

General Description

MIC2003 and MIC2013 are high-side current limiting devices, designed for power distribution applications in PCs, PDAs, printers and peripheral devices.

MIC2003 and MIC2013 are thermally protected and will shutdown should their internal temperature reach unsafe levels, protecting both the device and the load, under high current or fault conditions. Both devices are fully self-contained, with the current limit value being factory set to one of several convenient levels.

MIC2013 offers a unique new feature: Kickstart™, which allows momentary high current surges to pass unrestricted without sacrificing overall system safety.

MIC2003 and MIC2013 are excellent choices for USB and IEEE 1394 (FireWire) applications or for any system where current limiting and power control are desired.

The MIC2003 and MIC2013 are offered in space saving 6 pin SOT-23 and 2mm x 2mm MLF packages.

Data sheets and support documentation can be found on Micrel's web site at www.micrel.com.

Features

- 70mΩ typical on-resistance
- 2.5V - 5.5V operating range
- Pre-set current limit values of 0.5A, 0.8A and 1.2A
- Kickstart™
- Thermal Protection
- Under voltage lock-out
- Low quiescent current

Applications

- USB / IEEE 1394 Power Distribution
- Desktop and Laptop PCs
- Set top boxes
- Game consoles
- PDAs
- Printers
- Docking stations
- Chargers

Typical Application

Functional Description

Input and Output

V_{IN} is both the power supply connection for the internal circuitry driving the switch and the input (Source connection) of the power MOSFET switch. V_{OUT} is the Drain connection of the power MOSFET and supplies power to the load. In a typical circuit, current flows from V_{IN} to V_{OUT} toward the load. Since the switch is bi-directional when enabled, if V_{OUT} is greater than V_{IN} , current will flow from V_{OUT} to V_{IN} .

When the switch is disabled, current will not flow to the load, except for a small unavoidable leakage current of a few microamps. However, should V_{OUT} exceed V_{IN} by more than a diode drop ($\sim 0.6V$), while the switch is disabled, current will flow from output to input via the power MOSFET's body diode. This effect can be used to advantage when large bypass capacitors are placed on MIC2003/2013's's output. When power to the switch is removed, the output capacitor will be automatically discharged.

If discharging C_{LOAD} is required by your application, consider using MIC2003/2013 or MIC2007/2017 in place of MIC2003/2013. These MIC2000 family members are equipped with a discharge FET to insure complete discharge of C_{LOAD} .

Current Sensing and Limiting

MIC2003/2013 protects the system power supply and load from damage by continuously monitoring current through the on-chip power MOSFET. Load current is monitored by means of a current mirror in parallel with the power MOSFET switch. Current limiting is invoked when the load exceeds an internally set over-current threshold. When current limiting is activated the output current is constrained to the limit value, and remains at this level until either the load/fault is removed, the load's current requirement drops below the limiting value, or the MIC2003/2013 goes into thermal shutdown.

Kickstart (MIC2013 only)

The MIC2013 is designed to allow momentary current surges (Kickstart) before the onset of current limiting, which permits dynamic loads, such as small disk drives or portable printers to draw the energy needed to overcome inertial loads without sacrificing system safety. In this respect, the MIC2013 differs markedly from MIC2003 and its peers, which immediately limit load current, potentially starving the motor and causing the appliance to stall or stutter.

During this delay period, typically 128 ms, a secondary current limit is in effect. If the load demands a current in excess the secondary limit, MIC2013 acts immediately to restrict output current to the secondary limit for the

duration of the Kickstart period. After this time the MIC2013 reverts to its normal current limit. An example of Kickstart operation is shown below.

Figure 3. Kickstart Operation

Picture Key:

- A) MIC2013 is enabled into an excessive load (slew rate limiting not visible at this time scale) The initial current surge is limited by either the overall circuit resistance and power supply compliance, or the secondary current limit, whichever is less.
- B) R_{ON} of the power FET increases due to internal heating (effect exaggerated for emphasis).
- C) Kickstart period.
- D) Current limiting initiated. FAULT/ goes LOW.
- E) V_{OUT} is non-zero (load is heavy, but not a dead short where $V_{OUT} = 0$). Limiting response will be the same for dead shorts).
- F) Thermal shutdown followed by thermal cycling.
- G) Excessive load released, normal load remains. MIC2013 drops out of current limiting.
- H) FAULT/ delay period followed by FAULT/ going HIGH.

Slew Rate Control

Large capacitive loads can create significant current surges when charged through a high-side switch such as the MIC2003/2013. For this reason, MIC2003/2013 provides built-in slew rate control to limit the initial inrush currents upon enabling the power MOSFET switch.

Slew rate control is active upon powering up, and upon re-enabling the load. At shutdown, the discharge slew rate is controlled by the external load and output capacitor.

Thermal Shutdown

Thermal shutdown is employed to protect MIC2003/2013 from damage should the die temperature exceed safe operating levels. Thermal shutdown shuts off the output MOSFET and asserts the FAULT/ output if the die temperature reaches 145°C.

MIC2003/2013 will automatically resume operation when the die temperature cools down to 135°C. If resumed operation results in reheating of the die, another shutdown cycle will occur and the

MIC2003/2013 will continue cycling between ON and OFF states until the offending load has been removed.

Depending on PCB layout, package type, ambient temperature, etc., hundreds of milliseconds may elapse from the incidence of a fault to the output MOSFET being shut off. This delay is due to thermal time constants within the system itself. In no event will the device be damaged due to thermal overload because die temperature is monitored continuously by on-chip circuitry.

Application Information

I_{LIMIT} vs. I_{OUT} measured

MIC2003/2013's current limiting circuitry is designed to act as a constant current source to the load. As the load tries to pull more than the allotted current, V_{OUT} drops and the input to output voltage differential increases. When $V_{IN} - V_{OUT}$ exceeds 1V, I_{OUT} drops below I_{LIMIT} to reduce the drain of fault current on the system's power supply and to limit internal heating of MIC2003/2013.

When measuring I_{OUT} it is important to bear this voltage dependence in mind, otherwise the measurement data may appear to indicate a problem when none really exists. This voltage dependence is illustrated in Figures 4 and 5.

In Figure 4 output current is measured as V_{OUT} is pulled below V_{IN} , with the test terminating when V_{OUT} is 1V below V_{IN} . Observe that once I_{LIMIT} is reached I_{OUT} remains constant throughout the remainder of the test. In Figure 5 this test is repeated but with $V_{IN} - V_{OUT}$ exceeding 1V.

When $V_{IN} - V_{OUT} > 1V$, MIC2003/2013's current limiting circuitry responds by decreasing I_{OUT} , as can be seen in Figure 5. In this demonstration, V_{OUT} is being controlled and I_{OUT} is the measured quantity. In real life applications V_{OUT} is determined in accordance with Ohm's law by the load and the limiting current.

2009B SOT 502 #1 - Current ramp [5V]

 A1: Vout (2V/div)
 A2: Iout (500mA/div)

Figure 5. I_{OUT} in Current Limiting for $V_{OUT} > 1V$

This folding back of I_{LIMIT} can be generalized by plotting I_{LIMIT} as a function of V_{OUT} , as shown below. The slope of V_{OUT} between $I_{OUT} = 0$ and $I_{OUT} = I_{LIMIT}$ (where $I_{LIMIT} = 1$) is determined by R_{ON} of MIC2003/2013 and I_{LIMIT} .

Figure 6.

Figure 7.

Kickstart (MIC2013)

Kickstart allows brief current surges to pass to the load before the onset of normal current limiting, which permits dynamic loads to draw bursts of energy without sacrificing system safety.

Functionally, Kickstart is a forced override of the normal current limiting function provided by MIC2013. The Kickstart period is governed by an internal timer which allows current to pass unimpeded to the load for 128ms and then normal (primary) current limiting goes into action.

During Kickstart a secondary current limiting circuit is monitoring output current to prevent damage to the MIC2013, as a hard short combined with a robust power supply can result in currents of many tens of amperes. This secondary current limit is nominally set at 4 Amps and reacts immediately and independently of the Kickstart period. Once the Kickstart timer has finished its count the primary current limiting circuit takes over and holds I_{OUT} to its programmed limit for as long as the excessive load persists.

Once MIC2013 drops out of current limiting the Kickstart timer initiates a lock-out period of 128ms such that no further bursts of current above the primary current limit, will be allowed until the lock-out period has expired.

Kickstart may be over-riden by the thermal protection circuit and if sufficient internal heating occurs, Kickstart will be terminated and I_{OUT} → 0. Upon cooling, if the load is still present I_{OUT} → I_{LIMIT}, not I_{KICKSTART}.

Figure 9. Kickstart

Supply Filtering

A 0.1µF to 1µF bypass capacitor positioned close to the V_{IN} and GND pins of MIC2003/2013 is both good design practice and required for proper operation of MIC2003/2013. This will control supply transients and ringing. Without a bypass capacitor, large current surges or an output short may cause sufficient ringing on V_{IN} (from supply lead inductance) to cause erratic operation of MIC2003/2013's control circuitry. Good quality, low ESR capacitors, such as Panasonic's TE or ECJ series, are suggested.

When bypassing with capacitors of 10µF and up, it is good practice to place a smaller value capacitor in parallel with the larger to handle the high frequency components of any line transients. Values in the range of 0.01µF to 0.1µF are recommended. Again, good quality, low ESR capacitors should be chosen.

Power Dissipation

Power dissipation depends on several factors such as the load, PCB layout, ambient temperature, and supply voltage. Calculation of power dissipation can be accomplished by the following equation:

$$P_D = R_{DS(ON)} \times (I_{OUT})^2$$

To relate this to junction temperature, the following equation can be used:

$$T_J = P_D \times R_{\theta(J-A)} + T_A$$

Where: T_J = junction temperature,

T_A = ambient temperature

$R_{\theta(J-A)}$ is the thermal resistance of the package

In normal operation MIC2003/2013's R_{on} is low enough that no significant I^2R heating occurs. Device heating is most often caused by a short circuit, or very heavy load, when a significant portion of the input supply voltage appears across MIC2003/2013's power MOSFET. Under these conditions the heat generated will exceed the package and PCB's ability to cool the device and thermal limiting will be invoked.

In Figure 10 die temperature is plotted against I_{OUT} assuming a constant case temperature of 85°C. The plots also assume a worst case R_{ON} of 140 mΩ at a die temperature of 135°C. Under these conditions it is clear that an SOT-23 packaged device will be on the verge of thermal shutdown, typically 140°C die temperature, when operating at a load current of 1.25A. For this reason we recommend using MLF packaged MIC2003/2013s for any design intending to supply continuous currents of 1A or more.

When operating at higher current levels or in higher temperature environments use of Micrel's MLF packaging is recommended. MLF packages provide an exposed power paddle on the back side to which electrical and thermal contact can be made with the device. This significantly reduces the package's thermal resistance and thus extends the MIC2005/2013's operating range.
