32Mb LW R-R HSTL High Speed Synchronous SRAM (2Mb x 18) **Preliminary**

Description

The CXK77K18R320GB is a high speed CMOS synchronous static RAM with common I/O pins, organized as 2,097,152 words by 18 bits. This synchronous SRAMs integrates input registers, high speed RAM, output registers, and a one-deep write buffer onto a single monolithic IC. Register - Register (R-R) read operations and Late Write (LW) write operations are supported, providing a high-performance user interface.

All address and control input signals except $\overline{G}$ (Output Enable) and ZZ (Sleep Mode) are registered on the rising edge of the K differential input clock.

During read operations, output data is driven valid from the rising edge of K, one full clock cycle after the address is registered.

During write operations, input data is registered on the rising edge of K, one full clock cycle after the address is registered.

Sleep (power down) capability is provided via the ZZ input signal.

Output drivers are series terminated, and output impedance is programmable via the ZQ input pin. By connecting an external control resistor RQ between ZQ and V_{SS}, the impedance of the output drivers can be precisely controlled.

333 MHz operation is obtained from a single 1.8V power supply. JTAG boundary scan interface is provided using a subset of IEEE standard 1149.1 protocol.

Notes:

1. "1" = input "high"; "0" = input "low"; "X" = input "don't care".
2. "***" indicates that the input requirement or output state is determined by the previous operation.
3. DQs are tri-stated in response to Write and Deselect commands, one cycle after the command is sampled.

•Sleep (Power Down) Mode

Sleep (power down) mode is provided through the asynchronous input signal ZZ. When ZZ is asserted (high), the output drivers are disabled and the SRAM begins to draw standby current. Contents of the memory array are preserved. An enable time (t_{ZZE}) must be met before the SRAM is guaranteed to be in sleep mode, and a recovery time (t_{ZZR}) must be met before the SRAM can resume normal operation.

•Programmable Impedance Output Drivers

These devices have programmable impedance output drivers. The output impedance is controlled by an external resistor RQ connected between the SRAM's ZQ pin and V_{SS}, and is equal to one-fifth the value of this resistor, nominally. See the DC Electrical Characteristics section for further information.

Output Driver Impedance Power-Up Requirements

Output driver impedance will reach the programmed value within 8192 cycles after power-up. Consequently, it is recommended that Read operations not be initiated until after the initial 8192 cycles have elapsed.

Output Driver Impedance Updates

Output driver impedance is updated during Write and Deselect operations when the output driver is disabled.

•Power-Up Sequence

For reliability purposes, Sony recommends that power supplies power up in the following sequence: V_{SS}, V_{DD}, V_{DDQ}, V_{REF}, and Inputs. V_{DDQ} should never exceed V_{DD}. If this power supply sequence cannot be met, a large bypass diode may be required between V_{DD} and V_{DDQ}. Please contact Sony Memory Application Department for further information.

•Test Mode Description

These devices provide a JTAG Test Access Port (TAP) and Boundary Scan interface using a limited set of IEEE std. 1149.1 functions. This test mode is intended to provide a mechanism for testing the interconnect between master (processor, controller, etc.), SRAMs, other components, and the printed circuit board.

In conformance with a subset of IEEE std. 1149.1, these devices contain a TAP Controller and four TAP Registers. The TAP Registers consist of one Instruction Register and three Data Registers (ID, Bypass, and Boundary Scan Registers).

The TAP consists of the following four signals:

TCK:	Test Clock	Induces (clocks) TAP Controller state transitions.
TMS:	Test Mode Select	Inputs commands to the TAP Controller. Sampled on the rising edge of TCK.
TDI:	Test Data In	Inputs data serially to the TAP Registers. Sampled on the rising edge of TCK.
TDO:	Test Data Out	Outputs data serially from the TAP Registers. Driven from the falling edge of TCK.

Disabling the TAP

When JTAG is not used, TCK should be tied "low" to prevent clocking the SRAM. TMS and TDI should either be tied "high" through a pull-up resistor or left unconnected. TDO should be left unconnected.

Note: Operation of the TAP does not interfere with normal SRAM operation except when the SAMPLE-Z instruction is selected. Consequently, TCK, TMS, and TDI can be controlled any number of ways without adversely affecting the functionality of the device.

TAP Controller

The TAP Controller is a 16-state state machine that controls access to the various TAP Registers and executes the operations associated with each TAP Instruction. State transitions are controlled by TMS and occur on the rising edge of TCK.

The TAP Controller enters the “Test-Logic Reset” state in one of two ways:

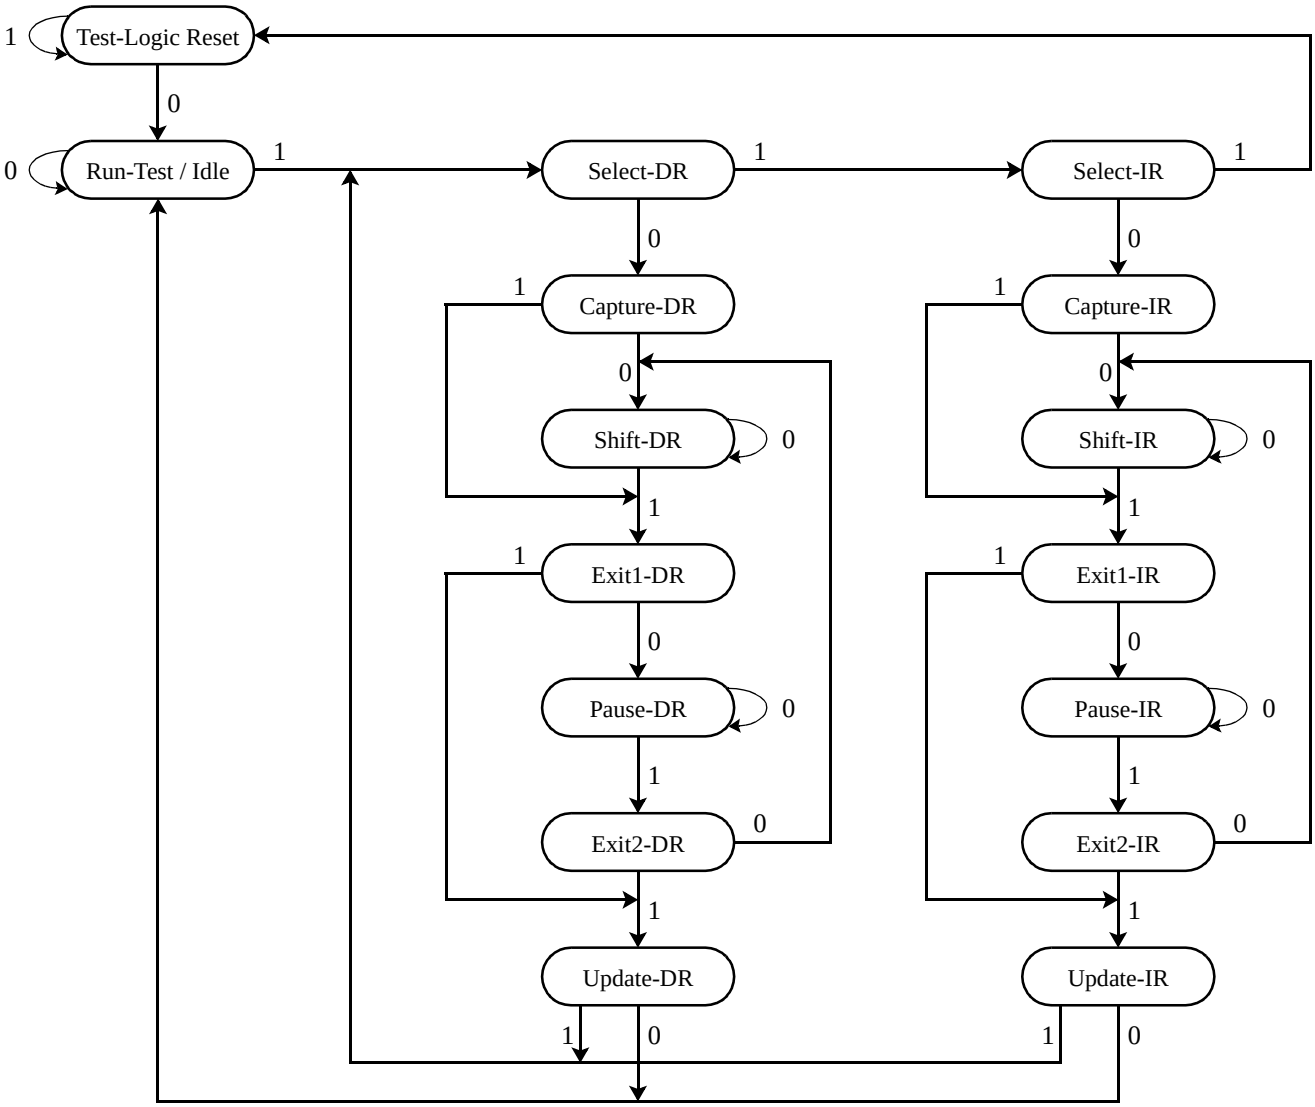
1. At power up.
2. When a logic “1” is applied to TMS for at least 5 consecutive rising edges of TCK.

The TDI input receiver is sampled only when the TAP Controller is in either the “Shift-IR” state or the “Shift-DR” state.

The TDO output driver is active only when the TAP Controller is in either the “Shift-IR” state or the “Shift-DR” state.

TAP Controller State Diagram

Figure 7



TAP Registers

TAP Registers are serial shift registers that capture serial input data (from TDI) on the rising edge of TCK, and drive serial output data (to TDO) from the falling edge of TCK. They are divided into two groups: “Instruction Registers” (IR), which are manipulated via the “IR” states in the TAP Controller, and “Data Registers” (DR), which are manipulated via the “DR” states in the TAP Controller.

Instruction Register (IR - 3 Bits)

The Instruction Register stores the various TAP Instructions supported by these devices. It is loaded with the IDCODE instruction at power-up, and when the TAP Controller is in the “Test-Logic Reset” and “Capture-IR” states. It is inserted between TDI and TDO when the TAP Controller is in the “Shift-IR” state, at which time it can be loaded with a new instruction. However, newly loaded instructions are not executed until the TAP Controller has reached the “Update-IR” state.

The Instruction Register is 3 bits wide, and is encoded as follows:

Code (2:0)	Instruction	Description
000	BYPASS	See code “111”.
001	IDCODE	Loads a predefined device- and manufacturer-specific identification code into the ID Register when the TAP Controller is in the “Capture-DR” state, and inserts the ID Register between TDI and TDO when the TAP Controller is in the “Shift-DR” state. See the ID Register description for more information.
010	SAMPLE-Z	Loads the individual logic states of all signals composing the SRAM’s I/O ring into the Boundary Scan Register when the TAP Controller is in the “Capture-DR” state, and inserts the Boundary Scan Register between TDI and TDO when the TAP Controller is in the “Shift-DR” state. Also disables the SRAM’s data output drivers. See the Boundary Scan Register description for more information.
011	PRIVATE	Do not use. Reserved for manufacturer use only.
100	SAMPLE	Loads the individual logic states of all signals composing the SRAM’s I/O ring into the Boundary Scan Register when the TAP Controller is in the “Capture-DR” state, and inserts the Boundary Scan Register between TDI and TDO when the TAP Controller is in the “Shift-DR” state. See the Boundary Scan Register description for more information.
101	PRIVATE	Do not use. Reserved for manufacturer use only.
110	PRIVATE	Do not use. Reserved for manufacturer use only.
111	BYPASS	Loads a logic “0” into the Bypass Register when the TAP Controller is in the “Capture-DR” state, and inserts the Bypass Register between TDI and TDO when the TAP Controller is in the “Shift-DR” state. See the Bypass Register description for more information.

Bit 0 is the LSB and Bit 2 is the MSB. When the Instruction Register is selected, TDI serially shifts data into the MSB, and the LSB serially shifts data out through TDO.

Bypass Register (DR - 1 Bit)

The Bypass Register is one bit wide, and provides the minimum length serial path between TDI and TDO. It is loaded with a logic "0" when the BYPASS instruction has been loaded in the Instruction Register and the TAP Controller is in the "Capture-DR" state. It is inserted between TDI and TDO when the BYPASS instruction has been loaded into the Instruction Register and the TAP Controller is in the "Shift-DR" state.

ID Register (DR - 32 Bits)

The ID Register is loaded with a predetermined device- and manufacturer-specific identification code when the IDCODE instruction has been loaded into the Instruction Register and the TAP Controller is in the "Capture-DR" state. It is inserted between TDI and TDO when the IDCODE instruction has been loaded into the Instruction Register and the TAP Controller is in the "Shift-DR" state.

The ID Register is 32 bits wide, and contains the following information:

Device	Revision Number (31:28)	Part Number (27:12)	Sony ID (11:1)	Start Bit (0)
2Mb x 18	xxxx	0000 0000 0111 0100	0000 1110 001	1

Bit 0 is the LSB and Bit 31 is the MSB. When the ID Register is selected, TDI serially shifts data into the MSB, and the LSB serially shifts data out through TDO.

Boundary Scan Registers (DR - 51 Bits)

The Boundary Scan Register is equal in length to the number of active signal connections to the SRAM (excluding the TAP pins) plus a number of place holder locations reserved for functional and/or density upgrades. It is loaded with the individual logic states of all signals composing the SRAM's I/O ring when the SAMPLE or SAMPLE-Z instruction has been loaded into the Instruction Register and the TAP Controller is in the "Capture-DR" state. It is inserted between TDI and TDO when the SAMPLE or SAMPLE-Z instruction has been loaded into the Instruction Register and the TAP Controller is in the "Shift-DR" state.

The Boundary Scan Register contains the following bits:

2Mb x 18	
DQ	18
SA	21
K, $\overline{K}$	2
$\overline{SS}$, $\overline{SW}$, $\overline{SBW}$x	4
$\overline{G}$, ZZ	2
ZQ, M1, M2	3
Place Holder	1

Note: K and $\overline{K}$ are connected to a differential input receiver that generates a single-ended input clock signal to the device. Therefore, in order to capture deterministic values for these signals in the Boundary Scan Register, they must be at opposite logic levels when sampled.

Note: When an external resistor RQ is connected between the ZQ pin and V_{SS}, the value of the ZQ signal captured in the Boundary Scan Register is non-deterministic.

Note: Place Holders are required for some NC pins to allow for future density and/or functional upgrades. They are connected to V_{SS} internally, regardless of pin connection externally.

Boundary Scan Register Bit Order Assignments

The tables below depict the order in which the bits are arranged in the Boundary Scan Register. Bit 1 is the LSB and bit 51 is the MSB. When the Boundary Scan Register is selected, TDI serially shifts data into the MSB, and the LSB serially shifts data out through TDO.
