5-V Voltage Regulator

TLE 4287 G

Features

- Output voltage tolerance ≤ ± 2%
- Very low standby current consumption
- Input voltage up to 42 V
- Reset function down to 1 V output voltage
- ESD protection up to 2000 V
- Adjustable reset time
- On/Off logic
- Overtemperature protection
- Reverse polarity protection
- Short-circuit proof
- Very wide temperature range
- Very small output capacitor

Functional Description

The **TLE 4287 G** is a monolithic integrated 5 V voltage regulator in **P-DSO-14-8** package. It supplies an output current I_Q > 250 mA. The IC is short circuit proof and incorporates temperature protection which turns off the device at overtemperature.

The input voltage V_I is regulated in the range of 7.5 V < V_I < 40 V to $V_{Q,nom}$ = 5 V. Therefore a reference voltage, which is kept highly accurate by resistance adjustment, is compared via a control amplifier to a voltage that is proportional to the output voltage. The control amplifier drives the base of the series transistor by a buffer.

A comparator in the reset-generator block compares a reference voltage that is independent of the input voltage to the scaled-down output voltage. In the case of an output voltage V_Q < 4.5 V the reset delay capacitor is discharged and a reset signal is generated by setting the reset output LOW. The reset delay time can be set by choosing the external capacitor over a wide range. When the output voltage rises above V_Q ≥ 4.5 V the reset delay capacitor is charged again. As soon as the delay capacitor voltage reaches the upper switching threshold the reset output pin is set HIGH again.

The device has two logic inputs, *EN* and *H*. It is turned ON by a voltage > 4 V at *EN*, for example by the ignition and remains active in case *H* is set LOW, even if the voltage at *EN* goes LOW. This makes it possible to implement a self-holding circuit without external components. When the device is turned OFF, the output voltage drops to 0 V and current consumption tends towards 0 µA. (Please see following truth table).

Design Notes for External Components

The input capacitor C_I is necessary for compensation line influences. The resonant circuit consisting of lead inductance and input capacitance can be damped by a resistor of approx. 1 Ω in series with C_I. The output capacitor is necessary for the stability of the regulating circuit. Stability is guaranteed for $C_Q \geq 100$ nF within the operating temperature range.

State Table for Turn-On/Turn-Off Logic

Nr.	Enable *EN*	Hold *H*	V_Q	Remarks
1	L	X	0 V	Initial state
2	H	X	5 V	Regulator switched on via pin 6, by ignition for example
3	H	L	5 V	Pin 9 clamped active to GND by controller while pin 6 is still HIGH
4	X	L	5 V	Previous state remains, even ignition is shut off: self-holding state
5	L	L	5 V	Ignition shut off while regulator is in self-holding state
6	L	H	0 V	Regulator shut down by releasing of pin 9 while pin 6 remains LOW, final state. No active clamping required by external self-holding circuit (µC) to keep regulator shut off

Pin Definitions and Functions

Pin No.	Symbol	Function
1	I	**Input**; block to ground directly at the IC by a ceramic capacitor
2	N.C.	Not connected
3, 4, 5, 10, 11, 12, 14	GND	**Ground**
6	EN	**Enable**; active high, device is turned ON by HIGH signal at this pin, internally connected to GND via pull-down resistor of 100 kΩ
7	RO	**Reset Output**; open-collector output, internally connected to Q via a pull-up resistor of 30 kΩ
8	D	**Reset Delay**; connect to GND via external delay capacitor for setting delay time
9	H	**Hold** and release; active low, see truth table above for function, connected to Q via a pull-up resistor of 50 kΩ
13	Q	**Output**; block to GND with a capacitor $C_Q \geq 100$ nF
