

## 2W Stereo Audio Amplifier

### Features

- Internal Gain Control, Which Eliminates External Gain-Setting Resistors
- Depop Circuitry Integrated
- Output Power at 1% THD+N, VDD=5V  
--2.0W/CH (typical) into a 4Ω Load  
--1.2W/CH (typical) into a 8Ω Load
- Bridge-Tied Load (BTL) Supported
- Fully differential Input
- Shutdown Control Available
- Surface-Mount Power Package  
20-Pin TSSOP-P & 20-Pin TQFN 4X4

### Applications

- Stereo Power Amplifiers for Notebooks or Desktop Computers
- Multimedia Monitors
- Stereo Power Amplifiers for Portable Audio Systems

### General Description

G1431 is a stereo audio power amplifier in 20pin TSSOP thermal pad package or 20-pin TQFN 4X4. It can drive 2W continuous RMS power into 4Ω load per channel in Bridge-Tied Load (BTL) mode at 5V supply voltage. Its THD is smaller than 1% under the above operation condition. To simplify the audio system design in the notebook application and to enlarge the driving power, G1431 supports the Bridge-Tied Load (BTL) mode for driving the speakers. For the low current consumption applications, the SHDN mode is supported to disable G1431 when it is idle. The current consumption can be reduced to 150μA (typically).

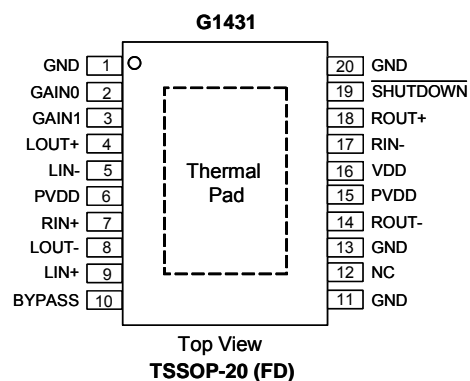

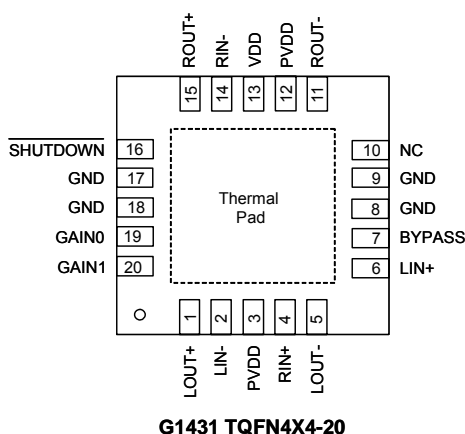

Amplifier gain is internally configured and controlled by two terminals (GAIN0, GAIN1). BTL gain settings of 6dB, 10dB, 15.6dB, 21.6dB are provided.

### Ordering Information

ORDER NUMBER	MARKING	TEMP. RANGE	PACKAGE (Pb free)
G1431F2U	G1431	-40°C to +85°C	TSSOP-20 (FD)
G1431R9U	1431	-40°C to +85°C	TQFN4X4-20

Note: F2: TSSOP-20 (FD) R9:TQFN4X4-20  
U: Tape & Reel

### Pin Configuration

## Absolute Maximum Ratings

Supply Voltage, $V_{CC}$ . . . . .	.6V	Power Dissipation <sup>(1)</sup>	
Operating Ambient Temperature Range		$T_A \leq 25^\circ\text{C}$ . . . . .	2.7W
$T_A$ . . . . .	-40°C to +85°C	$T_A \leq 70^\circ\text{C}$ . . . . .	1.7W
Maximum Junction Temperature, $T_J$ . . . . .	150°C	Electrostatic Discharge, $V_{ESD}$	
Storage Temperature Range, $T_{STG}$ . . . . .	-65°C to +150°C	Human body mode . . . . .	3000V <sup>(2)</sup>
Reflow Temperature (soldering, 10sec) . . . . .	.260°C		

**Note:**

<sup>(1)</sup>: Recommended PCB Layout

<sup>(2)</sup>: Human body model : C = 100pF, R = 1500Ω, 3 positive pulses plus 3 negative pulses

## Electrical Characteristics

### DC Electrical Characteristics, $T_A=+25^\circ\text{C}$

## Pin Description

PIN		NAME	I/O	FUNCTION
TSSOP-20(FD)	TQFN4X4-20			
1,11,13,20	8,9,17,18	GND/HS		Ground connection for circuitry, directly connected to thermal pad.
2	19	GAIN0	I	Bit 0 of gain control
3	20	GAIN1	I	Bit 1 of gain control
4	1	LOUT+	O	Left channel + output in BTL mode
5	2	LIN-	I	Negative left input for fully differential inputs.
6,15	3,12	PVDD		Power supply for output stages.
7	4	RIN+	I	Positive right input for fully differential inputs. AC ground for single-ended inputs.
8	5	LOUT-	O	Left channel - output in BTL mode
9	6	LIN+	I	Positive left input for fully differential inputs. AC ground for single-ended inputs.
10	7	BYPASS		Tap to voltage divider for internal mid-supply bias generator.
12	10	NC		NC
14	11	ROUT-	O	Right channel - output in BTL mode
16	13	VDD		Analog VDD input supply. This terminal needs to be isolated from PVDD to achieve highest performance.
17	14	RIN-	I	Negative right input for fully differential inputs.
18	15	ROUT+	O	Right channel + output in BTL mode
19	16	SHUTDOWN	I	Places entire IC in shutdown mode when held low

**Typical G1431 Application Circuit Using Single-Ended Inputs**

Application Circuit (continued)

Typical G1431 Application Circuit Using Differential Inputs

**Application Information**

**Gain setting via GAIN0 and GAIN1 inputs**

The internal gain setting is determined by two input terminals, GAIN0 and GAIN1. The gains listed in Table 1 are realized by changing the taps on the input resistors inside the amplifier. This will cause the internal input impedance,  $Z_i$ , to be dependent on the gain setting. Although the real input impedance will shift by 30% due to process variation from part-to-part, the actual gain settings are controlled by the ratios of the resistors and the actual gain distribution from part-to-part is quite good.

**Table 1**

GAIN0	GAIN1	$A_v$ (dB)
0	0	6
0	1	10
1	0	15.6
1	1	21.6

**Input Resistance**

The typical input impedance at each gain setting is given in the Table 2. Each gain setting is achieved by varying the input resistance of the amplifier, which can be over 6 times from its minimum value to the maximum value. As a result, if a single capacitor is used in the input high pass filter, the  $-3$ dB or cut-off frequency will be also change over 3.5 times. To reduce the variation of the cut-off frequency, an additional resistor can be connected from the input pin of the amplifier to the ground, as shown in the figure below. With the extra resistor, the cut-off frequency can be re-calculated using equation :  $f_{-3dB} = 1 / 2\pi C(R||R_i)$ . Using small external R can reduce the variation of the cut-off frequency. But the side effect is small external R will also let  $(R||R_i)$  become small, the cut-off frequency will be larger and degraded the bass-band performance. The other side effect is with extra power dissipation through the external resistor R to the ground. So using the external resistor R to flattening the variation of the cut-off frequency, the user must also consider the bass-band performance and the extra power dissipation to choose the accepted external resistor R value.

**Table 2**

$Z_i$ (k $\Omega$ )	$A_v$ (dB)
30	21.6
45	15.6
70	10
90	6

**Input Capacitor**

In the typical application, an input capacitor  $C_i$  is required to allow the amplifier to bias the input signal to the proper dc level for optimum operation. In this case,  $C_i$  and the input impedance of the amplifier,  $Z_i$ , form a high-pass filter with the  $-3$ dB determined by the equation:  $f_{-3dB} = 1 / 2\pi R_i C_i$

The value of  $C_i$  is important to consider as it directly affects the bass performance of the application circuit. For example, if the input resistor is  $15k\Omega$ , the input capacitor is  $1\mu F$ , the flat bass response will be down to  $10.6$ Hz.

Because the small leakage current of the input capacitors will cause the dc offset voltage at the input to the amplifier that reduces the operation headroom, especially at the high gain applications. The low-leakage tantalum or ceramic capacitors are suggested to be used as the input coupling capacitors. When using the polarized capacitors, it is important to let the positive side connecting to the higher dc level of the application.

**Power Supply Decoupling**

The G1431 is a high-performance CMOS audio amplifier that requires adequate power supply decoupling to make sure the output total harmonic distortion (THD) as low as possible. The optimum decoupling is using two capacitors with different types that target different types of noise on the power supply leads. For high frequency transients, spikes, a good low ESR ceramic capacitor works best, typically  $0.1\mu F/1\mu F$  used and placed as close as possible to the G1431 VDD lead. A larger aluminum electrolytic capacitor of  $10\mu F$  or greater placed near the device power is recommended for filtering low-frequency noise.

**Optimizing DEPOP Operation**

Circuitry has been implemented in G1431 to minimize the amount of popping heard at power-up and when coming out of shutdown mode. Popping occurs whenever a voltage step is applied to the speaker and making the differential voltage generated at the two ends of the speaker. To avoid the popping heard, the bypass capacitor should be chosen promptly,  $1/(C_B \times 170k\Omega) \leq 1/(C_i \times (R_i + R_F))$ . Where  $170k\Omega$  is the output impedance of the mid-rail generator,  $C_B$  is the mid-rail bypass capacitor,  $C_i$  is the input coupling capacitor,  $R_i$  is the input impedance,  $R_F$  is the gain set-

ting impedance which is on the feedback path.  $C_B$  is the most important capacitor. Besides it is used to reduce the popping,  $C_B$  can also determine the rate at which the amplifier starts up during startup or recovery from shutdown mode.

De-popping circuitry of G1431 is shown as below Figure 1. The PNP transistor limits the voltage drop across the  $120k\Omega$  by slewing the internal node slowly when power is applied. At start-up, the voltage at BYPASS capacitor is 0. The PNP is ON to pull the mid-point of the bias circuit down. So the capacitor sees a lower effective voltage, and thus the charging is slower. This appears as a linear ramp (while the PNP transistor is conducting), followed by the expected exponential ramp of an R-C circuit.

For better performance,  $C_B$  is recommended to be at least 1.5 times of input coupling capacitor  $C_I$ . For example, if using  $1\mu F$  input coupling capacitor,  $2.2\mu F$  ceramic or tantalum low-ESR capacitors are recommended to achieve the better THD performance.

**Figure 1**

**Bridged-Tied Load Mode Operation**

G1431 has two linear amplifiers to drive both ends of the speaker load in Bridged-Tied Load (BTL) mode operation. Figure 2 shows the BTL configuration. The differential driving to the speaker load means that when one side is slewing up, the other side is slewing down, and vice versa. This configuration in effect will double the voltage swing on the load as compared to a ground reference load. In BTL mode, the peak-to-peak

voltage  $V_o(PP)$  on the load will be two times than a ground reference configuration. The voltage on the load is doubled, this will also yield 4 times output power on the load at the same power supply rail and loading. Another benefit of using differential driving configuration is that BTL operation cancels the dc offsets, which eliminates the dc coupling capacitor that is needed to cancelled dc offsets in the ground reference configuration. Low-frequency performance is then limited only by the input network and speaker responses. Cost and PCB space can be minimized by eliminating the dc coupling capacitors.

**Figure 2**

**Shutdown mode**

When the normal operation, the SHUTDOWN pin should be held high. Pulling SHUTDOWN low will mute the outputs and deactivate the most of the circuits. At this moment, the current of this device will be reduced to about  $160\mu A$  to save the battery energy. The SHUTDOWN pin should never be left unconnected during the normal applications.

INPUT *	AMPLIFIER STATE
SHUTDOWN	OUTPUT
Low	Mute
High	BTL
* Inputs should never be left unconnected	
X= do not care	

## Package Information

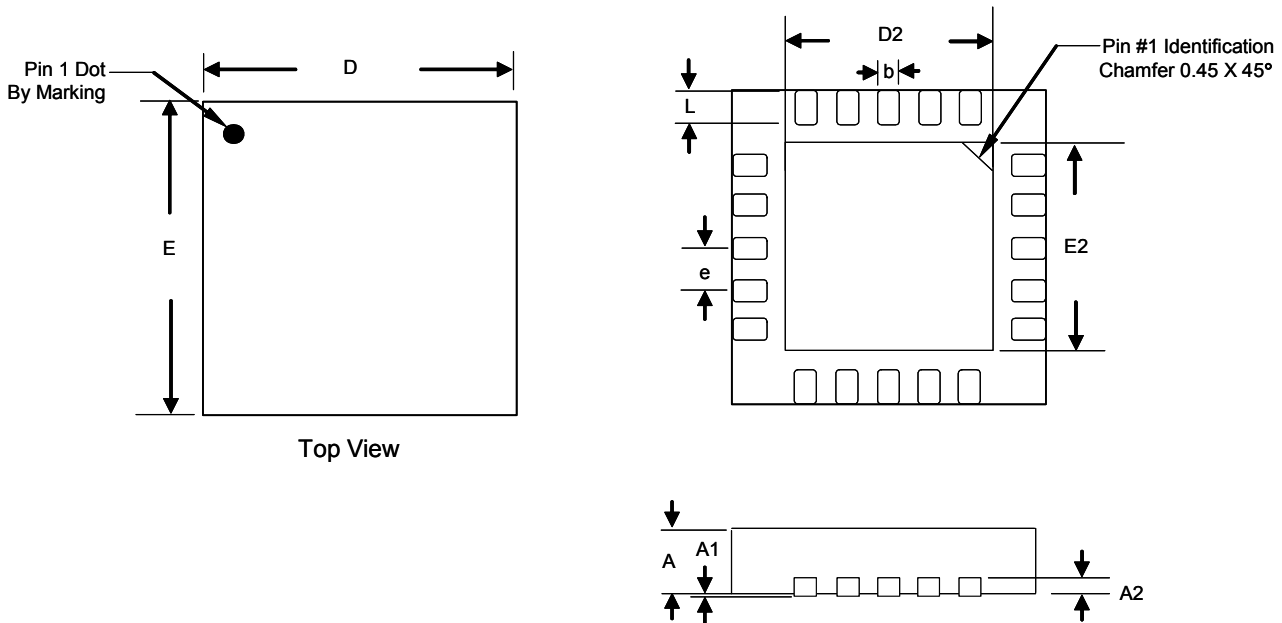

**TSSOP-20 (FD) Package**

**Note:**

1. JEDCE outline: MP-153 AC/MO-153 ACT (thermally enhanced variations only)
2. Dimension "D" does not include mold flash, protrusions or gate burrs. Mold flash, protrusions or gate burrs shall not exceed 0.15 per side.
3. Dimension "E1" does not include interlead flash or protrusion. Interlead flash or protrusion shall not exceed 0.25 per side.
4. Dimension "b" does not include dambar protrusion. Allowable dambar protrusion shall be 0.08mm total in excess of the "b" dimension at maximum material conditions. Dambar cannot be located on the lower radius of the foot. Minimum space between protrusion and adjacent lead is 0.07mm.
5. Dimensions "D" and "E1" to be determined at datum plane "H".
