

Precision Picoampere Input Current Quad Operational Amplifier

OP-497

FEATURES

- Low Offset Voltage: 50 μ V max
- Low Offset Voltage Drift: 0.5 μ V/ $^{\circ}$ C max
- Very Low Bias Current
 - +25 $^{\circ}$ C: 100 pA max
 - 55 $^{\circ}$ C to +125 $^{\circ}$ C: 450 pA max
- Very High Open-Loop Gain: 2000 V/mV min
- Low Supply Current (per Amplifier): 625 μ A max
- Operates from \pm 2 V to \pm 20 V Supplies
- High Common-Mode Rejection: 120 dB min

APPLICATIONS

- Strain Gage and Bridge Amplifiers
- High Stability Thermocouple Amplifiers
- Instrumentation Amplifiers
- Photo-Current Monitors
- High-Gain Linearity Amplifiers
- Long-Term Integrators/Filters
- Sample-and-Hold Amplifiers
- Peak Detectors
- Logarithmic Amplifiers
- Battery-Powered Systems

GENERAL DESCRIPTION

The OP-497 is a quad op amp with precision performance in the space saving, industry standard 16-pin SOIC package. Its combination of exceptional precision with low power and extremely low input bias current makes the quad OP-497 useful in a wide variety of applications.

Precision performance of the OP-497 includes very low offset, under 50 μ V, and low drift, below 0.5 μ V/ $^{\circ}$ C. Open-loop gain exceeds 2000 V/mV insuring high linearity in every application. Errors due to common-mode signals are eliminated by the OP-497's common-mode rejection of over 120 dB. The OP-497's power supply rejection of over 120 dB minimizes offset voltage changes experienced in battery powered systems. Supply current of the OP-497 is under 625 μ A per amplifier, and it can operate with supply voltages as low as \pm 2 V.

The OP-497 utilizes a superbeta input stage with bias current cancellation to maintain picoamp bias currents at all temperatures. This is in contrast to FET input op amps whose bias currents start in the picoamp range at 25 $^{\circ}$ C, but double for every 10 $^{\circ}$ C rise in temperature, to reach the nanoamp range above 85 $^{\circ}$ C. Input bias current of the OP-497 is under 100 pA at 25 $^{\circ}$ C and is under 450 pA over the military temperature range.

Combining precision, low power and low bias current, the OP-497 is ideal for a number of applications including instrumentation amplifiers, log amplifiers, photo-diode preamplifiers and long term integrators. For a single device see the OP-97, for a dual see the OP-297.

APPLICATIONS INFORMATION

Extremely low bias current over the full military temperature range makes the OP-497 attractive for use in sample-and-hold amplifiers, peak detectors, and log amplifiers that must operate over a wide temperature range. Balancing input resistances is not necessary with the OP-497. Offset voltage and TCV_{OS} are degraded only minimally by high source resistance, even when unbalanced.

The input pins of the OP-497 are protected against large differential voltage by back-to-back diodes and current-limiting resistors. Common-mode voltages at the inputs are not restricted, and may vary over the full range of the supply voltages used.

The OP-497 requires very little operating headroom about the supply rails, and is specified for operation with supplies as low as ± 2 V. Typically, the common-mode range extends to within one volt of either rail. The output typically swings to within one volt of the rails when using a 10 k Ω load.

AC PERFORMANCE

The OP-497's ac characteristics are highly stable over its full operating temperature range. Unity-gain small-signal response is shown in Figure 27. Extremely tolerant of capacitive loading on the output, the OP-497 displays excellent response even with 1000 pF loads (Figure 28).

Figure 27. Small Signal Transient Response ($C_{LOAD} = 100$ pF, $A_{VCL} = +1$)

Figure 28. Small Signal Transient Response ($C_{LOAD} = 1000$ pF, $A_{VCL} = +1$)

Figure 29. Large Signal Transient Response ($A_{VCL} = +1$)

GUARDING AND SHIELDING

To maintain the extremely high input impedances of the OP-497, care must be taken in circuit board layout and manufacturing. Board surfaces must be kept scrupulously clean and free of moisture. Conformal coating is recommended to provide a humidity barrier. Even a clean PC board can have 100 pA of leakage currents between adjacent traces, so guard rings should be used around the inputs. Guard traces are operated at a voltage close to that on the inputs, as shown in Figure 30, so that leakage currents become minimal. In noninverting applications, the guard ring should be connected to the common-mode voltage at the inverting input. In inverting applications, both inputs remain at ground, so the guard trace should be grounded. Guard traces should be on both sides of the circuit board.

Figure 30. Guard Ring Layout and Connections

OP-497

OPEN-LOOP GAIN LINEARITY

The OP-497 has both an extremely high gain of 2000 V/mv minimum and constant gain linearity. This enhances the precision of the OP-497 and provides for very high accuracy in high closed-loop gain applications. Figure 31 illustrates the typical open-loop gain linearity of the OP-497 over the military temperature range.

Figure 31. Open-Loop Linearity of the OP-497

APPLICATIONS

Precision Absolute Value Amplifier

The circuit of Figure 32 is a precision absolute value amplifier with an input impedance of 30 MΩ. The high gain and low TCV_{OS} of the OP-497 insure accurate operation with microvolt input signals. In this circuit, the input always appears as a common-mode signal to the op amps. The CMR of the OP-497 exceeds 120 dB, yielding an error of less than 2 ppm.

Figure 32. Precision Absolute Value Amplifier

PRECISION CURRENT PUMP

Maximum output current of the precision current pump shown in Figure 33 is $\pm 10\text{ mA}$. Voltage compliance is $\pm 10\text{ V}$ with $\pm 15\text{ V}$ supplies. Output impedance of the current transmitter exceeds 3 MΩ with linearity better than 16 bits.

Figure 33. Precision Current Pump

PRECISION POSITIVE PEAK DETECTOR

In Figure 34, the C_H must be of polystyrene, Teflon*, or polyethylene to minimize dielectric absorption and leakage. The droop rate is determined by the size of C_H and the bias current of the OP-497.

Figure 34. Precision Positive Peak Detector

SIMPLE BRIDGE CONDITIONING AMPLIFIER

Figure 35 shows a simple bridge conditioning amplifier using the OP-497. The transfer function is:

$$V_{OUT} = V_{REF} \left(\frac{\Delta R}{R + \Delta R} \right) \frac{R_F}{R}$$

The REF-43 provides an accurate and stable reference voltage for the bridge. To maintain the highest circuit accuracy, R_F should be 0.1% or better with a low temperature coefficient.

*Teflon is a registered trademark of the Dupont Company.

Figure 35. A Simple Bridge Conditioning Amplifier Using the OP-497

NONLINEAR CIRCUITS

Due to its low input bias currents, the OP-497 is an ideal log amplifier in nonlinear circuits such as the square and square-root circuits shown in Figures 36 and 37. Using the squaring circuit of Figure 36 as an example, the analysis begins by writing a voltage loop equation across transistors Q₁, Q₂, Q₃ and Q₄.

$$V_{T1} \ln \left(\frac{I_{IN}}{I_{S1}} \right) + V_{T2} \ln \left(\frac{I_{IN}}{I_{S2}} \right) = V_{T3} \ln \left(\frac{I_O}{I_{S3}} \right) + V_{T4} \ln \left(\frac{I_{REF}}{I_{S4}} \right)$$

All the transistors of the MAT-04 are precisely matched and at the same temperature, so the I_S and V_T terms cancel, giving:

$$2 \ln I_{IN} = \ln I_O + \ln I_{REF} = \ln (I_O \times I_{REF})$$

Exponentiating both sides of the equation leads to:

$$I_O = \frac{(I_{IN})^2}{I_{REF}}$$

Op amp A₂ forms a current-to-voltage converter which gives V_{OUT} = R₂ × I_O. Substituting (V_{IN}/R₁) for I_{IN} and the above equation for I_O yields:

$$V_{OUT} = \left(\frac{R_2}{I_{REF}} \right) \left(\frac{V_{IN}}{R_1} \right)^2$$

Figure 36. Squaring Amplifier

A similar analysis made for the square-root circuit of Figure 37 leads to its transfer function:

$$V_{OUT} = R_2 \sqrt{\frac{(V_{IN}) (I_{REF})}{R_1}}$$

In these circuits, I_{REF} is a function of the negative power supply. To maintain accuracy, the negative supply should be well regulated. For applications where very high accuracy is required, a voltage reference may be used to set I_{REF}. An important consideration for the squaring circuit is that a sufficiently large input voltage can force the output beyond the operating range of the output op amp. Resistor R₄ can be changed to scale I_{REF}, or R₁ and R₂ can be varied to keep the output voltage within the usable range.

Figure 37. Square Root Amplifier

Unadjusted accuracy of the square-root circuit is better than 0.1% over an input voltage range of 100 mV to 10 V. For a similar input voltage range, the accuracy of the squaring circuit is better than 0.5%.

OP-497

OP-497 SPICE MACRO-MODEL

Figure 38 and Table I show the node and net list for a SPICE macro-model of the OP-497. The model is a simplified version of the actual device and simulates important dc parameters such as V_{OS} , I_{OS} , I_B , A_{VO} , CMR , V_O and I_{SY} . AC parameters such as slew rate, gain and phase response and CMR change with frequency are also simulated by the model.

The model uses typical parameters for the OP-497. The poles and zeros in the model were determined from the actual open and closed-loop gain and phase response of the OP-497. In this way, the model presents an accurate ac representation of the actual device. The model assumes an ambient temperature of 25°C.
