CS} , FS, or a combination of both. The internal state machine requires one SCLK high-to-low transition to determine the state of these control signals so internal blocks can be powered up in an active cycle. Special care to SPI mode is necessary. Make sure there is at least one SCLK whenever \overline{CS} (pin 1) is high to assure proper operation.

TLC2551

- Control via \overline{CS} (FS = 1 at the falling edge of \overline{CS})—The falling edge of \overline{CS} is the start of the cycle. The MSB may be read on the first falling SCLK edge after \overline{CS} is low. Output data changes on the rising edge of SCLK. This is typically used for a microcontroller with an SPI interface, although it can also be used for a DSP. The microcontroller SPI interface may be programmed for CPOL = 0 (serial clock referenced to ground) and CPHA = 1 (data is valid on the falling edge of serial clock). At least one falling edge transition on SCLK is needed whenever \overline{CS} is brought high.
- Control via FS—The MSB is presented after the rising edge of FS. The falling edge of FS starts the cycle. The MSB may be read on the first falling edge of SCLK after FS is low. This is the typical configuration when the ADC is the only device on the DSP serial port.

control and timing (continued)

- Control via both \overline{CS} and FS—The MSB is presented after the falling edge of \overline{CS} . The falling edge of FS starts the sampling cycle. The MSB may be read on the first falling SCLK edge after FS is low. Output data changes on the rising edge of SCLK. This control via \overline{CS} and FS is typically used for multiple devices connected to a TMS320 DSP.

TLC2552 and TLC2555

All control is provided using \overline{CS} (pin 1) on the TLC2552 and TLC2555. The cycle starts on the falling edge transition provided by either a \overline{CS} signal from an SPI microcontroller or FS signal from a TMS320 DSP. Timing is similar to the TLC2551, with control via \overline{CS} only.

TLC2552 channel MUX reset cycle

The TLC2552 uses \overline{CS} to reset the analog input multiplexer (MUX). A short active \overline{CS} cycle (4 to 7 SCLKs) resets the MUX to AIN0. When the \overline{CS} cycle time is greater than 7 SCLKs in duration, as is the case for a complete conversion cycle, (\overline{CS} is low for 16 SCLKs plus maximum conversion time), the MUX toggles to the next channel (see Figure 4 for timing).

sampling

The converter sample time is 12 SCLKs in duration, beginning on the fifth SCLK received after the converter has received a high-to-low \overline{CS} transition (or a high-to-low FS transition for the TLC2551).

conversion

The TLC2551, TLC2552, and TLC2555 completes conversion in the following manner. The conversion starts after the 16th SCLK falling edge during the cycle and requires 28 SCLKs to complete. Enough time for conversion should be allowed before a rising \overline{CS} or FS edge so that no conversion is terminated prematurely.

TLC2552 input channel selection is toggled on each rising \overline{CS} edge. The MUX channel can be reset to AIN0 via \overline{CS} as described earlier and in Figure 4. The input is sampled for 12 SCLKs and converted. The result is presented on SDO during the next cycle. Care should also be taken to allow enough time between samples to avoid prematurely terminating the cycle, which occurs on a rising \overline{CS} transition if the conversion is not complete.

The SDO data presented during a cycle is the result of the conversion of the sample taken during the previous cycle.

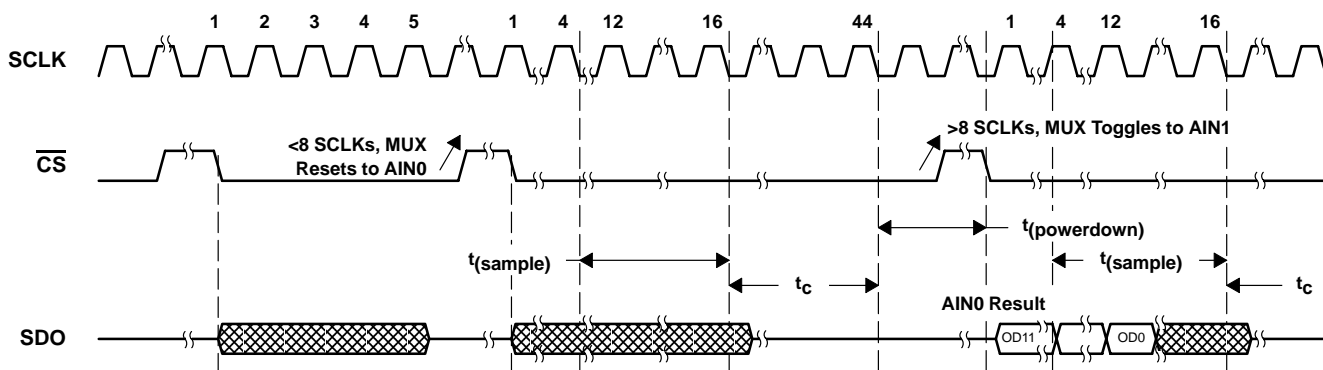

Figure 4. TLC2552 Reset Timing

Figure 5. TLC2552 and TLC2555 Timing

using $\overline{\text{CS}}$ as the FS input

When interfacing the TLC2551 with the TMS320 DSP, the FSR signal from the DSP may be connected to the $\overline{\text{CS}}$ input if this is the only device on the serial port. This connection saves one output terminal from the DSP. (Output data changes on the falling edge of SCLK. This is the default configuration for the TLC2552 and TLC2555).

SCLK and conversion speed

The SCLK input can range in frequency from 100 kHz to 20 MHz. The required number of conversion clocks is 14. The conversion clock for the ADC is SCLK/2 which translates to 28 SCLK cycles to perform a conversion. For a 15-MHz SCLK, the minimum total cycle time is given by: $16 \times (1/15 \text{ M}) + 14 \times (1/7.5 \text{ M}) + 1 \text{ SCLK} = 3.0 \mu\text{s}$. An additional SCLK is added to account for the required $\overline{\text{CS}}$ or FS high time. These times specify the minimum cycle time for an active $\overline{\text{CS}}$ or FS signal. If violated, the conversion terminates, invalidating the next data output cycle. Table 1 gives the maximum SCLK frequency for a given operational mode.

control via pin 1 ($\overline{\text{CS}}$, SPI interface)

All devices are compatible with this mode of operation. A falling $\overline{\text{CS}}$ initiates the cycle. (For TLC2551, the FS input is tied to V_{DD} .) $\overline{\text{CS}}$ remains low for the entire cycle time (sample + convert + 1 SCLK) and can then be released.

NOTE:

IMPORTANT: A single SCLK is required whenever $\overline{\text{CS}}$ is high.

control via pin 1 ($\overline{\text{CS}}$, DSP interface)

All devices are compatible with this mode of operation. The FS signal from a DSP is connected directly to the $\overline{\text{CS}}$ input of the ADC. A falling edge on the $\overline{\text{CS}}$ input initiates the cycle. (For TLC2551, the FS input can be tied to V_{DD} , although better performance can be achieved by using the FS input for control. Refer to the *control via pin 1 and pin 7 ($\overline{\text{CS}}$ and FS or FS only, DSP interface)* section. The $\overline{\text{CS}}$ input should remain low for the entire cycle time (sample + convert + 1 SCLK) and can then be released.

NOTE:

IMPORTANT: A single SCLK is required whenever $\overline{\text{CS}}$ is high. This requirement is usually of little consequence since SCLK is normally always present when interfacing with a DSP.

control via pin 1 and pin 7 ($\overline{\text{CS}}$ and FS or FS only, DSP interface)

Only the TLC2551 is compatible with this mode of operation. The $\overline{\text{CS}}$ input to the ADC can be controlled via a general-purpose I/O pin from the DSP. The FS signal from the DSP is connected directly to the FS input of the ADC. A falling edge on $\overline{\text{CS}}$, if used, releases the MSB on the SDO output. When $\overline{\text{CS}}$ is not used, the rising FS edge releases the MSB. The falling edge on the FS input while SCLK is high initiates the cycle. The $\overline{\text{CS}}$ and FS inputs should remain low for the entire cycle time (sample + convert + 1 SCLK) and can then be released.

reference voltage

An external reference is applied via V_{REF} . The voltage level applied to this pin establishes the upper limit of the analog inputs to produce a full-scale reading. The value of V_{REF} and the analog input must not exceed the positive supply or be less than GND, consistent with the specified absolute maximum ratings. The digital output is at full scale when the input signal is equal to or higher than V_{REF} and at zero when the input signal is equal to or lower than GND.

powerdown and powerup

Autopower down is built into these devices in order to reduce power consumption. The actual power savings depends on the inactive time between cycles and the power supply (loading) decoupling/storage capacitors. *Power-down takes effect immediately after the conversion is complete.* This is fast enough to provide some power savings between cycles with longer than 1 SCLK inactive time. *The device power goes down to 8 μA within 0.5 μs .* To achieve the lowest power-down current (*deep powerdown*) of 1 μA requires 2-ms inactive time between cycles. The power-down state is initiated at the end of conversion. These devices wake up *immediately* at the next falling edge of $\overline{\text{CS}}$ or the rising edge of FS.

IMPORTANT NOTICE

Texas Instruments Incorporated and its subsidiaries (TI) reserve the right to make corrections, modifications, enhancements, improvements, and other changes to its products and services at any time and to discontinue any product or service without notice. Customers should obtain the latest relevant information before placing orders and should verify that such information is current and complete. All products are sold subject to TI's terms and conditions of sale supplied at the time of order acknowledgment.

TI warrants performance of its hardware products to the specifications applicable at the time of sale in accordance with TI's standard warranty. Testing and other quality control techniques are used to the extent TI deems necessary to support this warranty. Except where mandated by government requirements, testing of all parameters of each product is not necessarily performed.

TI assumes no liability for applications assistance or customer product design. Customers are responsible for their products and applications using TI components. To minimize the risks associated with customer products and applications, customers should provide adequate design and operating safeguards.

TI does not warrant or represent that any license, either express or implied, is granted under any TI patent right, copyright, mask work right, or other TI intellectual property right relating to any combination, machine, or process in which TI products or services are used. Information published by TI regarding third-party products or services does not constitute a license from TI to use such products or services or a warranty or endorsement thereof. Use of such information may require a license from a third party under the patents or other intellectual property of the third party, or a license from TI under the patents or other intellectual property of TI.

Reproduction of information in TI data books or data sheets is permissible only if reproduction is without alteration and is accompanied by all associated warranties, conditions, limitations, and notices. Reproduction of this information with alteration is an unfair and deceptive business practice. TI is not responsible or liable for such altered documentation.

Resale of TI products or services with statements different from or beyond the parameters stated by TI for that product or service voids all express and any implied warranties for the associated TI product or service and is an unfair and deceptive business practice. TI is not responsible or liable for any such statements.
