

To all our customers

Regarding the change of names mentioned in the document, such as Mitsubishi Electric and Mitsubishi XX, to Renesas Technology Corp.

The semiconductor operations of Hitachi and Mitsubishi Electric were transferred to Renesas Technology Corporation on April 1st 2003. These operations include microcomputer, logic, analog and discrete devices, and memory chips other than DRAMs (flash memory, SRAMs etc.) Accordingly, although Mitsubishi Electric, Mitsubishi Electric Corporation, Mitsubishi Semiconductors, and other Mitsubishi brand names are mentioned in the document, these names have in fact all been changed to Renesas Technology Corp. Thank you for your understanding. Except for our corporate trademark, logo and corporate statement, no changes whatsoever have been made to the contents of the document, and these changes do not constitute any alteration to the contents of the document itself.

Note : Mitsubishi Electric will continue the business operations of high frequency & optical devices and power devices.

User's Manual

EOL announced

keep safety first in your circuit designs !

- Mitsubishi Electric Corporation puts the maximum effort into making semiconductor products better and more reliable, but there is always the possibility that trouble may occur with them. Trouble with semiconductors may lead to personal injury, fire or property damage. Remember to give due consideration to safety when making your circuit designs, with appropriate measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of non-flammable material or (iii) prevention against any malfunction or mishap.

Notes regarding these materials

- These materials are intended as a reference to assist our customers in the selection of the Mitsubishi semiconductor product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Mitsubishi Electric Corporation or a third party.
- Mitsubishi Electric Corporation assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts or circuit application examples contained in these materials.
- All information contained in these materials, including product data, diagrams and charts, represent information on products at the time of publication of these materials, and are subject to change by Mitsubishi Electric Corporation without notice due to product improvements or other reasons. It is therefore recommended that customers contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor for the latest product information before purchasing a product listed herein.
- Mitsubishi Electric Corporation semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
- The prior written approval of Mitsubishi Electric Corporation is necessary to reprint or reproduce in whole or in part these materials.
- If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination. Any diversion or reexport contrary to the export control laws and regulations of JAPAN and/or the country of destination is prohibited.
- Please contact Mitsubishi Electric Corporation or an authorized Mitsubishi Semiconductor product distributor for further details on these materials or the products contained therein.

REVISION DESCRIPTION LIST

7721 Group User's Manual

Rev. No.	Revision Description	Rev. date
1.0	First Edition	970926
<p>EOL announced</p>		

Preface

This manual describes the hardware of the Mitsubishi CMOS 16-bit microcomputers 7721 Group. After reading this manual, the user will be able to understand the functions, so that their capabilities can fully be utilized.

EOL announced

BEFORE USING THIS MANUAL

1. Constitution

This user's manual consists of the following chapters. Refer to the chapters relevant to the products.

- **Chapter 1. DESCRIPTION through Chapter 16. APPLICATION**

Functions which are common to the M37721S1BFP and the M37721S2BFP are explained, using the M37721S2BFP as an example.

Differences between the M37721S1BFP and the M37721S2BFP are described as notes.

- **Appendix**

Practical information for using the 7721 Group is described.

2. Remark

- **Product expansion**

Refer to the latest catalog and data book, or contact the appropriate office, as listed in "CONTACT ADDRESSES FOR FURTHER INFORMATION" on the last page.

- **Electrical characteristics**

Refer to the latest data book.

- **Software**

Refer to "7700 Family Software Manual."

- **Development support tools**

Refer to the latest data book of the development support tools.

3. Signal levels in Figure

As a rule, signal levels in each operation example and timing diagram are as follows.

- **Signal levels**

The upper line indicates "1," and the lower line indicates "0."

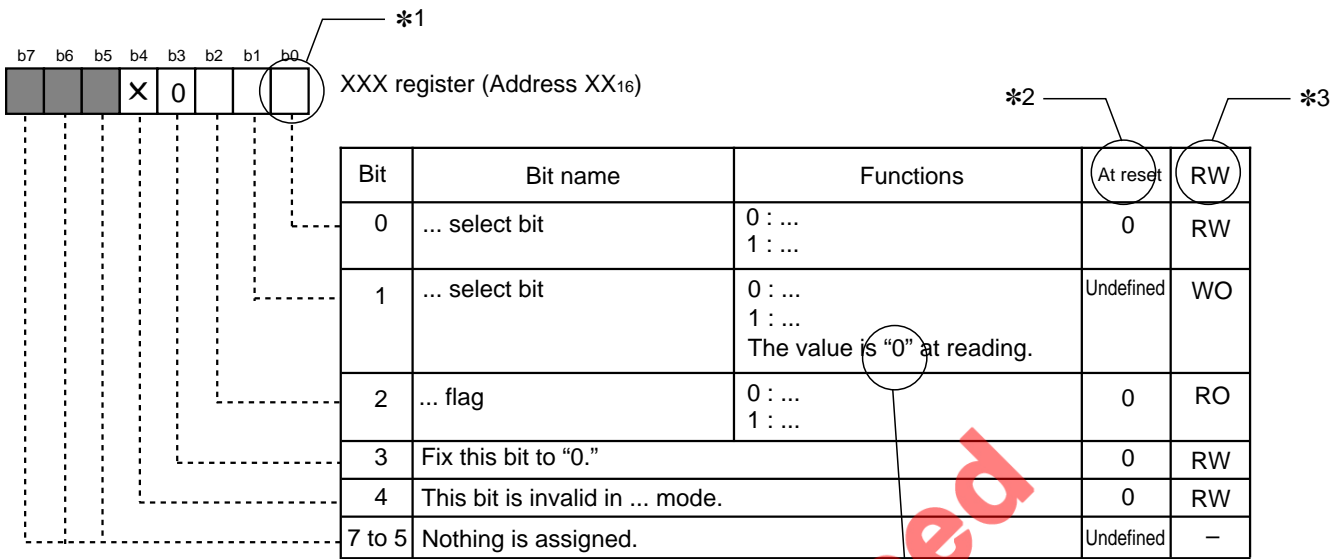

- **Input/output levels of pin**

The upper line indicates "H," and the lower line indicates "L."

For the exception, the level is shown on the left side of a signal.

4. Register structure

Below is the structure diagram for all registers:

*1

- Blank : Set to "0" or "1" according to the usage.
- 0 : Set to "0" at writing.
- 1 : Set to "1" at writing.
- X : Invalid depending on the mode or state. It may be "0" or "1."
- : Nothing is assigned.

*2

- 0 : "0" immediately after reset.
- 1 : "1" immediately after reset.
- Undefined : Undefined immediately after reset.

*3

- RW : It is possible to read the bit state at reading. The written value becomes valid.
- RO : It is possible to read the bit state at reading. The written value becomes invalid. Accordingly, the written value may be "0" or "1."
- WO : The written value becomes valid. It is impossible to read the bit state. The value is undefined at reading. However, when ["0" at reading] is indicated in the "Function" or "Note" column, the bit is always "0" at reading. (See *4 above.)
- : It is impossible to read the bit state. The value is undefined at reading. However, when ["0" at reading] is indicated in the "Function" or "Note" column, the bit is always "0" at reading. (See *4 above.)
The written value becomes invalid. Accordingly, the written value may be "0" or "1."

Table of contents

CHAPTER 1 DESCRIPTION

1.1 Performance overview.....	1-2
1.2 Pin configuration.....	1-3
1.3 Pin description	1-4
1.4 Block diagram	1-7

CHAPTER 2 CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit	2-2
2.1.1 Accumulator (Acc)	2-3
2.1.2 Index register X (X).....	2-3
2.1.3 Index register Y (Y).....	2-3
2.1.4 Stack pointer (S).....	2-4
2.1.5 Program counter (PC)	2-5
2.1.6 Program bank register (PG)	2-5
2.1.7 Data bank register (DT)	2-5
2.1.8 Direct page register (DPR).....	2-6
2.1.9 Processor status register (PS).....	2-7
2.2 Bus interface unit	2-9
2.2.1 Overview	2-9
2.2.2 Functions of bus interface unit (BIU)	2-11
2.2.3 Operation of bus interface unit (BIU).....	2-13
2.3 Access space	2-15
2.3.1 Banks	2-16
2.3.2 Direct page	2-16
2.4 Memory assignment	2-17
2.4.1 Memory assignment in internal area.....	2-17
2.4.2 External area	2-18
2.5 Bus access right	2-23

CHAPTER 3 CONNECTION WITH EXTERNAL DEVICES

3.1 Signals required for accessing external devices	3-2
3.1.1 Descriptions of signals	3-2
3.1.2 Operation of bus interface unit (BIU).....	3-5
3.2 Software Wait.....	3-8
3.3 Ready function	3-10
3.3.1 Operation description	3-11
3.4 Hold function	3-12
3.4.1 Operation description	3-12
[Precautions for Hold function]	3-16

Table of contents

CHAPTER 4 RESET

4.1 Hardware reset	4-2
4.1.1 Pin state	4-3
4.1.2 State of CPU, SFR area, and internal RAM area	4-4
4.1.3 Internal processing sequence after reset	4-11
4.1.4 Time supplying “L” level to RESET pin	4-12
4.2 Software reset	4-13

CHAPTER 5 CLOCK GENERATING CIRCUIT

5.1 Oscillation circuit examples	5-2
5.1.1 Connection example using resonator/oscillator	5-2
5.1.2 Externally generated clock input example	5-2
5.2 Clocks	5-3
5.2.1 Clocks generated in clock generating circuit	5-4
5.3 Stop mode	5-5
5.3.1 Stop mode	5-5
[Precautions for Stop mode]	5-8
5.4 Wait mode	5-9
5.4.1 Wait mode	5-9
[Precautions for Wait mode]	5-11

CHAPTER 6 INPUT/OUTPUT PINS

6.1 Overview	6-2
6.2 Programmable I/O ports	6-2
6.2.1 Direction register	6-3
6.2.2 Port register	6-4
6.3 Examples of handling unused pins	6-7

CHAPTER 7 INTERRUPTS

7.1 Overview	7-2
7.2 Interrupt sources	7-4
7.3 Interrupt control	7-5
7.3.1 Interrupt disable flag (I)	7-7
7.3.2 Interrupt request bit	7-7
7.3.3 Interrupt priority level select bits and processor interrupt priority level (IPL)	7-7
7.4 Interrupt priority level	7-9
7.5 Interrupt priority level detection circuit	7-10
7.6 Interrupt priority level detection time	7-12
7.7 Sequence from acceptance of interrupt request until execution of interrupt routine	7-13
7.7.1 Change in IPL at acceptance of interrupt request	7-14
7.7.2 Push operation for registers	7-15
7.8 Return from interrupt routine	7-16
7.9 Multiple interrupts	7-16
7.10 External interrupts (INT_i interrupt)	7-18
7.10.1 Functions of INT _i interrupt request bit	7-20
7.10.2 Switching of INT _i interrupt request occurrence factor	7-21
7.11 Precautions for interrupts	7-22

CHAPTER 8 TIMER A

8.1 Overview	8-2
8.2 Block description	8-3
8.2.1 Counter and reload register (timer Ai register)	8-4
8.2.2 Count start register	8-5
8.2.3 Timer Ai mode register	8-6
8.2.4 Timer Ai interrupt control register	8-7
8.2.5 Port P5 direction register	8-8
8.3 Timer mode	8-9
8.3.1 Setting for timer mode	8-11
8.3.2 Count source	8-13
8.3.3 Operation in timer mode	8-14
8.3.4 Selectable functions	8-15
[Precautions for timer mode]	8-17
8.4 Event counter mode	8-18
8.4.1 Setting for event counter mode	8-21
8.4.2 Operation in event counter mode	8-23
8.4.3 Switching between countup and countdown	8-24
8.4.4 Selectable functions	8-25
[Precautions for event counter mode]	8-28
8.5 One-shot pulse mode	8-29
8.5.1 Setting for one-shot pulse mode	8-31
8.5.2 Count source	8-33
8.5.3 Trigger	8-34
8.5.4 Operation in one-shot pulse mode	8-35
[Precautions for one-shot pulse mode]	8-37
8.6 Pulse width modulation (PWM) mode	8-38
8.6.1 Setting for PWM mode	8-40
8.6.2 Count source	8-42
8.6.3 Trigger	8-42
8.6.4 Operation in PWM mode	8-43
[Precautions for PWM mode]	8-47

CHAPTER 9 TIMER B

9.1 Overview	9-2
9.2 Block description	9-2
9.2.1 Counter and reload register (timer Bi register)	9-3
9.2.2 Count start register	9-4
9.2.3 Timer Bi mode register	9-5
9.2.4 Timer Bi interrupt control register	9-6
9.2.5 Port P5 direction register	9-7
9.3 Timer mode	9-8
9.3.1 Setting for timer mode	9-10
9.3.2 Count source	9-11
9.3.3 Operation in timer mode	9-12
[Precautions for timer mode]	9-13
9.4 Event counter mode	9-14
9.4.1 Setting for event counter mode	9-16
9.4.2 Operation in event counter mode	9-17
[Precautions for event counter mode]	9-18

Table of contents

9.5 Pulse period/Pulse width measurement mode	9-19
9.5.1 Setting for pulse period/pulse width measurement mode	9-21
9.5.2 Count source	9-22
9.5.3 Operation in pulse period/pulse width measurement mode	9-23
[Precautions for pulse period/pulse width measurement mode]	9-25
 CHAPTER 10 REAL-TIME OUTPUT <hr/>	
10.1 Overview	10-2
10.2 Block description	10-4
10.2.1 Real-time output control register	10-4
10.2.2 Pulse output data registers 0 and 1	10-5
10.2.3 Port P6 direction register	10-6
10.2.4 Timers A0 and A1	10-6
10.3 Setting of real-time output	10-7
10.4 Real-time output operation	10-10
 CHAPTER 11 SERIAL I/O <hr/>	
11.1 Overview	11-2
11.2 Block description	11-3
11.2.1 UARTi transmit/receive mode register	11-4
11.2.2 UARTi transmit/receive control register 0	11-6
11.2.3 UARTi transmit/receive control register 1	11-7
11.2.4 UARTi transmit register and UARTi transmit buffer register	11-9
11.2.5 UARTi receive register and UARTi receive buffer register	11-11
11.2.6 UARTi baud rate register (BRGi)	11-13
11.2.7 UARTi transmit interrupt control and UARTi receive interrupt control registers	11-14
11.2.8 Port P8 direction register	11-15
11.3 Clock synchronous serial I/O mode	11-16
11.3.1 Transfer clock (Synchronizing clock)	11-17
11.3.2 Method of transmission	11-18
11.3.3 Transmit operation	11-21
11.3.4 Method of reception	11-23
11.3.5 Receive operation	11-27
11.3.6 Processing on detecting overrun error	11-29
[Precautions for clock synchronous serial I/O mode]	11-30
11.4 Clock asynchronous serial I/O (UART) mode	11-31
11.4.1 Transfer rate (Frequency of transfer clock)	11-32
11.4.2 Transfer data format	11-33
11.4.3 Method of transmission	11-34
11.4.4 Transmit operation	11-38
11.4.5 Method of reception	11-41
11.4.6 Receive operation	11-44
11.4.7 Processing on detecting error	11-46
11.4.8 Sleep mode	11-47

CHAPTER 12 A-D CONVERTER

12.1 Overview	12-2
12.2 Block description	12-3
12.2.1 A-D control register	12-4
12.2.2 A-D sweep pin select register	12-6
12.2.3 A-D register i (i = 0 to 7)	12-7
12.2.4 A-D conversion interrupt control register	12-8
12.2.5 Port P7 direction register	12-9
12.3 A-D conversion method	12-10
12.4 Absolute accuracy and differential non-linearity error	12-12
12.4.1 Absolute accuracy	12-12
12.4.2 Differential non-linearity error	12-13
12.5 One-shot mode	12-14
12.5.1 Settings for one-shot mode	12-14
12.5.2 One-shot mode operation description	12-16
12.6 Repeat mode	12-17
12.6.1 Settings for repeat mode	12-17
12.6.2 Repeat mode operation description	12-19
12.7 Single sweep mode	12-20
12.7.1 Settings for single sweep mode	12-20
12.7.2 Single sweep mode operation description	12-22
12.8 Repeat sweep mode	12-24
12.8.1 Settings for repeat sweep mode	12-24
12.8.2 Repeat sweep mode operation description	12-26
12.9 Precautions for A-D converter	12-28

CHAPTER 13 DMA CONTROLLER

13.1 Overview	13-2
13.1.1 Performance overview	13-2
13.1.2 Bus use priority levels	13-3
13.1.3 Modes	13-3
13.2 Block description	13-6
13.2.1 Bus access control circuit	13-7
13.2.2 DMAC control register L	13-10
13.2.3 DMAC control register H	13-11
13.2.4 Source address register i (SARi)	13-12
13.2.5 Destination address register i (DARi)	13-12
13.2.6 Transfer counter register i (TCRi)	13-12
13.2.7 Incrementer/Decrementer	13-13
13.2.8 Decrementer	13-13
13.2.9 DMA latch	13-13
13.2.10 DMAi mode register L	13-14
13.2.11 DMAi mode register H	13-15
13.2.12 DMAi control register	13-16
13.2.13 DMAi interrupt control register	13-17
13.2.14 Port P9 direction register	13-18
[Precautions for DMAC]	13-18

Table of contents

13.3 Control	13-19
13.3.1 DMA enabling.....	13-19
13.3.2 DMA requests	13-20
13.3.3 Channel priority levels	13-21
13.3.4 Processing from DMA request until DMA transfer execution	13-23
13.3.5 Termination of DMA transfer.....	13-25
13.3.6 DMA transfer restart after termination	13-28
13.4 Operation	13-30
13.4.1 2-bus cycle transfer.....	13-30
[Precautions for 2-bus cycle transfer]	13-37
13.4.2 1-bus cycle transfer.....	13-38
[Precautions for 1-bus cycle transfer]	13-47
13.4.3 Burst transfer mode.....	13-48
[Precautions for burst transfer mode]	13-50
13.4.4 Cycle-steal transfer mode.....	13-51
[Precautions for cycle-steal transfer mode].....	13-52
13.5 Single transfer mode	13-54
13.5.1 Setting of single transfer mode	13-56
13.5.2 Operation in single transfer mode.....	13-59
13.6 Repeat transfer mode	13-61
13.6.1 Setting of repeat transfer mode	13-63
13.6.2 Operation in repeat transfer mode	13-66
13.7 Array chain transfer mode	13-68
13.7.1 Transfer parameter memory in array chain transfer mode	13-70
13.7.2 Setting of array chain transfer mode	13-72
13.7.3 Operation in array chain transfer mode	13-75
[Precautions for array chain transfer mode]	13-79
13.8 Link array chain transfer mode	13-80
13.8.1 Transfer parameter memory in link array chain transfer mode.....	13-82
13.8.2 Setting of link array chain transfer mode.....	13-84
13.8.3 Operation in link array chain transfer mode	13-87
[Precautions for link array chain transfer mode]	13-97
13.9 DMA transfer time	13-98
13.9.1 Cycle-steal transfer mode.....	13-98
13.9.2 Burst transfer mode.....	13-101

CHAPTER 14 DRAM CONTROLLER

14.1 Overview	14-2
14.2 Block description	14-2
14.2.1 DRAM control register	14-3
14.2.2 Refresh timer.....	14-5
14.2.3 Address comparator	14-6
14.2.4 $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ generating circuit	14-6
14.2.5 Address multiplexer	14-6
14.3 Setting for DRAMC	14-7
14.4 DRAMC operation	14-8
14.4.1 Waveform example of DRAM control signals	14-8
14.4.2 Refresh request	14-10
14.5 Precautions for DRAMC	14-12

CHAPTER 15 WATCHDOG TIMER

15.1 Block description	15-2
15.1.1 Watchdog timer	15-3
15.1.2 Watchdog timer frequency select register	15-3
15.2 Operation description	15-4
15.2.1 Basic operation	15-4
15.2.2 Stop period	15-6
15.2.3 Operation in Stop mode	15-6
15.3 Precautions for Watchdog timer	15-7

CHAPTER 16 APPLICATION

16.1 Memory connection	16-2
16.1.1 Memory connection model	16-2
16.1.2 How to calculate timing	16-4
16.1.3 Example of memory connection	16-20
16.1.4 Example of I/O expansion	16-40
16.2 Examples of using DMA controller	16-43
16.2.1 Example of Centronics interface configuration	16-43
16.2.2 Example of stepping motor control	16-48
16.2.3 Example of dynamic lighting for LED	16-53
16.3 Comparison of sample program execution rate	16-56
16.3.1 Differences depending on data bus width and software Wait	16-56
16.3.2 Comparison between software Wait ($f(X_{IN}) = 20 \text{ MHz}$) and software Wait + Ready ($f(X_{IN}) = 25 \text{ MHz}$)	16-58

APPENDIX

Appendix 1. Memory assignment of 7721 Group	17-2
Appendix 2. Memory assignment in SFR area	17-3
Appendix 3. Control registers	17-9
Appendix 4. Package outline	17-40
Appendix 5. Examples of handling unused pins	17-41
Appendix 6. Machine instructions	17-42
Appendix 7. Hexadecimal instruction code table	17-56
Appendix 8. Countermeasure against noise	17-59
Appendix 9. 7721 Group Q & A	17-65
Appendix 10. Differences between 7721 Group and 7720 Group	17-79
Appendix 11. Electrical characteristics	17-80
Appendix 12. Standard characteristics	17-107

- 1.2 Pin configuration
- 1.3 Pin description
- 1.4 Block diagram

EOL announced

DESCRIPTION

1.1 Performance overview

1.1 Performance overview

Table 1.1.1 lists the performance overview of the M37721.

Table 1.1.1 M37721 performance overview

Parameters		Functions	
Number of basic instructions		103	
Instruction execution time		160 ns (the minimum instruction at $f(X_{IN}) = 25$ MHz)	
External clock input frequency $f(X_{IN})$		25 MHz (maximum)	
Memory sizes	ROM	External	
	RAM	M37721S2BFP	1024 bytes
		M37721S1BFP	512 bytes
Programmable Input/Output ports	P5–P10	8 bits X 6	
	P4	5 bits X 1	
Multifunctional timers	TA0–TA4	16 bits X 5	
	TB0–TB2	16 bits X 3	
Serial I/O	UART0, UART1	(UART or clock synchronous serial I/O) X 2	
A-D converter		8-bit successive approximation method X 1 (8 channels)	
Watchdog timer		12 bits X 1	
DMA controller		4 channels Maximum transfer rate : 12.5 Mbytes/sec. (at $f(X_{IN}) = 25$ MHz, 1-bus cycle transfer) Maximum transfer rate : 6.25 Mbytes/sec. (at $f(X_{IN}) = 25$ MHz, 2-bus cycle transfer)	
DRAM controller		CAS before RAS refreshing method	
Real-time output		4 bits X 2 channels or 6 bits X 1 channel + 2 bits X 1 channel	
Interrupts		3 external, 20 internal (priority levels 0 to 7 can be set for each interrupt with software)	
Clock generating circuit		Built-in (externally connected to a ceramic resonator or a quartz-crystal oscillator)	
Supply voltage		5 V ± 10 %	
Power dissipation		135 mW (at $f(X_{IN}) = 25$ MHz, typ.)	
Port Input/Output characteristics	Input/Output withstand voltage	5 V	
	Output current	5 mA	
Memory expansion		Maximum 16 Mbytes	
Operating temperature range		-20°C to 85°C	
Device structure		CMOS high-performance silicon gate process	
Package		100-pin plastic molded QFP	

1.2 Pin configuration

Figure 1.2.1 shows the M37721S2BFP pin configuration.

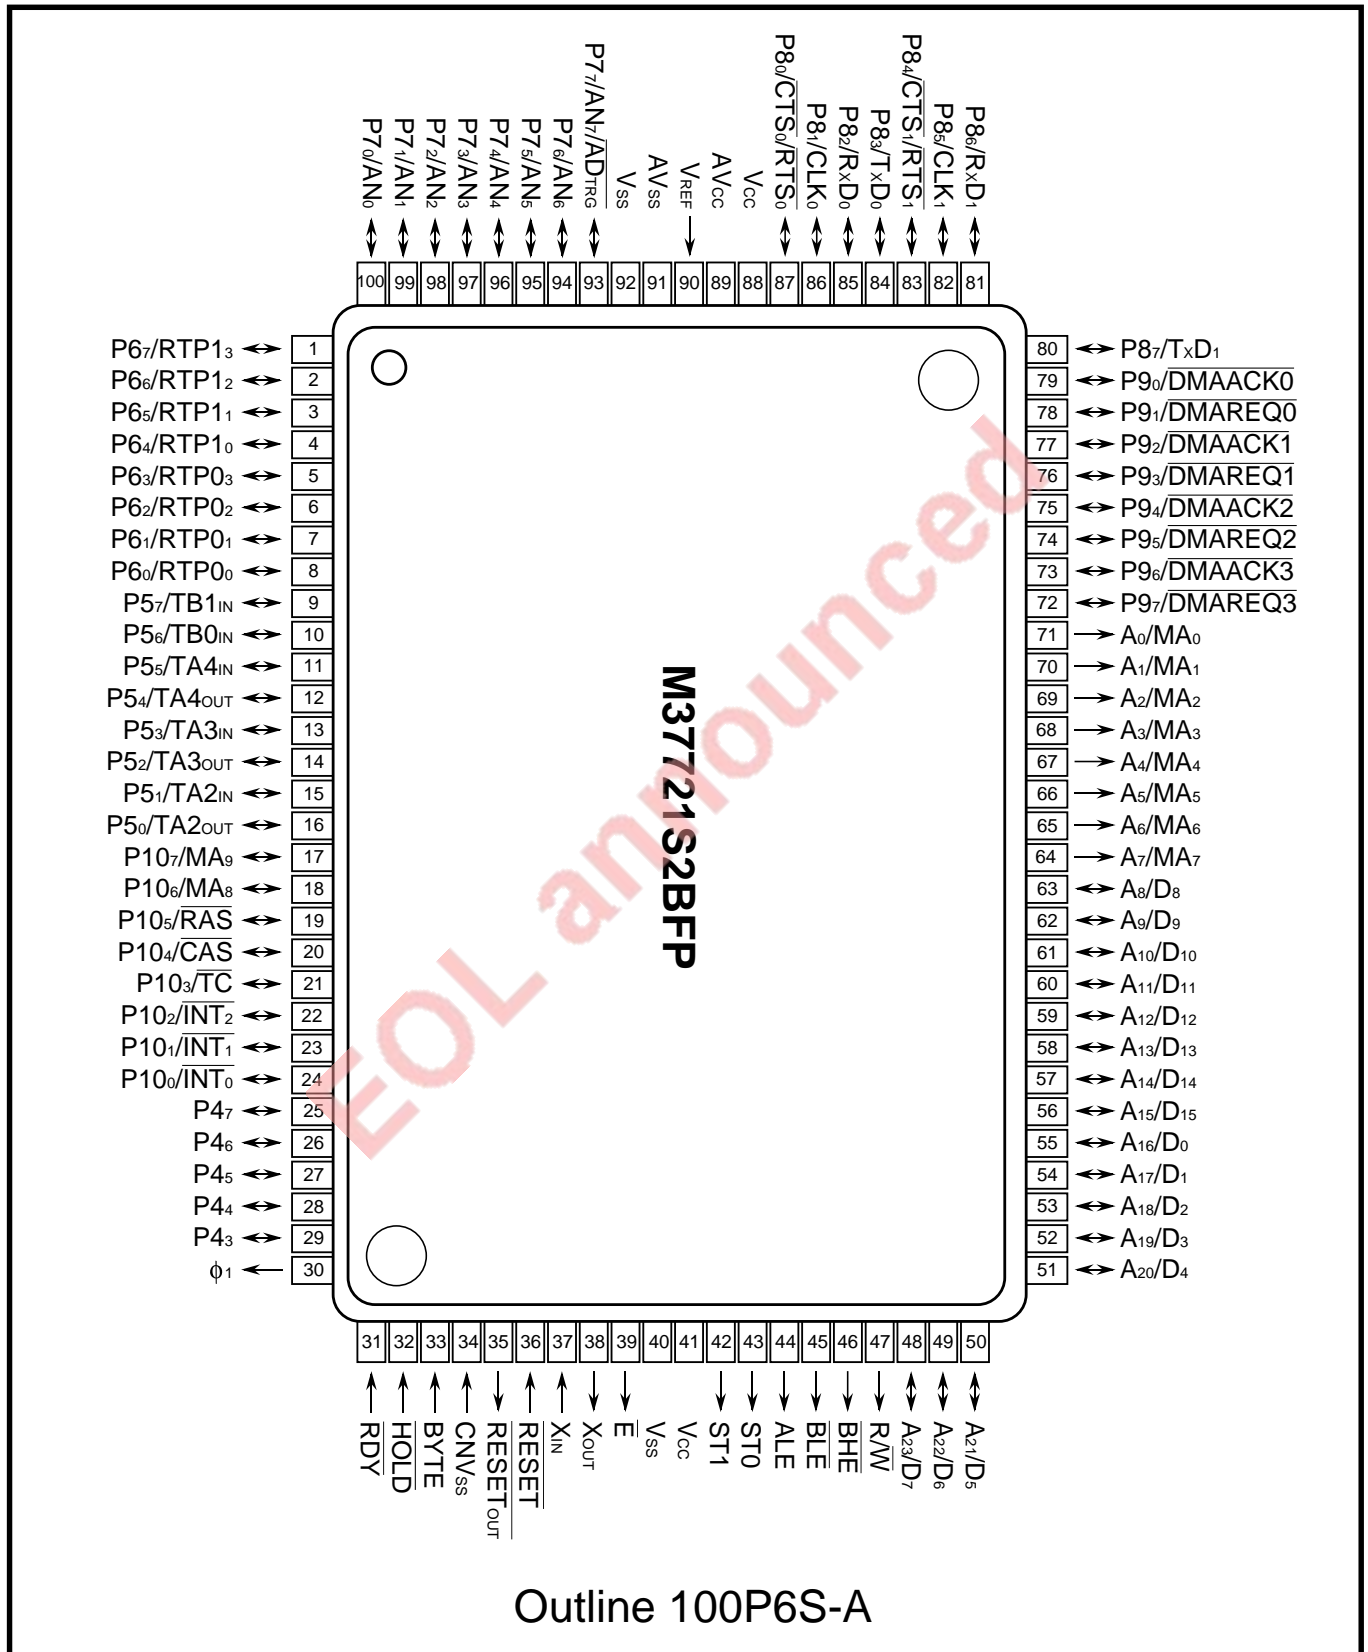

Fig. 1.2.1 M37721S2BFP pin configuration (top view)

DESCRIPTION

1.3 Pin description

1.3 Pin description

Tables 1.3.1 to 1.3.3 list the pin description.

Table 1.3.1 Pin description (1)

Pin	Name	Input/Output	Functions															
Vcc, Vss	Power supply		Supply 5 V \pm 10 % to Vcc pin and 0 V to Vss pin.															
CNVss	CNVss	Input	Connect to Vss or Vcc pin.															
$\overline{\text{RESET}}$	Reset input	Input	The microcomputer is reset when supplying “L” level to this pin.															
$\text{RESET}_{\text{OUT}}$	Reset output	Output	When input to $\overline{\text{RESET}}$ pin is “L,” this pin outputs “L.” Output from this pin returns “H” after the release of reset. When writing “1” to the software reset bit, this pin outputs “L.”															
X _{IN}	Clock input	Input	These are I/O pins of the internal clock generating circuit. Connect a ceramic resonator or quartz-crystal oscillator between pins X _{IN} and X _{OUT} . When using an external clock, the clock source should be input to X _{IN} pin and X _{OUT} pin should be left open.															
X _{OUT}	Clock output	Output																
$\overline{\text{E}}$	Enable output	Output	Data/instruction code read or data write is performed when output from this pin is “L” level.															
BYTE	External data bus width selection input	Input	Input level to this pin determines whether the external data bus has a 16-bit width or an 8-bit width. The width is 16 bits when the level is “L”, and 8 bits when the level is “H”.															
ST0 ST1	Status signal output	Output	The bus use state is output in 2-bit code. <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th>ST1</th> <th>ST0</th> <th>Bus use state</th> </tr> </thead> <tbody> <tr> <td>0</td> <td>0</td> <td>DRAM refresh</td> </tr> <tr> <td>0</td> <td>1</td> <td>Hold</td> </tr> <tr> <td>1</td> <td>0</td> <td>DMA</td> </tr> <tr> <td>1</td> <td>1</td> <td>CPU</td> </tr> </tbody> </table>	ST1	ST0	Bus use state	0	0	DRAM refresh	0	1	Hold	1	0	DMA	1	1	CPU
ST1	ST0	Bus use state																
0	0	DRAM refresh																
0	1	Hold																
1	0	DMA																
1	1	CPU																
AVcc AVss	Analog supply input		The power supply pin for the A-D converter. Connect AVcc to Vcc pin. Connect AVss to Vss pin.															
V _{REF}	Reference voltage input	Input	This is a reference voltage input pin for the A-D converter.															

DESCRIPTION

1.3 Pin description

Table 1.3.2 Pin description (2)

Pin	Name	Input/Output	Functions
A_0/\overline{MA}_0- A_7/\overline{MA}_7	Address low-order/ DRAM address	Output	Low-order 8 bits (A_0-A_7) of the address are output. When the DRAM is accessed, the row and column addresses are output with the time-sharing.
A_8/\overline{D}_8- A_{15}/\overline{D}_{15}	Address middle-order/ data high-order	I/O	<ul style="list-style-type: none"> ● External data bus width = 8 bits (When the BYTE pin is "H" level) Middle-order 8 bits (A_8-A_{15}) of the address are output. ● External data bus width = 16 bits (When the BYTE pin is "L" level) Data (D_8-D_{15}) input/output and output of the middle-order 8 bits (A_8-A_{15}) of the address are performed with the time-sharing.
A_{16}/\overline{D}_0- A_{23}/\overline{D}_7	Address high-order/ data low-order	I/O	Data (D_0-D_7) input/output and output of the high-order 8 bits ($A_{16}-A_{23}$) of the address are performed with the time-sharing.
$\overline{R}/\overline{W}$, \overline{BHE} , \overline{BLE} , ALE	Memory control signal output	Output	<ul style="list-style-type: none"> ● $\overline{R}/\overline{W}$ The Read/Write signal indicates the data bus state. The state is read while this signal is "H" level, and write while this signal is "L" level. ● \overline{BHE} "L" level is output when an odd-numbered address is accessed. ● \overline{BLE} "L" level is output when an even-numbered address is accessed. ● ALE This is used to obtain only the address from address and data multiplex signals.
\overline{HOLD}	Hold input	Input	The microcomputer is in Hold state while "L" level is input to the \overline{HOLD} pin.
\overline{RDY}	Ready input	Input	The microcomputer is in Ready state while "L" level is input to the \overline{RDY} pin.
ϕ_1	Clock ϕ_1 output	Output	This is the ϕ_1 output pin.

DESCRIPTION

1.3 Pin description

Table 1.3.3 Pin description (3)

Pin	Name	Input/Output	Functions
P4 ₃ –P4 ₇	I/O port P4	I/O	Port P4 is a 5-bit CMOS I/O port. This port has an I/O direction register and each pin can be programmed for input or output.
P5 ₀ –P5 ₇	I/O port P5	I/O	Port P5 is an 8-bit I/O port with the same function as P4. These pins can be programmed as I/O pins for Timers A2–A4 and I/O pins for Timers B0, B1.
P6 ₀ –P6 ₇	I/O port P6	I/O	Port P6 is an 8-bit I/O port with the same function as P4. These pins can be programmed as output pins for the real-time output.
P7 ₀ –P7 ₇	I/O port P7	I/O	Port P7 is an 8-bit I/O port with the same function as P4. These pins can be programmed as input pins for A-D converter.
P8 ₀ –P8 ₇	I/O port P8	I/O	Port P8 is an 8-bit I/O port with the same function as P4. These pins can be programmed as I/O pins for Serial I/O.
P9 ₀ –P9 ₇	I/O port P9	I/O	Port P9 is an 8-bit I/O port with the same function as P4. These pins can be programmed as I/O pins for DMA controller.
P10 ₀ – P10 ₇	I/O port P10	I/O	Port P10 is an 8-bit I/O port with the same function as P4. These pins can be programmed as I/O pin for \overline{TC} and output pins for DRAM controller. P10 ₀ –P10 ₂ also function as input pins for $\overline{INT_0}$ – $\overline{INT_2}$.

DESCRIPTION

1.4 Block diagram

MEMORANDUM

EOL announced

CHAPTER 2

CENTRAL PROCESSING UNIT (CPU)

- 2.1 Central processing unit
- 2.2 Bus interface unit
- 2.3 Access space
- 2.4 Memory assignment
- 2.5 Bus access right

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit

2.1 Central processing unit

The CPU (Central Processing Unit) has the ten registers as shown in Figure 2.1.1.

Fig. 2.1.1 CPU registers structure

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit

2.1.1 Accumulator (Acc)

Accumulators A and B are available.

(1) Accumulator A (A)

Accumulator A is the main register of the microcomputer. The transaction of data such as calculation, data transfer, and input/output are performed mainly through accumulator A. It consists of 16 bits, and the low-order 8 bits can also be used separately. The data length flag (m) determines whether the register is used as a 16-bit register or as an 8-bit register. When an 8-bit register is selected, only the low-order 8 bits of accumulator A are used and the contents of the high-order 8 bits is unchanged.

(2) Accumulator B (B)

Accumulator B is a 16-bit register with the same function as accumulator A. Accumulator B can be used instead of accumulator A. The use of accumulator B, however except for some instructions, requires more instruction bytes and execution cycles than that of accumulator A. Accumulator B is also controlled by the data length flag (m) just as in accumulator A.

2.1.2 Index register X (X)

Index register X consists of 16 bits and the low-order 8 bits can also be used separately. The index register length flag (x) determines whether the register is used as a 16-bit register or as an 8-bit register. When an 8-bit register is selected, only the low-order 8 bits of index register X are used and the contents of the high-order 8 bits is unchanged.

In an addressing mode in which index register X is used as an index register, the address obtained by adding the contents of this register to the operand's contents is accessed.

In the **MVP** or **MVN** instruction, a block transfer instruction, the contents of index register X indicate the low-order 16 bits of the source address. The third byte of the instruction is the high-order 8 bits of the source address.

Note: Refer to “7700 Family Software Manual” for addressing modes.

2.1.3 Index register Y (Y)

Index register Y is a 16-bit register with the same function as index register X. Just as in index register X, the index register length flag (x) determines whether this register is used as a 16-bit register or as an 8-bit register.

In the **MVP** or **MVN** instruction, a block transfer instruction, the contents of index register Y indicate the low-order 16 bits of the destination address. The second byte of the instruction is the high-order 8 bits of the destination address.

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit

2.1.4 Stack pointer (S)

The stack pointer (S) is a 16-bit register. It is used for a subroutine call or an interrupt. It is also used when addressing modes using the stack are executed. The contents of S indicate an address (stack area) for storing registers during subroutine calls and interrupts. Stack area is selected by the stack bank select bit described later (bit 7 at address 5E₁₆). The stack area is specified to bank 0₁₆ when the stack bank select bit is “0,” and the stack area is specified to bank FF₁₆ when it is “1.”

When an interrupt request is accepted, the microcomputer stores the contents of the program bank register (PG) at the address indicated by the contents of S and decrements the contents of S by 1. Then the contents of the program counter (PC) and the processor status register (PS) are stored. The contents of S after accepting an interrupt request is equal to the contents of S decremented by 5 before the accepting of the interrupt request. (Refer to “**Figure 2.1.2.**”)

When completing the process in the interrupt routine and returning to the original routine, the contents of registers stored in the stack area are restored into the original registers in the reverse sequence (PS→PC→PG) by executing the **RTI** instruction. The contents of S is returned to the state before accepting an interrupt request.

The same operation is performed during a subroutine call, however, the contents of PS is not automatically stored. (The contents of PG may not be stored. This depends on the addressing mode.)

The user should store registers other than those described above with software when the user needs them during interrupts or subroutine calls.

Additionally, initialize S at the beginning of the program because its contents are undefined at reset. The stack area changes when subroutines are nested or when multiple interrupt requests are accepted. Therefore, make sure of the subroutine’s nesting depth not to destroy the necessary data.

Note: Refer to “**7700 Family Software Manual**” for addressing modes.

Fig. 2.1.2 Stored registers of the stack area

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit

2.1.5 Program counter (PC)

The program counter is a 16-bit counter that indicates the low-order 16 bits of the address (24 bits) at which an instruction to be executed next (in other words, an instruction to be read out from an instruction queue buffer next) is stored. The contents of the high-order program counter (PC_H) become “FF₁₆,” and the low-order program counter (PC_L) becomes “FE₁₆” at reset. The contents of the program counter becomes the contents of the reset’s vector address (addresses FFFE₁₆, FFFF₁₆) immediately after reset.

Figure 2.1.3 shows the program counter and the program bank register.

Fig. 2.1.3 Program counter and program bank register

2.1.6 Program bank register (PG)

The access space is divided in units of 64 Kbytes. This unit is called “bank.” (Refer to section “2.3 Access space.”)

The program bank register is an 8-bit register. This register indicates the high-order 8 bits (bank) of the address (24 bits) at which an instruction to be executed next (in other words, an instruction to be read out from an instruction queue buffer next) is stored. These 8 bits are called bank.

When a carry occurs after adding the contents of the program counter or adding the offset value to the contents of the program counter in the branch instruction and others, the contents of the program bank register is automatically incremented by 1. When a borrow occurs after subtracting the contents of the program counter, the contents of the program bank register is automatically decremented by 1. Accordingly, there is no need to consider bank boundaries in programming, usually.

This register is cleared to “00₁₆” at reset.

2.1.7 Data bank register (DT)

The data bank register is an 8-bit register. In the following addressing modes using the data bank register, the contents of this register is used as the high-order 8 bits (bank) of a 24-bit address to be accessed. Use the LDT instruction to set a value to this register.

This register is cleared to “00₁₆” at reset.

- Stack pointer relative indirect indexed Y

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit

2.1.8 Direct page register (DPR)

The direct page register is a 16-bit register. The contents of this register indicate the direct page area which is allocated in bank 0₁₆ or in the space across banks 0₁₆ and 1₁₆. The following addressing modes use the direct page register.

The contents of the direct page register indicate the base address (the lowest address) of the direct page area. The space which extends to 256 bytes above that address is specified as a direct page.

The direct page register can contain a value from "0000₁₆" to "FFFF₁₆." When it contains a value equal to or more than "FF01₁₆," the direct page area spans the space across banks 0₁₆ and 1₁₆.

When the contents of low-order 8 bits of the direct page register is "00₁₆," the number of cycles required to generate an address is 1 cycle smaller than the number when its contents are not "00₁₆." Accordingly, the access efficiency can be enhanced in this case.

This register is cleared to "0000₁₆" at reset.

Figure 2.1.4 shows a setting example of the direct page area.

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit

2.1.9 Processor status register (PS)

The processor status register is an 11-bit register.

Figure 2.1.5 shows the structure of the processor status register.

Fig. 2.1.5 Processor status register structure

(1) Bit 0: Carry flag (C)

It retains a carry or a borrow generated in the arithmetic and logic unit (ALU) during an arithmetic operation. This flag is also affected by shift and rotate instructions. When the **BCC** or **BCS** instruction is executed, this flag's contents determine whether the program causes a branch or not.

Use the **SEC** or **SEP** instruction to set this flag to “1,” and use the **CLC** or **CLP** instruction to clear it to “0.”

(2) Bit 1: Zero flag (Z)

It is set to “1” when a result of an arithmetic operation or data transfer is “0,” and cleared to “0” when otherwise. When the **BNE** or **BEQ** instruction is executed, this flag's contents determine whether the program causes a branch or not.

Use the **SEP** instruction to set this flag to “1,” and use the **CLP** instruction to clear it to “0.”

Note: This flag is invalid in the decimal mode addition (the **ADC** instruction).

(3) Bit 2: Interrupt disable flag (I)

It disables all maskable interrupts (interrupts other than watchdog timer, the **BRK** instruction, and zero division). Interrupts are disabled when this flag is “1.” When an interrupt request is accepted, this flag is automatically set to “1” to avoid multiple interrupts. Use the **SEI** or **SEP** instruction to set this flag to “1,” and use the **CLI** or **CLP** instruction to clear it to “0.” This flag is set to “1” at reset.

(4) Bit 3: Decimal mode flag (D)

It determines whether addition and subtraction are performed in binary or decimal. Binary arithmetic is performed when this flag is “0.” When it is “1,” decimal arithmetic is performed with 8 bits treated as two digits decimal (the data length flag (m) = “1”) or 16 bits treated as four digits decimal (the data length flag (m) = “0”). Decimal adjust is automatically performed. Decimal operation is possible only with the **ADC** and **SBC** instructions. Use the **SEP** instruction to set this flag to “1,” and use the **CLP** instruction to clear it to “0.” This flag is cleared to “0” at reset.

(5) Bit 4: Index register length flag (x)

It determines whether each of index register X and index register Y is used as a 16-bit register or an 8-bit register. That register is used as a 16-bit register when this flag is “0,” and as an 8-bit register when it is “1.” Use the **SEP** instruction to set this flag to “1,” and use the **CLP** instruction to clear it to “0.” This flag is cleared to “0” at reset.

Note: When transferring data between registers which are different in bit length, the data is transferred with the length of the destination register, but except for the **TXA**, **TYA**, **TXB**, **TYB**, and **TXS** instructions. Refer to “7700 Family Software Manual” for details.

CENTRAL PROCESSING UNIT (CPU)

2.1 Central processing unit

(6) Bit 5: Data length flag (m)

It determines whether to use a data as a 16-bit unit or as an 8-bit unit. A data is treated as a 16-bit unit when this flag is “0,” and as an 8-bit unit when it is “1.”

Use the **SEM** or **SEP** instruction to set this flag to “1,” and use the **CLM** or **CLP** instruction to clear it to “0.” This flag is cleared to “0” at reset.

Note: When transferring data between registers which are different in bit length, the data is transferred with the length of the destination register, but except for the **TXA**, **TYA**, **TXB**, **TYB**, and **TXS** instructions. Refer to “7700 Family Software Manual” for details.

(7) Bit 6: Overflow flag (V)

It is used when adding or subtracting with a word regarded as signed binary. When the data length flag (m) is “0,” the overflow flag is set to “1” when the result of addition or subtraction exceeds the range between -32768 and $+32767$, and cleared to “0” in all other cases. When the data length flag (m) is “1,” the overflow flag is set to “1” when the result of addition or subtraction exceeds the range between -128 and $+127$, and cleared to “0” in all other cases.

The overflow flag is also set to “1” when a result of division exceeds the register length to be stored in a division instruction **DIV**.

When the **BVC** or **BVS** instruction is executed, this flag’s contents determine whether the program causes a branch or not.

Use the **SEP** instruction to set this flag to “1,” and use the **CLV** or **CLP** instruction to clear it to “0.”

Note: This flag is invalid in the decimal mode.

(8) Bit 7: Negative flag (N)

It is set to “1” when a result of arithmetic operation or data transfer is negative. (Bit 15 of the result is “1” when the data length flag (m) is “0,” or bit 7 of the result is “1” when the data length flag (m) is “1.”) It is cleared to “0” in all other cases. When the **BPL** or **BMI** instruction is executed, this flag determines whether the program causes a branch or not. Use the **SEP** instruction to set this flag to “1,” and use the **CLP** instruction to clear it to “0.”

Note: This flag is invalid in the decimal mode.

(9) Bits 10 to 8: Processor interrupt priority level (IPL)

These three bits can determine the processor interrupt priority level to one of levels 0 to 7. The interrupt is enabled when the interrupt priority level of a required interrupt, which is set in each interrupt control register, is higher than IPL. When an interrupt request is accepted, IPL is stored in the stack area, and IPL is replaced by the interrupt priority level of the accepted interrupt request. There are no instruction to directly set or clear the bits of IPL. IPL can be changed by storing the new IPL into the stack area and updating the processor status register with the **PUL** or **PLP** instruction. The contents of IPL is cleared to “000₂” at reset.

2.2 Bus interface unit

A bus interface unit (BIU) is built-in between the central processing unit (CPU) and memory•I/O devices. BIU's function and operation are described below.

When externally connecting devices, refer to “**CHAPTER 3. CONNECTION WITH EXTERNAL DEVICES.**”

2.2.1 Overview

Transfer operation between the CPU and memory•I/O devices is always performed via the BIU.

- ① The BIU reads an instruction from the memory before the CPU executes it.
- ② When the CPU reads data from the memory•I/O device, the CPU first specifies the address from which data is read to the BIU. The BIU reads data from the specified address and passes it to the CPU.
- ③ When the CPU writes data to the memory•I/O device, the CPU first specifies the address to which data is written to the BIU and write data. The BIU writes the data to the specified address.
- ④ To perform the above operations ① to ③, the BIU inputs and outputs the control signals, and control the bus.

Figure 2.2.1 shows the bus and bus interface unit (BIU).

EOL announced

CENTRAL PROCESSING UNIT (CPU)

2.2 Bus interface unit

Fig. 2.2.1 Bus and bus interface unit (BIU)

CENTRAL PROCESSING UNIT (CPU)

2.2 Bus interface unit

2.2.2 Functions of bus interface unit (BIU)

The bus interface unit (BIU) consists of four registers shown in Figure 2.2.2. Table 2.2.1 lists the functions of each register.

Fig. 2.2.2 Register structure of bus interface unit (BIU)

Table 2.2.1 Functions of each register

Name	Functions
Program address register	Indicates the storage address for the instruction which is next taken into the instruction queue buffer.
Instruction queue buffer	Temporarily stores the instruction which has been taken in.
Data address register	Indicates the address for the data which is next read from or written to.
Data buffer	Temporarily stores the data which is read from the memory•I/O device by the BIU or which is written to the memory•I/O device by the CPU.

CENTRAL PROCESSING UNIT (CPU)

2.2 Bus interface unit

The CPU and the bus send or receive data via BIU because each operates based on different clocks (**Note**). The BIU allows the CPU to operate at high speed without waiting for access to the memory · I/O devices that require a long access time.

The BIU's functions are described bellow.

Note: The CPU operates based on ϕ_{CPU} . The period of ϕ_{CPU} is normally the same as that of ϕ . The internal bus operates based on the \bar{E} signal. The period of the \bar{E} signal is twice that of ϕ at a minimum.

(1) Reading out instruction (Instruction prefetch)

When the CPU does not require to read or write data, that is, when the bus is not in use, the BIU reads instructions from the memory and stores them in the instruction queue buffer. This is called instruction prefetch.

The CPU reads instructions from the instruction queue buffer and executes them, so that the CPU can operate at high speed without waiting for access to the memory which requires a long access time.

When the instruction queue buffer becomes empty or contains only 1 byte of an instruction, the BIU performs instruction prefetch. The instruction queue buffer can store instructions up to 3 bytes.

The contents of the instruction queue buffer is initialized when a branch or jump instruction is executed, and the BIU reads a new instruction from the destination address.

When instructions in the instruction queue buffer are insufficient for the CPU's needs, the BIU extends the pulse duration of clock ϕ_{CPU} in order to keep the CPU waiting until the BIU fetches the required number of instructions or more.

(2) Reading data from memory·I/O device

The CPU specifies the storage address of data to be read to the BIU's data address register, and requires data. The CPU waits until data is ready in the BIU.

The BIU outputs the address received from the CPU onto the address bus, reads contents at the specified address, and takes it into the data buffer.

The CPU continues processing, using data in the data buffer.

However, if the BIU uses the bus for instruction prefetch when the CPU requires to read data, the BIU keeps the CPU waiting.

(3) Writing data to memory·I/O device

The CPU specifies the address of data to be written to the BIU's data address register. Then, the CPU writes data into the data buffer. The BIU outputs the address received from the CPU onto the address bus and writes data in the data buffer into the specified address.

The CPU advances to the next processing without waiting for completion of BIU's write operation.

However, if the BIU uses the bus for instruction prefetch when the CPU requires to write data, the BIU keeps the CPU waiting.

(4) Bus control

To perform the above operations (1) to (3), the BIU inputs and outputs the control signals, and controls the address bus and the data bus. The cycle in which the BIU controls the bus and accesses the memory·I/O device is called the bus cycle.

Refer to "**CHAPTER 3. CONNECTION WITH EXTERNAL DEVICES**" about the bus cycle at accessing the external devices.

CENTRAL PROCESSING UNIT (CPU)

2.2 Bus interface unit

2.2.3 Operation of bus interface unit (BIU)

Figure 2.2.3 shows the basic operating waveforms of the bus interface unit (BIU).

About signals which are input/output externally when accessing external devices, refer to “CHAPTER 3. CONNECTION WITH EXTERNAL DEVICES.”

(1) When fetching instructions into the instruction queue buffer

- ① When the instruction which is next fetched is located at an even address, the BIU fetches 2 bytes at a time with the timing of waveform (a).
However, when accessing an external device which is connected with the 8-bit external data bus width (BYTE = “H”), only 1 byte of the instruction is fetched.
- ② When the instruction which is next fetched is located at an odd address, the BIU fetches only 1 byte with the timing of waveform (a). The contents at the even address are not taken into the instruction queue buffer.

(2) When reading or writing data to and from the memory•I/O device

- ① When accessing a 16-bit data which begins at an even address, waveform (a) is applied. The 16 bits of data are accessed at a time.
- ② When accessing a 16-bit data which begins at an odd address, waveform (b) is applied. The 16 bits of data are accessed separately in 2 operations, 8 bits at a time. Invalid data is not fetched into the data buffer.
- ③ When accessing an 8-bit data at an even address, waveform (a) is applied. The data at the odd address is not fetched into the data buffer.
- ④ When accessing an 8-bit data at an odd address, waveform (a) is applied. The data at the even address is not fetched into the data buffer.

For instructions that are affected by the data length flag (m) and the index register length flag (x), operation ① or ② is applied when flag m or x = “0”; operation ③ or ④ is applied when flag m or x = “1.”

CENTRAL PROCESSING UNIT (CPU)

2.2 Bus interface unit

Fig. 2.2.3 Basic operating waveforms of bus interface unit (BIU)

2.3 Access space

Figure 2.3.1 shows the M37721's access space.

By combination of the program counter (PC), which is 16 bits of structure, and the program bank register (PG), a 16-Mbyte space from addresses 0_{16} to $FFFFFF_{16}$ can be accessed. For details about access of an external area, refer to "CHAPTER 3. CONNECTION WITH EXTERNAL DEVICES."

The memory and I/O devices are assigned in the same access space. Accordingly, it is possible to perform transfer and arithmetic operations using the same instructions without discrimination of the memory from I/O devices.

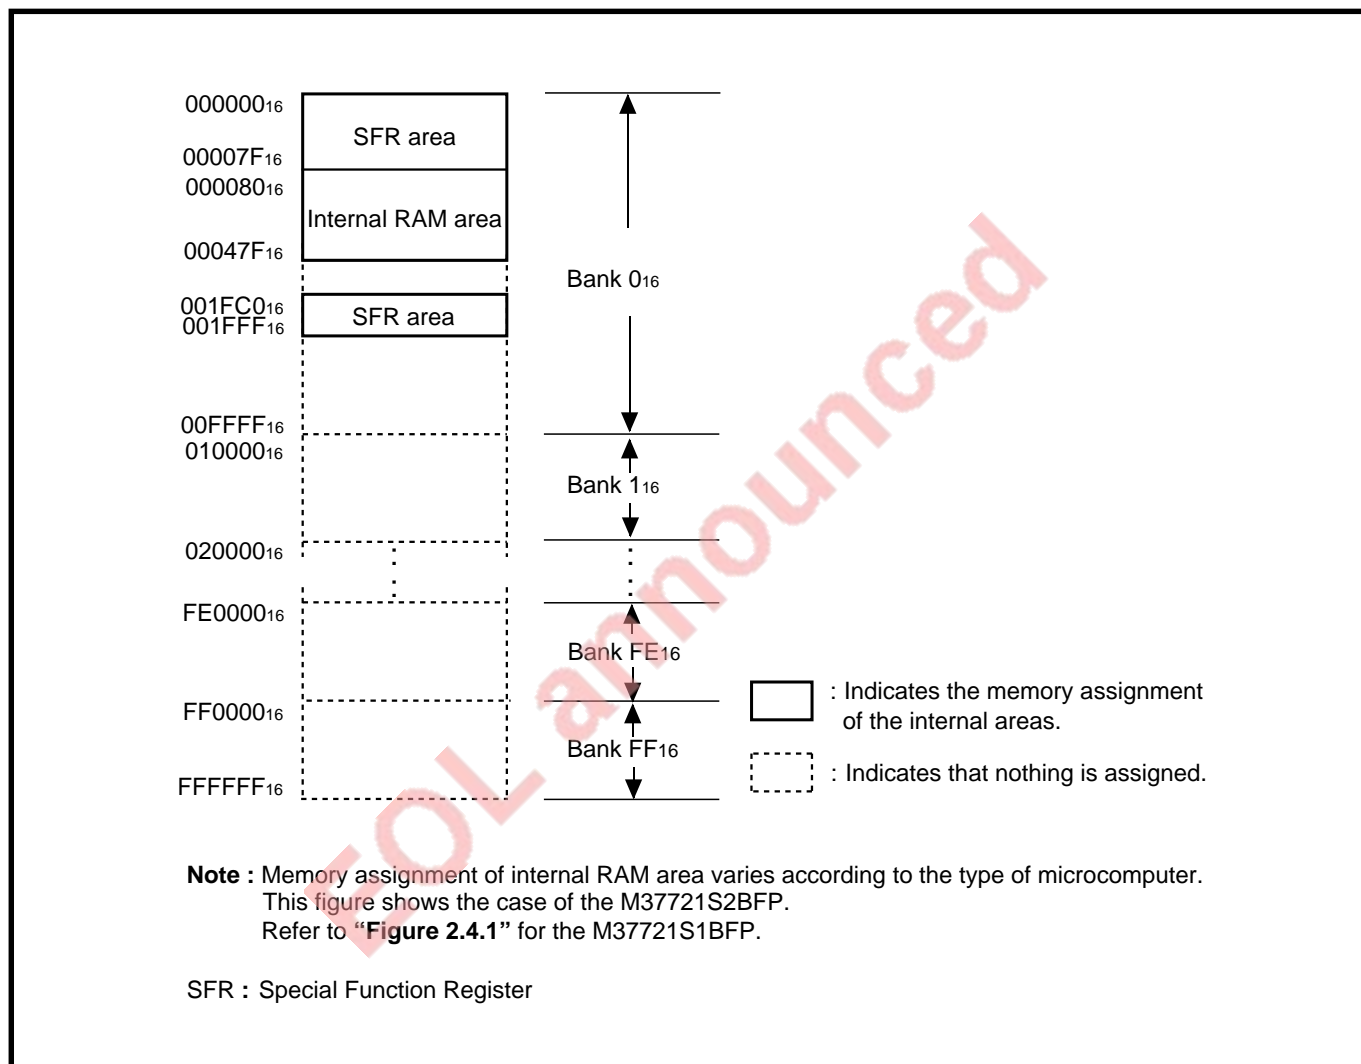

Fig. 2.3.1 M37721's access space

CENTRAL PROCESSING UNIT (CPU)

2.3 Access space

2.3.1 Banks

The access space is divided in units of 64 Kbytes. This unit is called “bank.” The high-order 8 bits of address (24 bits) indicate a bank, which is specified by the program bank register (PG) or data bank register (DT). Each bank can be accessed efficiently by using an addressing mode that uses the data bank register (DT).

If the program counter (PC) overflows at a bank boundary, the contents of the program bank register (PG) is incremented by 1. If a borrow occurs in the program counter (PC) as a result of subtraction, the contents of the program bank register (PG) is decremented by 1. Normally, accordingly, the user can program without concern for bank boundaries.

SFR (Special Function Register) and internal RAM are assigned in bank 016. For details, refer to section “2.4 Memory assignment.”

2.3.2 Direct page

A 256-byte space specified by the direct page register (DPR) is called “direct page.” A direct page is specified by setting the base address (the lowest address) of the area to be specified as a direct page into the direct page register (DPR).

By using a direct page addressing mode, a direct page can be accessed with less instruction cycles than otherwise.

Note: Refer also to section “2.1 Central processing unit.”

EOL announced

2.4 Memory assignment

This section describes the internal area's memory assignment. For more information about the external area, refer also to "CHAPTER 3. CONNECTION WITH EXTERNAL DEVICES."

Figure 2.4.1 shows the memory assignment.

2.4.1 Memory assignment in internal area

SFR (Special Function Register) and internal RAM are assigned in the internal area.

(1) SFR area

The registers for setting internal peripheral devices are assigned at addresses 0_{16} to $7F_{16}$ and $1FC_{16}$ to $1FFF_{16}$. This area is called SFR. Figures 2.4.2 and 2.4.3 show the SFR area's memory assignment. For each register in the SFR area, refer to each functional description in this manual.

For the state of the SFR area immediately after reset, refer to section "4.1.2 State of CPU, SFR area, and internal RAM area."

(2) Internal RAM area

The M37721S2BFP (**Note 1**) assigns the 1024-byte static RAM at addresses 80_{16} to $47F_{16}$. 512 bytes of that can be selected either it is used as the internal RAM or it is used as the external area. (**Note 2**)

The internal RAM area is used as a stack area (**Note 3**), as well as an area to store data. Accordingly, note that set the nesting depth of a subroutine and multiple interrupts' level not to destroy the necessary data.

Notes 1: The M37721S1BFP assigns the 512-byte static RAM at addresses 80_{16} to $27F_{16}$.

2: The internal RAM area becomes 512 bytes after reset because the internal RAM area select bit is "0."

3: Either bank 0_{16} or bank FF_{16} can be selected as the stack area by the stack bank select bit (bit 7 at address $5E_{16}$).

Figure 2.4.4 shows the structure of the processor mode registers 0, 1.

CENTRAL PROCESSING UNIT (CPU)

2.4 Memory assignment

2.4.2 External area

Table 2.4.1 lists the external area. When connecting the external device, follow the procedure described below:

- Connect the ROM to addresses $FFCE_{16}$ to $FFFF_{16}$ because they are interrupt vector table.
- Stack area can be assigned to bank 0_{16} or bank FF_{16} . Select the stack area by the stack bank select bit (bit 7 at address $5E_{16}$). (Refer to “**Figure 2.4.4.**”)
- When using the DRAM controller, DRAM area can be selected from address $FFFFFF_{16}$ toward the low-order address in a unit of 1 Mbytes. (Refer to “**CHAPTER 14. DRAM CONTROLLER.**”)

In the case connecting an external device to the area where overlaps the internal area, when reading out the overlapping area, the central processing unit (CPU) take in data of the internal area and do not take in data of the external area.

When writing to the overlapping area, data is written to the internal area. The signal is output to the external at the same timing when data is written to the internal area.

Table 2.4.1 External area

Type name	M37721S2BFP		M37721S1BFP

CENTRAL PROCESSING UNIT (CPU)

2.5 Bus access right

2.5 Bus access right

The M37721's bus is used for DRAMC, Hold function, and DMAC besides CPU. When the bus requests of two or more source are detected at the same timing, the highest bus access priority levels get the access right.

The bus priority levels are fixed by hardware. Additionally the bus use state is output from the status signal output pins ST0 and ST1. Table 2.5.1 lists the bus use priority levels and the status signals depending on the bus use state.

Table 2.5.1 Bus use priority levels and status signals depending on bus use state

Bus use priority levels	Bus use state	Status signal	
		ST1	ST0
1 (Highest)	DRAM refresh	0	0
2	Hold	0	1
3	DMAC	1	0
4 (Lowest)	CPU (Including the term that CPU does not use the bus during calculation etc.)	1	1

For details, refer to section “13.2.1 Bus access control circuit” and chapter for each peripheral devices.

CHAPTER 3

CONNECTION WITH EXTERNAL DEVICES

- 3.1 Signals required for accessing external devices
 - 3.2 Software Wait
 - 3.3 Ready function
 - 3.4 Hold function
- [Precautions for Hold function]

CONNECTION WITH EXTERNAL DEVICES

3.1 Signals required for accessing external devices

3.1 Signals required for accessing external devices

The functions and operations of the signals which are required for accessing the external devices are described below.

When connecting an external device that requires long access time, refer to sections “3.2 Software Wait,” “3.3 Ready function,” and “3.4 Hold function,” as well as this section. When the external DRAM is controlled by using DRAM controller, refer to “CHAPTER 14. DRAM CONTROLLER.”

3.1.1 Descriptions of signals

Figure 3.1.1 shows the pin configurations when the external data bus width is 16 bits and 8 bits.

(1) External buses (A_0 – A_7 , A_8/D_8 – A_{15}/D_{15} , A_{16}/D_0 – A_{23}/D_7)

The external area is specified by the address (A_0 – A_{23}) output.

The A_8 – A_{23} pins of the external address bus and the D_0 – D_{15} pins of the external data bus are assigned to the same pins.

When the BYTE pin level, described later, is “L” (external data bus width is 16 bits), the A_8/D_8 – A_{15}/D_{15} and A_{16}/D_0 – A_{23}/D_7 pins perform address output and data input/output with time-sharing.

When the BYTE pin level is “H” (external data bus width is 8 bits), the A_{16}/D_0 – A_{23}/D_7 pins perform address output and data input/output with time-sharing, and the A_8 – A_{15} pins output the address.

(2) External data bus width switching signal (BYTE pin level)

This signal is used to select the external data bus width from 8 bits and 16 bits. The width is 16 bits when the level is “L,” and 8 bits when the level is “H.” Fix this signal to either “H” or “L” level. This signal is valid only for the external area. (When accessing the internal area, the data bus width is always 16 bits.)

(3) Enable signal (\bar{E})

This signal becomes “L” level while reading or writing data from and to the data bus. (Refer to “Table 3.1.1.”)

(4) Read/Write signal (R/\bar{W})

This signal indicates the state of the data bus. This signal becomes “L” level while writing data to the data bus. Table 3.1.1 lists the state of the data bus indicated with the \bar{E} and R/\bar{W} signals.

Table 3.1.1 State of data bus indicated with \bar{E} and R/\bar{W} signals

\bar{E}	R/\bar{W}	State of data bus
H	H	Not used
	L	
L	H	Read data
	L	Write data

CONNECTION WITH EXTERNAL DEVICES

3.1 Signals required for accessing external devices

- External data bus width = 16 bits (BYTE = "L")

- External data bus width = 8 bits (BYTE = "H")

Note: For the DRAM control signals, refer to "CHAPTER 14. DRAM CONTROLLER."

Fig. 3.1.1 Pin configurations when external data bus width is 16 bits and 8 bits (top view)

CONNECTION WITH EXTERNAL DEVICES

3.1 Signals required for accessing external devices

(5) Byte low enable signal ($\overline{\text{BLE}}$), Byte high enable signal ($\overline{\text{BHE}}$)

The $\overline{\text{BLE}}$ signal indicates the access to an even address. This signal becomes “L” level when accessing only an even address or when simultaneously accessing both an even and an odd address. The $\overline{\text{BHE}}$ signal indicates the access to an odd address. This signal becomes “L” level when accessing only an odd address or when simultaneously accessing both an odd and an even address. These signals are used to connect memories or I/O devices of which data bus width is 8 bits when the external data bus width is 16 bits. Table 3.1.2 lists levels of the $\overline{\text{BLE}}$ and $\overline{\text{BHE}}$ signals and access addresses.

Table 3.1.2 Levels of $\overline{\text{BLE}}$ and $\overline{\text{BHE}}$ signals and access addresses

Access address	Even and odd addresses (Simultaneous 2-byte access)	Even address (1-byte access)	Odd address (1-byte access)
$\overline{\text{BLE}}$	L	L	H
$\overline{\text{BHE}}$	L	H	L

(6) Address latch enable signal (ALE)

This signal is used to latch the address from the multiplexed signal, which consists of the address and data. (This multiplexed signal is input to or output from the $A_8/D_8-A_{15}/D_{15}$ and $A_{16}/D_0-A_{23}/D_7$ pins.) When the ALE signal is “H,” latch the address and simultaneously output the addresses. When this signal is “L,” retain the latched address.

(7) Ready function-related signal ($\overline{\text{RDY}}$)

This is the signal to use Ready function (Refer to section “3.3 Ready function.”)

(8) Hold function-related signal ($\overline{\text{HOLD}}$)

This is the signal to use Hold function. (Refer to section “3.4 Hold function.”)

(9) Status signals (ST0, ST1)

These signals indicate the bus use status. Table 3.1.3 lists the bus use status indicated by the ST0 and ST1 signals.

(10) Clock ϕ_1

This signal has the same period as ϕ .

Table 3.1.3 Bus use status indicated by ST0 and ST1 signals

ST1	ST0	Bus use status
L	L	DRAM refresh
L	H	Hold
H	L	DMA
H	H	CPU

CONNECTION WITH EXTERNAL DEVICES

3.1 Signals required for accessing external devices

3.1.2 Operation of bus interface unit (BIU)

Figures 3.1.2 and 3.1.3 show the examples of operating waveforms of the signals input from or output to the external when accessing external devices. The following explains these waveforms, being compared with the basic operating waveform. (Refer to section “2.2.3 Operation of bus interface unit (BIU).”)

(1) When fetching instructions into instruction queue buffer

① When the instruction which is next fetched is located at an even address

When the external data bus width is 16 bits, the BIU fetches 2 bytes of the instruction at a time with waveform (a). When the external data bus width is 8 bits, the BIU fetches only 1 byte of the instruction with the first half of waveform (e).

② When the instruction which is next fetched is located at an odd address

When the external data bus width is 16 bits, the BIU fetches only 1 byte of the instruction with waveform (d). When the external data bus width is 8 bits, the BIU fetches only 1 byte of the instruction with the first half of waveform (f).

When a branch to an odd address is caused by a branch instruction etc. with the 16-bit external data bus width, the BIU first fetches 1 byte of the instruction with waveform (d), and after that, fetches instructions in a unit of 2 bytes with waveform (a).

(2) When reading or writing data from and to memories or I/O devices

① When accessing 16-bit data which begins at an even address, waveform (a) or (e) is applied.

② When accessing 16-bit data which begins at an odd address, waveform (b) or (f) is applied.

③ When accessing 8-bit data at an even address, waveform (c) or the first half of (e) is applied.

④ When accessing 8-bit data at an odd address, waveform (d) or the first half of (f) is applied.

For instructions that are affected by the data length flag (m) and the index register length flag (x), operation ① or ② is applied when flag m or x = “0”; operation ③ or ④ is applied when flag m or x = “1.”

The setup of flags m and x and the selection of the external data bus width do not affect each other.

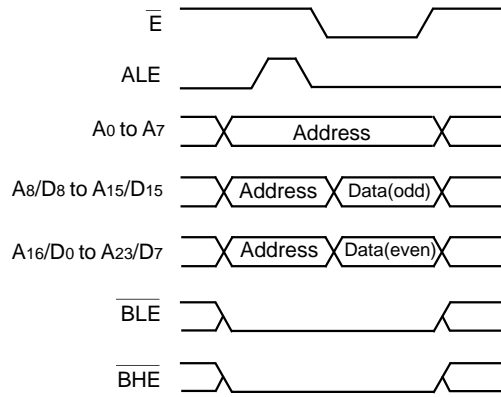

CONNECTION WITH EXTERNAL DEVICES

3.1 Signals required for accessing external devices

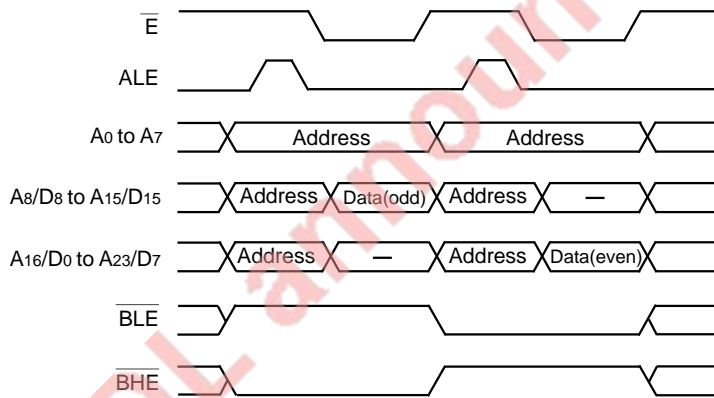

- External data bus width = 16 bits (BYTE = "L")

<16-bit data access>

(a) Access beginning at even address

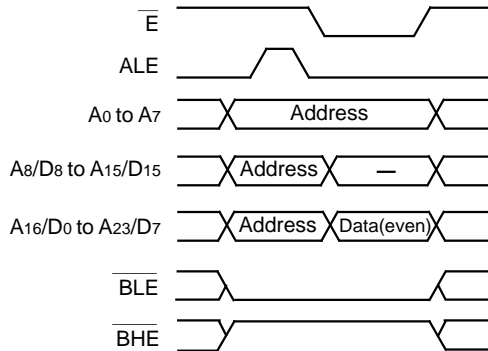

(b) Access beginning at odd address

<8-bit data access>

(c) Access to even address

(d) Access to odd address

- External data bus width = 8 bits (BYTE = "H")

<8/16-bit data access>

(e) Access beginning at even address

(f) Access beginning at odd address

Note: When accessing 16-bit data, 2 times of access are performed; the low-order 8 bits are accessed first, and after that, the high-order 8 bits are accessed.

Fig. 3.1.3 Examples of operating waveforms of signals input from or output to the external (2)

CONNECTION WITH EXTERNAL DEVICES

3.2 Software Wait

3.2 Software Wait

Software Wait provides a function to facilitate access to external devices that require long access time. To select the software Wait, use the wait bit (bit 2 at address 5E₁₆). Figure 3.2.1 shows the structure of processor mode register 0 (address 5E₁₆). Figure 3.2.2 shows examples of bus timing when software Wait is used.

Software Wait is valid only for the external area. The internal area is always accessed with no Wait.

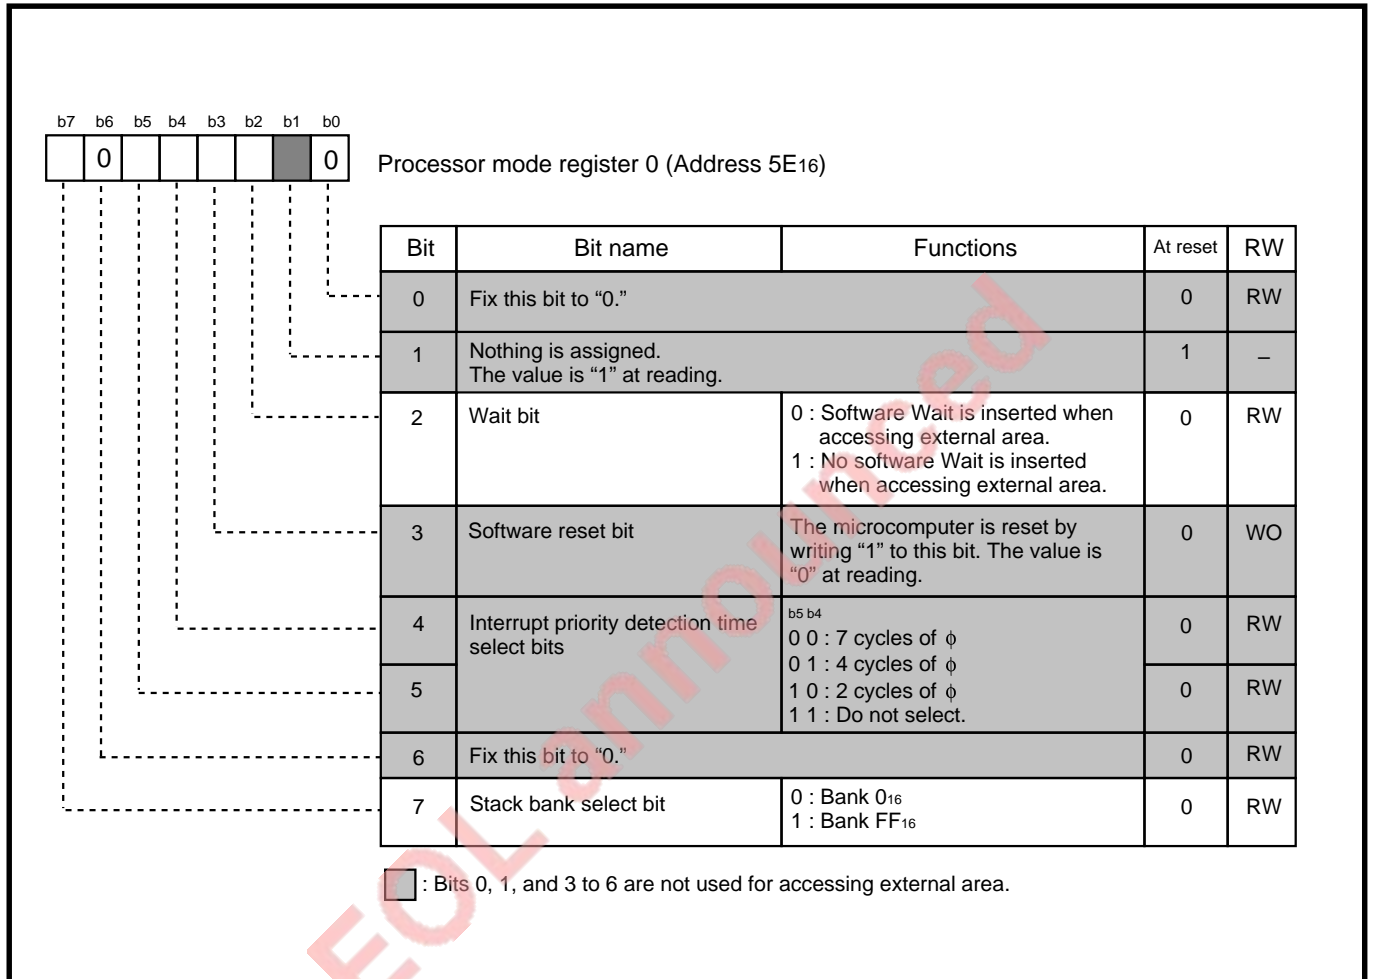

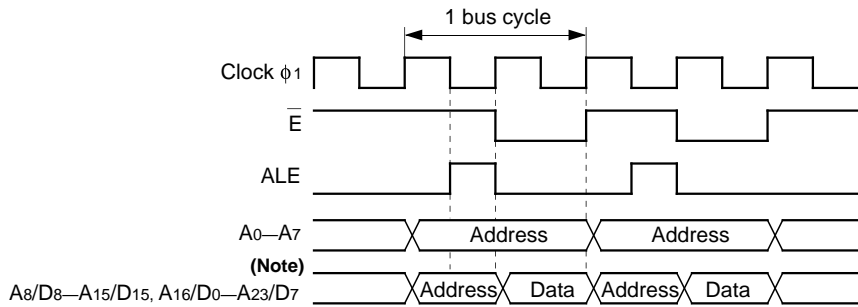

Fig. 3.2.1 Structure of processor mode register 0

<No Wait>

● Internal areas are always accessed with this waveform.

<Wait>

Note: When the external data bus is 8 bits wide (BYTE = "H"), A₈/D₈ to A₁₅/D₁₅ operate with the same bus timing as A₀ to A₇.

Fig. 3.2.2 Examples of bus timing when software Wait is used (BYTE = "L")

CONNECTION WITH EXTERNAL DEVICES

3.3 Ready function

3.3 Ready function

Ready function provides the function to facilitate access to external devices that require long access time. The microcomputer enters Ready state by input of "L" level to the RDY pin and retains this state while the level of the RDY pin is at "L." Table 3.3.1 lists the microcomputer's state in Ready state.

In Ready state, the oscillator's oscillation does not stop. Accordingly, the internal peripheral devices can operate. Ready function is valid for the internal and external areas.

Table 3.3.1 Microcomputer's state in Ready state

Item	State
Oscillation	Operating
ϕ_{CPU} , ϕ	Stopped at "L"
Pins A_0 to A_7 , A_8/D_8 to A_{15}/D_{15} , A_{16}/D_0 to A_{23}/D_7 , \bar{E} , R/\bar{W} , \bar{BHE} , \bar{BLE} , ST_0 , ST_1 , ALE	Retain the state when Ready request was accepted.
Pins P_{4_3} to P_{4_7} , P_5 to P_{10} (Note)	
Pin ϕ_1	Outputs clock ϕ_1 .
Watchdog timer	Operating

Note: This applies when this functions as a programmable I/O port.

EOL announced

CONNECTION WITH EXTERNAL DEVICES

3.3 Ready function

3.3.1 Operation description

The input level of the $\overline{\text{RDY}}$ pin is judged at the falling edge of clock ϕ_1 . When "L" level is detected at this point, the microcomputer enters Ready state. (This is called "Acceptance of Ready request.")

In Ready state, the input level of the $\overline{\text{RDY}}$ pin is judged at every falling edge of clock ϕ_1 . When "H" level is detected at this point, the microcomputer terminates Ready state at the next rising edge of clock ϕ_1 .

Figure 3.3.1 shows timing of acceptance of Ready request and termination of Ready state. Refer also to section "16.1 Memory connection" for usage of Ready function.

Fig. 3.3.1 Timing of acceptance of Ready request and termination of Ready state

CONNECTION WITH EXTERNAL DEVICES

3.4 Hold function

3.4 Hold function

When composing the external circuit which accesses the bus without using the central processing unit (CPU), Hold function is used to generate a timing for transferring the right to use the bus from the CPU to the external circuit.

The microcomputer enters Hold state by input of "L" level to the $\overline{\text{HOLD}}$ pin and retains this state while the level of the $\overline{\text{HOLD}}$ pin is at "L." Table 3.4.1 lists the microcomputer's state in Hold state.

In Hold state, the oscillation of the oscillator does not stop. Accordingly, the internal peripheral devices can operate. However, Watchdog timer stops operating.

Table 3.4.1 Microcomputer's state in Hold state

Item	State
Oscillation	Operating
ϕ	Operating
ϕ_{CPU}	Stopped at "L"
$\overline{\text{E}}$	Stopped at "H"
Pins A_0 to A_7 , A_8/D_8 to $\text{A}_{15}/\text{D}_{15}$, A_{16}/D_0 to A_{23}/D_7 , $\text{R}/\overline{\text{W}}$, $\overline{\text{BHE}}$, $\overline{\text{BLE}}$	Floating
Pins ALE , ST_1	Output "L" level.
Pin ST_0	Outputs "H" level.
Pin ϕ_1	Outputs clock ϕ_1 .
Pins P_{4_3} to P_{4_7} , P_5 to P_{10} (Note)	Retain the state when Hold request was accepted.
Watchdog timer	Stopped

Note: This applies when this functions as a programmable I/O port.

3.4.1 Operation description

Judgment of the $\overline{\text{HOLD}}$ pin input level is performed at every falling edge of ϕ_1 . When "L" level is detected at judgment of the input level, bus request (Hold) becomes "1," when "H" level is detected, bus request (Hold) becomes "0."

Bus request (Hold) is sampled within a period when the bus request sampling signal is "1" and bus request is accepted when there is no bus request (DRAMC). (This is called "Acceptance of Hold request.") For bus request, refer to section "13.2.1 Bus access control circuit."

When Hold request is accepted, ϕ_{CPU} stops at "L" level at the next rising edge of ϕ and the ST_0 pin's level becomes "H," the ST_1 pin's level becomes "L." When 1 cycle of ϕ has passed after the levels of the ST_0 and ST_1 pins are changed, the $\text{R}/\overline{\text{W}}$, $\overline{\text{BHE}}$, $\overline{\text{BLE}}$ pins and the external bus enter the floating state.

In Hold state, when the $\overline{\text{HOLD}}$ pin's input level becomes "H," the ST_0 and ST_1 pins' levels are changed at the next rising edge of ϕ . When 1 cycle of ϕ has passed after the levels of the ST_0 and ST_1 pins are changed, the microcomputer terminates Hold state.

Figures 3.4.1 to 3.4.3 show timing of acceptance of Hold request and termination of Hold state.

Note: ϕ has the same polarity and the same frequency as clock ϕ_1 .

However, ϕ stops by acceptance of Ready request, or executing the **STP** or **WIT** instruction. Accordingly, judgment of the input level of the $\overline{\text{HOLD}}$ pin is not performed during Ready state.

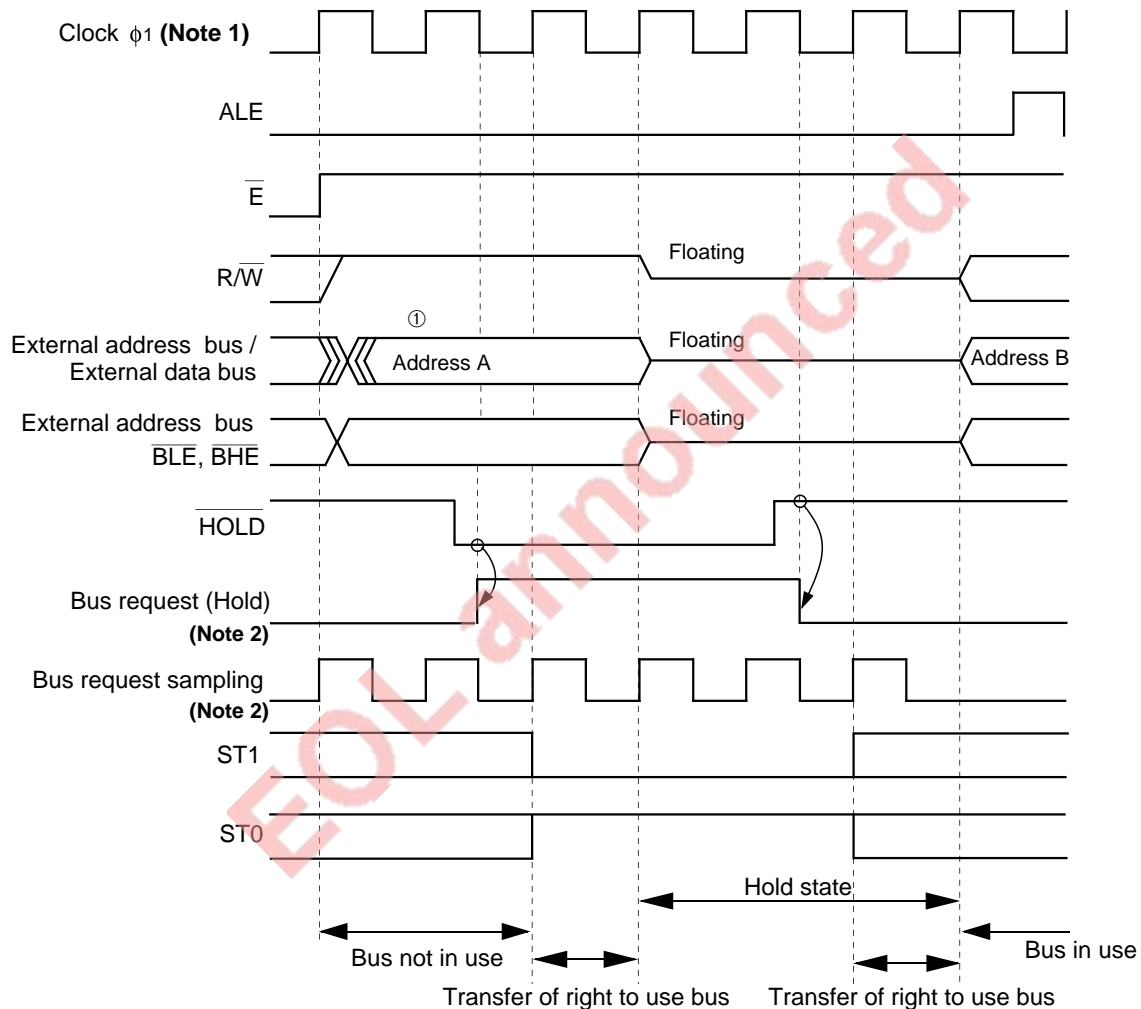

CONNECTION WITH EXTERNAL DEVICES

3.4 Hold function

<When inputting "L" level to $\overline{\text{HOLD}}$ pin while bus is unused>

● State when inputting "L" level to $\overline{\text{HOLD}}$ pin

External data bus	Data length	External data bus width
Unused	8	8, 16
	16	8, 16

① This is the period in which the bus is not used, so that not a new address but the address which was output immediately before is output again.

Notes 1: Clock ϕ_1 has the same polarity and the same frequency as ϕ .
Timing of signals to be input from or output to the external is ordained on the basis of clock ϕ_1 .

2: Bus request (Hold) and bus request sampling are internal signals.

Fig. 3.4.1 Timing of acceptance of Hold request and termination of Hold state (1)

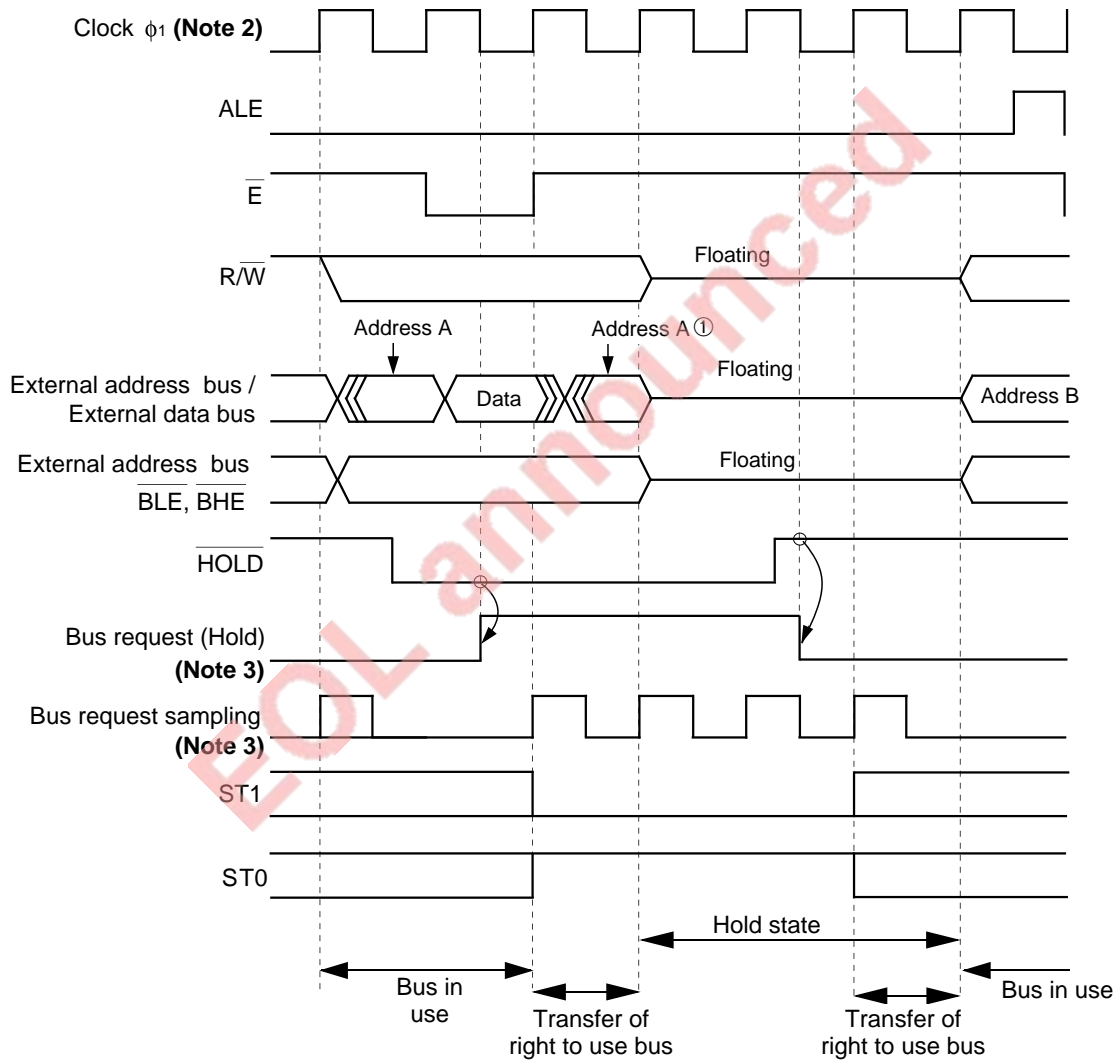

CONNECTION WITH EXTERNAL DEVICES

3.4 Hold function

<When inputting “L” level to $\overline{\text{HOLD}}$ pin while bus is used; when data access is completed with 1-bus cycle>

● State when inputting “L” level to $\overline{\text{HOLD}}$ pin

External data bus	Data length	External data bus width
Used	8	8, 16
	16	16 (Access beginning at even address)

① When a Hold request is accepted, not a new address but the address which was output immediately before is output again.

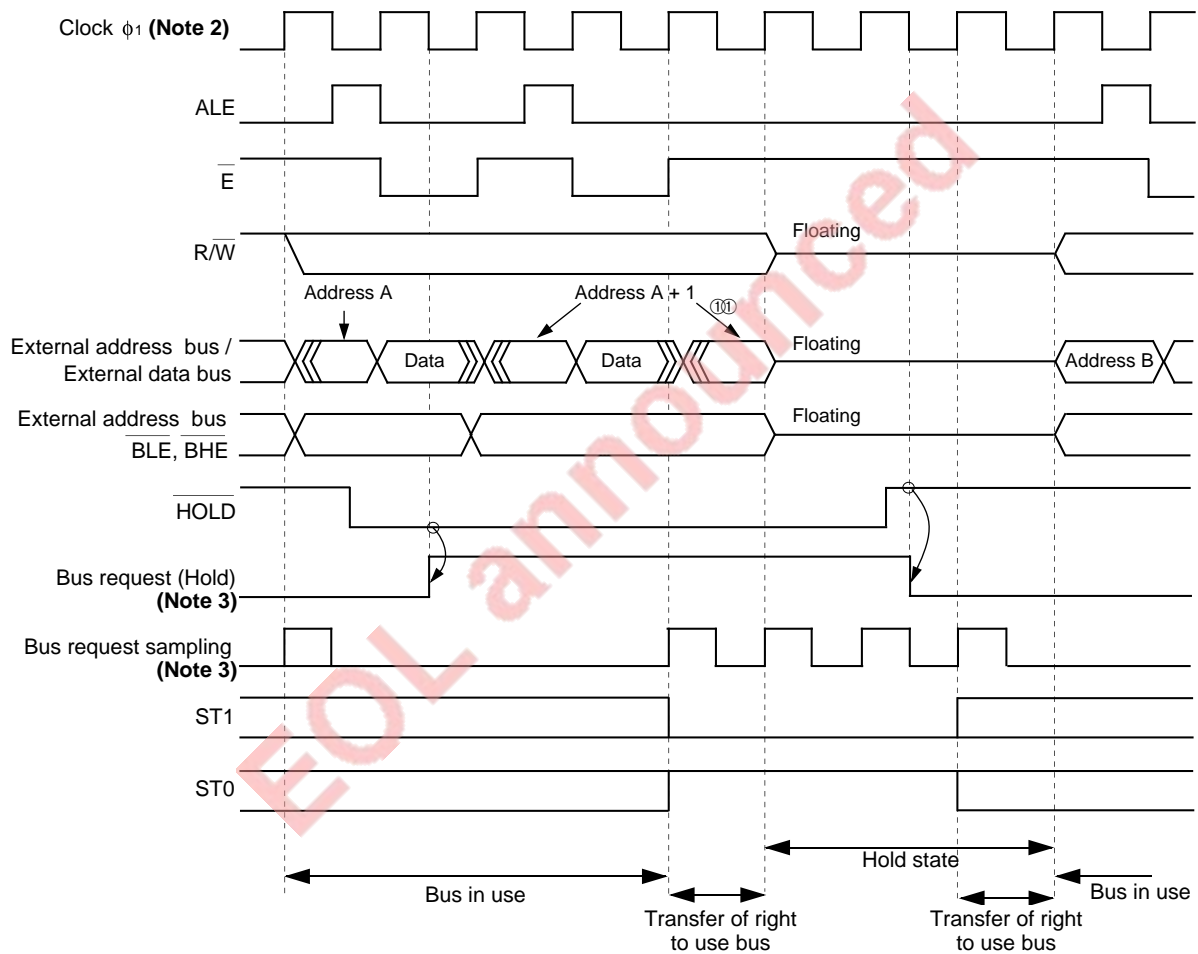

- Notes 1:** The above diagram shows the case of no Wait.
2: Clock ϕ_1 has the same polarity and the same frequency as ϕ .
 Timing of signals to be input from or output to the external is ordained on the basis of clock ϕ_1 .
3: Bus request (Hold) and bus request sampling are internal signals.

Fig. 3.4.2 Timing of acceptance of Hold request and termination of Hold state (2)

<When inputting "L" level to $\overline{\text{HOLD}}$ pin while bus is used; when data access is completed with continuous 2-bus cycle>

● State when inputting "L" level to $\overline{\text{HOLD}}$ pin

External data bus	Data length	External data bus width
Used	16	8
		16 (Access beginning at odd address)

① When a Hold request is accepted, not a new address but the address which was output immediately before is output again.

Notes 1: The above diagram shows the case of 2- ϕ access in low-speed running.

2: Clock ϕ_1 has the same polarity and the same frequency as ϕ .

Timing of signals to be input from or output to the external is ordained on the basis of clock ϕ_1 .

3: Bus request (Hold) and bus request sampling are internal signals.

Fig. 3.4.3 Timing of acceptance of Hold request and termination of Hold state (3)

CONNECTION WITH EXTERNAL DEVICES

3.4 Hold function

[Precautions for Hold function]

When a DRAM refresh request occurs in Hold state, DRAM refresh is performed immediately because the bus use priority level of DRAM refresh is higher than that of Hold function.

EOL announced

CHAPTER 4

RESET

RESET

4.1 Hardware reset

4.1 Hardware reset

When the power source voltage satisfies the microcomputer's recommended operating conditions, the microcomputer is reset by supplying "L" level to the $\overline{\text{RESET}}$ pin. This is called a hardware reset. Figure 4.1.1 shows an example of hardware reset timing.

Fig. 4.1.1 Example of hardware reset timing

The following explains how the microcomputer operates in periods ① to ④ above.

- ① After supplying "L" level to the $\overline{\text{RESET}}$ pin, the microcomputer initializes pins within a period of several ten ns. (Refer to "Table 4.1.1.")
- ② While the $\overline{\text{RESET}}$ pin is "L" level and within a period of 4 to 5 cycles of ϕ after the $\overline{\text{RESET}}$ pin goes from "L" to "H," the microcomputer initializes the central processing unit (CPU) and SFR area. At this time, the contents of the internal RAM area become undefined (except when Stop or Wait mode is terminated). (Refer to "Figures 4.1.3 to 4.1.9.")
- ③ After ②, the microcomputer performs "Internal processing sequence after reset." (Refer to "Figure 4.1.10.")
- ④ The microcomputer executes a program beginning with the address set into the reset vector addresses (FFFE_{16} and FFFF_{16}).

4.1.1 Pin state

Table 4.1.1 lists the microcomputer's pin state while $\overline{\text{RESET}}$ pin is at "L" level. Figure 4.1.2 shows the $\overline{\text{RESET}}_{\text{OUT}}$ output retaining timing.

Table 4.1.1 Pin state while $\overline{\text{RESET}}$ pin is at "L" level

Pin (Bus, Port) name	Pin state
$A_0/\overline{\text{MA}}_0\text{--}A_7/\overline{\text{MA}}_7$, $A_8/\overline{\text{D}}_8\text{--}A_{15}/\overline{\text{D}}_{15}$, $A_{16}/\overline{\text{D}}_0\text{--}A_{23}/\overline{\text{D}}_7$, $\overline{\text{BHE}}$, $\overline{\text{BLE}}$	Outputs "H" or "L" level.
$\overline{\text{R}}/\overline{\text{W}}$, $\overline{\text{E}}$, ST_0 , ST_1	Outputs "H" level.
ALE , $\overline{\text{RESET}}_{\text{OUT}}$	Outputs "L" level.
ϕ_1	Outputs ϕ_1 .
$\overline{\text{HOLD}}$, $\overline{\text{RDY}}$, $\text{P}_{43}\text{--}\text{P}_{47}$, $\text{P}_5\text{--}\text{P}_{10}$	Floating.

Fig. 4.1.2 $\overline{\text{RESET}}_{\text{OUT}}$ output retaining timing

RESET

4.1 Hardware reset

4.1.2 State of CPU, SFR area, and internal RAM area

Figure 4.1.3 shows the state of the CPU registers immediately after reset. Figures 4.1.4 to 4.1.9 show the state of the SFR and internal RAM areas immediately after reset.

Fig. 4.1.3 State of CPU registers immediately after reset

●SFR area (016 to 7F16, 1FC016 to 1FFF16)

Access characteristics

RW: It is possible to read the bit state at reading. The written value becomes valid.

RO : It is possible to read the bit state at reading. The written value becomes invalid.

WO : The written value becomes valid. It is impossible to read the bit state.

□ : Nothing is assigned. It is impossible to read the bit state. The written value becomes invalid.

State immediately after reset

0 : "0" immediately after reset.

1 : "1" immediately after reset.

? : Undefined immediately after reset.

0 : Always "0" at reading.

1 : Always "1" at reading.

? : Always undefined at reading.

0 : "0" immediately after reset. Fix this bit to "0."

 - At software reset..... Retains the state immediately before reset
 - At termination of Stop or Wait mode (Hardware reset is used to terminate it.)..... Retains the state immediately before the **STP** or **WIT** instruction is executed

* For the M37721S2BFP, the internal RAM area can be assigned to addresses 80₁₆ to 47F₁₆ by setting the internal RAM area select bit (bit 1 at address 5F₁₆). (Refer to section “2.4 Memory assignment.”)

Fig. 4.1.9 State of SFR and internal RAM areas immediately after reset (6)

4.1.3 Internal processing sequence after reset

Figure 4.1.10 shows the internal processing sequence after reset.

Fig. 4.1.10 Internal processing sequence after reset

RESET

4.1 Hardware reset

4.1.4 Time supplying “L” level to $\overline{\text{RESET}}$ pin

Time supplying “L” level to the $\overline{\text{RESET}}$ pin varies according to the state of the clock oscillation circuit.

- When the oscillator is stably oscillating or a stable clock is input from the X_{IN} pin, supply “L” level for $2 \mu\text{s}$ or more.
 - When the oscillator is not stably oscillating (including the case at power-on reset or in Stop mode), supply “L” level until the oscillation is stabilized.
- The time required for stabilizing oscillation varies according to the oscillator. For details, contact the oscillator manufacturer.

Figure 4.1.11 shows the power-on reset conditions. Figure 4.1.12 shows an example of a power-on reset circuit.

* For details about Stop mode, refer to section “5.3 Stop mode.” For details about clocks, refer to “CHAPTER 5. CLOCK GENERATING CIRCUIT.”

Fig. 4.1.11 Power-on reset conditions

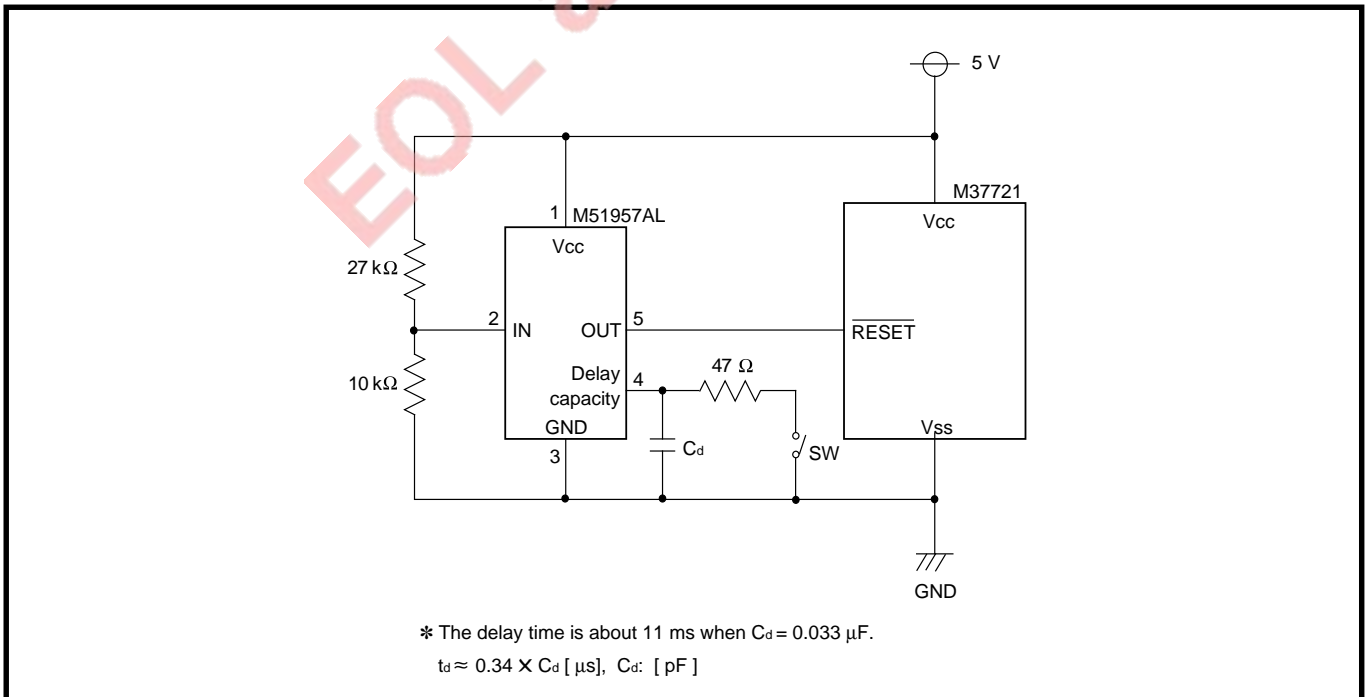

Fig. 4.1.12 Example of power-on reset circuit

4.2 Software reset

When the power source voltage satisfies the microcomputer's recommended operating conditions, the microcomputer is reset by writing "1" to the software reset bit (bit 3 at address 5E₁₆). (This is called "Software reset.") In this case, the microcomputer initializes pins, CPU, and SFR area just as in the case of a hardware reset. However, the microcomputer retains the contents of the internal RAM area. (Refer to "Table 4.1.1" and "Figures 4.1.3 to 4.1.9.") Figure 4.2.1 shows the structure of the processor mode register 0 (address 5E₁₆).

After completing initialization, the microcomputer performs "internal processing sequence after reset." (Refer to "Figure 4.1.10.") After that, it executes a program beginning from the address set into the reset vector addresses (FFFE₁₆ and FFFF₁₆).

Fig. 4.2.1 Structure of processor mode register 0

RESET

4.2 Software reset

When the software reset bit is set to “1,” the $\overline{\text{RESET}}_{\text{OUT}}$ pin’s output level becomes “L.” In a period of 4.5 cycles of clock ϕ_1 after the software reset bit is set to “1,” the $\overline{\text{RESET}}_{\text{OUT}}$ pin’s output level is “L.” Figure 4.2.2 shows the $\overline{\text{RESET}}_{\text{OUT}}$ output timing at software reset.

Fig. 4.2.2 $\overline{\text{RESET}}_{\text{OUT}}$ output timing

CLOCK GENERATING CIRCUIT

5.1 Oscillation circuit examples

5.1 Oscillation circuit examples

To the oscillation circuit, a ceramic resonator or a quartz-crystal oscillator can be connected, or the clock which is externally generated can be input. Oscillation circuit examples are shown below.

5.1.1 Connection example using resonator/oscillator

Figure 5.1.1 shows an example when connecting a ceramic resonator/quartz-crystal oscillator between pins X_{IN} and X_{OUT} .

The circuit constants such as R_f , R_d , C_{IN} , and C_{OUT} (shown in “Figure 5.1.1”) depend on the resonator/oscillator. These values shall be set to the values recommended by the resonator/oscillator manufacturer.

5.1.2 Externally generated clock input example

Figure 5.1.2 shows an input example of the clock which is externally generated. The external clock must be input from the X_{IN} pin, and the X_{OUT} pin must be left open.

Fig. 5.1.1 Connection example using resonator/oscillator

Fig. 5.1.2 Externally generated clock input example

5.2 Clocks

Figure 5.2.1 shows the clock generating circuit block diagram.

Fig. 5.2.1 Clock generating circuit block diagram

CLOCK GENERATING CIRCUIT

5.2 Clocks

5.2.1 Clocks generated in clock generating circuit

(1) ϕ

It is the operation clock of BIU. It is also the clock source of ϕ_{CPU} . ϕ stops by acceptance of Ready request or execution of the **STP** or **WIT** instruction. It is not stopped by acceptance of bus request.

(2) ϕ_{CPU}

It is the operation clock of CPU. ϕ_{CPU} stops by the following:

- Execution of the **STP** or **WIT** instruction,
- Acceptance of Ready request; "L" level input to the \overline{RDY} pin
- CPU wait request from BIU; Acceptance of bus request is included.

(3) **Clock** ϕ_1

It has the same period as ϕ and is output to the external from the ϕ_1 pin. Clock ϕ_1 stops by execution of the **STP** instruction.

It is not stopped by acceptance of Ready or bus request, or execution of the **WIT** instruction.

(4) f_2 to f_{512}

Each of them is the internal peripheral devices' operation clock.

Note: Refer to each functional description for details:

- Execution of **STP** instruction "5.3 Stop mode"
- Execution of **WIT** instruction "5.4 Wait mode"
- Ready "3.3 Ready function"
- Bus request "13.2.1 Bus access control circuit"

CLOCK GENERATING CIRCUIT

5.3 Stop mode

5.3 Stop mode

Stop mode is used to stop oscillation when there is no need to operate the central processing unit (CPU). The microcomputer enters Stop mode when the **STP** instruction is executed.

Stop mode can be terminated by an interrupt request occurrence or the hardware reset.

5.3.1 Stop mode

When the **STP** instruction is executed, the oscillator stops oscillating. This state is called "Stop mode." In Stop mode, the contents of the internal RAM can be retained intact when V_{CC} (power source voltage) is 2 V or more. Additionally, the microcomputer's power consumption is lowered. It is because the CPU and all internal peripheral devices using clocks f_2 to f_{512} stop the operation.

Table 5.3.1 lists the microcomputer's state and operation in and after Stop mode.

Table 5.3.1 Microcomputer's state and operation in and after Stop mode

Item		State and Operation
State in Stop mode	Oscillation	Stopped
	ϕ_{CPU} , ϕ	
	Clock ϕ_1 , f_2 to f_{512}	
Internal peripheral devices	Timers A, B	Can operate only in event counter mode
	Serial I/O	Can operate only when an external clock is selected
	A-D converter	Stopped
	DMA controller	
	DRAM controller	
	Watchdog timer	Stopped
	Pins	Retains the same state in which the STP instruction was executed
Operation after terminating Stop mode	By interrupt request occurrence	Supply of ϕ_{CPU} and ϕ starts after a certain time measured by Watchdog timer has passed.
	By hardware reset	Operates in the same way as hardware reset

Note: DRAM refresh is not performed because the refresh timer also stops.

CLOCK GENERATING CIRCUIT

5.3 Stop mode

(1) Termination by interrupt request occurrence

When terminating Stop mode by interrupt request occurrence, instructions are executed after a certain time measured by the watchdog timer has passed.

- ① When an interrupt request occurs, the oscillator starts oscillating. Simultaneously, supply of clock ϕ_1 , f_2 to f_{512} starts.
- ② The watchdog timer starts counting owing to the oscillation start. The watchdog timer counts f_{32} regardless of the watchdog timer frequency select bit's (bit 0 at address 61_{16}) contents.
- ③ When the watchdog timer's MSB becomes "0," supply of ϕ_{CPU} and ϕ starts. At the same time, the watchdog timer's count source returns to f_{32} or f_{512} that is selected by the watchdog timer frequency select bit.
- ④ The interrupt request which occurred in ① is accepted.

Table 5.3.2 lists the interrupts used to terminate Stop mode.

Table 5.3.2 Interrupts used to terminate Stop mode

Interrupt	Conditions for using each function to generate interrupt request
INTi interrupt (i = 0 to 2)	
Timer Ai interrupt (i = 2 to 4)	In event counter mode
Timer Bi interrupt (i = 0, 1)	
UARTi transmit interrupt (i = 0, 1)	When external clock is selected
UARTi receive interrupt (i = 0, 1)	

Notes 1: Since the oscillator has stopped oscillating, interrupts not listed above cannot be used. Also, even the interrupts listed above cannot be used when the above conditions are not satisfied. The A-D converter does not operate, also.

2: When multiple interrupts listed above are enabled, Stop mode is terminated by the interrupt request which occurs first.

3: Refer to "**CHAPTER 7. INTERRUPTS**" and the description of each internal peripheral device for details about each interrupt.

Before executing the **STP** instruction, interrupts used to terminate Stop mode must be enabled.

In addition, the interrupt priority level of the interrupt used to terminate Stop mode must be higher than the processor interrupt priority level (IPL) of the routine where the **STP** instruction is executed. When multiple interrupts in Table 5.3.2 are enabled, Stop mode is terminated by the first interrupt request.

There is a possibility that any of all interrupt requests occurs after the oscillation starts in ① and until supply of ϕ_{CPU} and ϕ starts in ③. The interrupt requests which occur during this period are accepted in order of priority after the watchdog timer's MSB becomes "0."

For interrupts not to be accepted, set their interrupt priority levels to level 0 (interrupt disabled) before executing the **STP** instruction.

CLOCK GENERATING CIRCUIT

5.3 Stop mode

Fig. 5.3.1 Stop mode terminating sequence by interrupt request occurrence

(2) Termination by hardware reset

Supply "L" level to the RESET pin by using the external circuit until the oscillation of the oscillator is stabilized.

The CPU and the SFR area are initialized in the same way as system reset. However, the internal RAM area retains the same contents as that before executing the STP instruction. The terminating sequence is the same as the internal processing sequence which is performed after reset.

Refer to "CHAPTER 4. RESET" for details about reset.

CLOCK GENERATING CIRCUIT

5.3 Stop mode

[Precautions for Stop mode]

When executing the **STP** instruction after writing to an internal area or an external area, three **NOP** instructions must be inserted to complete the write operation before the **STP** instruction is executed. (Refer to “**Figure 5.3.2.**”)

```
STA A, XXXX ; Write instruction
NOP          ; NOP instruction inserted
NOP          ;
NOP          ;
STP          ; STP instruction
```

Fig. 5.3.2 NOP instruction insertion example

EOL announced

CLOCK GENERATING CIRCUIT

5.4 Wait mode

5.4 Wait mode

Wait mode is used to stop ϕ_{CPU} and ϕ when there is no need to operate the central processing unit (CPU). The microcomputer enters Wait mode when the **WIT** instruction is executed.

Wait mode can be terminated by an interrupt request occurrence or the hardware reset.

5.4.1 Wait mode

When the **WIT** instruction is executed, ϕ_{CPU} and ϕ stop. The oscillator's oscillation is not stopped. This state is called "Wait mode."

In Wait mode, the microcomputer's power consumption is lowered though V_{CC} (power source voltage) is maintained.

Table 5.4.1 lists the microcomputer's state and operation in and after Wait mode.

Table 5.4.1 Microcomputer's state and operation in and after Wait mode

Item		State and Operation	
State in Wait mode	Oscillation	Operating	
	ϕ_{CPU} , ϕ	Stopped	
	Clock ϕ_1 , f_2 to f_{512}	Operating	
	Internal peripheral devices	Timer A	Operating
		Timer B	
		Serial I/O	
		A-D converter	
		DMA controller	Stopped
		DRAM controller	Stopped (Note)
Watchdog timer		Operating	
Pins	Retains the same state in which the WIT instruction was executed		
Operation after terminating Wait mode	By interrupt request occurrence	Supply of ϕ_{CPU} and ϕ starts just after the termination.	
	By hardware reset	Operates in the same way as hardware reset.	

Note: The refresh timer operates, but DRAM refresh is not performed because the bus request (DRAMC) does not occur. (Refer to section "**Appendix 9. 7721 Group Q & A.**")

CLOCK GENERATING CIRCUIT

5.4 Wait mode

(1) Termination by interrupt request occurrence

- ① When an interrupt request occurs, supply of ϕ_{CPU} and ϕ starts.
- ② The interrupt request which occurred in ① is accepted.

The following interrupts are used to terminate Wait mode.

When a watchdog timer interrupt request occurs, Wait mode is also terminated.

- $\overline{\text{INT}}_i$ interrupt ($i = 0$ to 2)
- Timer A_i interrupt ($i = 0$ to 4)
- Timer B_i interrupt ($i = 0$ to 2)
- UART $_i$ transmit interrupt ($i = 0, 1$)
- UART $_i$ receive interrupt ($i = 0, 1$)
- A-D converter interrupt

Note: Refer to “CHAPTER 7. INTERRUPTS” and each functional description about interrupts.

Before executing the **WIT** instruction, interrupts used to terminate Wait mode must be enabled.

In addition, the interrupt priority level of the interrupt used to terminate Wait mode must be higher than the processor interrupt priority level (IPL) of the routine where the **WIT** instruction is executed. When multiple interrupts listed above are enabled, Wait mode is terminated by the interrupt request which occurs first.

(2) Termination by hardware reset

The CPU and the SFR area are initialized in the same way as system reset. However, the internal RAM area retains the same contents as that before executing the **WIT** instruction. The terminating sequence is the same as the internal processing sequence which is performed after reset.

Refer to “CHAPTER 4. RESET” for details about reset.

[Precautions for Wait mode]

When executing the **WIT** instruction after writing to an internal area or an external area, three **NOP** instructions must be inserted to complete the write operation before the **WIT** instruction is executed. (Refer to “**Figure 5.4.1.**”)

```
STA  A, XXXX ; Write instruction
NOP           ; NOP instruction inserted
NOP           ;
NOP           ;
WIT          ; WIT instruction
```

INPUT/OUTPUT PINS

- 6.1 Overview
- 6.2 Programmable I/O ports
- 6.3 Examples of handling unused pins

EOL announced

INPUT/OUTPUT PINS

6.1 Overview, 6.2 Programmable I/O ports

6.1 Overview

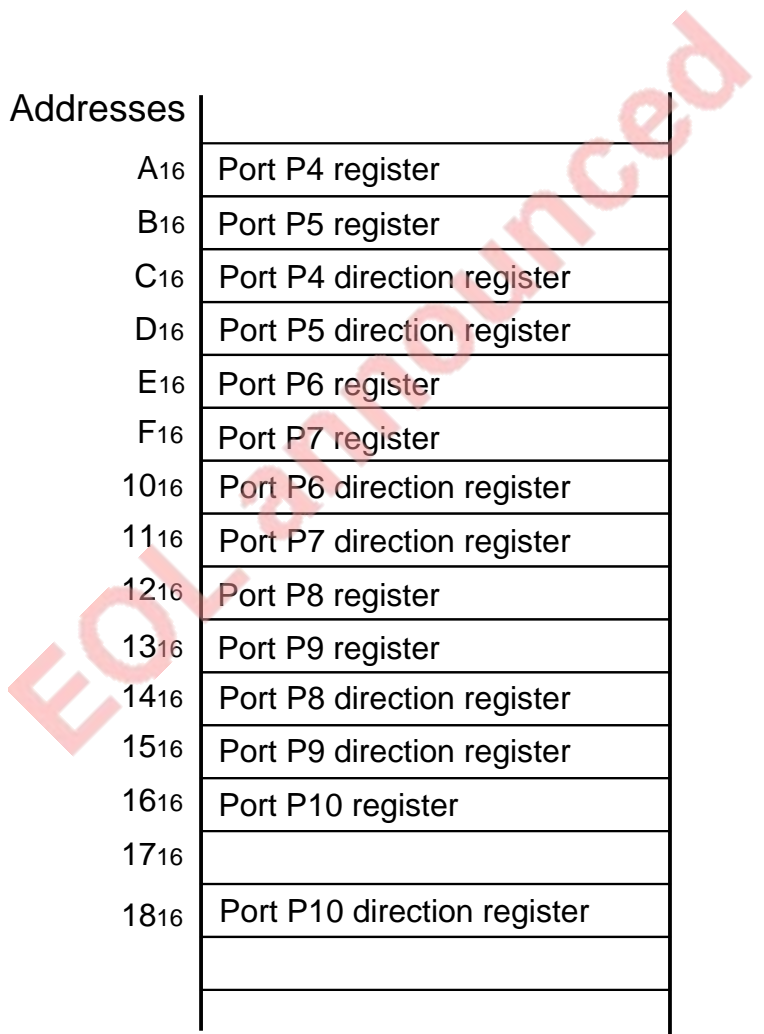

Input/output pins (hereafter called I/O pins) have functions as programmable I/O ports, internal peripheral devices's I/O pins, external buses, etc.

For the basic functions of each I/O pin, refer to section "1.3 Pin description." For the I/O functions of the internal peripheral devices, refer to relevant sections of each internal peripheral device. For the external address bus, external data bus, bus control signals, etc., refer to "CHAPTER 3. CONNECTION WITH EXTERNAL DEVICES."

This chapter describes the programmable I/O ports and examples of handling unused pins.

6.2 Programmable I/O ports

The programmable I/O ports have direction registers and port registers in the SFR area. Figure 6.2.1 shows the memory map of direction registers and port registers.

Addresses	
A ₁₆	Port P4 register
B ₁₆	Port P5 register
C ₁₆	Port P4 direction register
D ₁₆	Port P5 direction register
E ₁₆	Port P6 register
F ₁₆	Port P7 register
10 ₁₆	Port P6 direction register
11 ₁₆	Port P7 direction register
12 ₁₆	Port P8 register
13 ₁₆	Port P9 register
14 ₁₆	Port P8 direction register
15 ₁₆	Port P9 direction register
16 ₁₆	Port P10 register
17 ₁₆	
18 ₁₆	Port P10 direction register

Fig. 6.2.1 Memory map of direction registers and port registers

INPUT/OUTPUT PINS

6.2 Programmable I/O ports

6.2.1 Direction register

This register determines the I/O direction of programmable I/O ports. Each bit of this register corresponds one for one to each pin of the microcomputer.

Figure 6.2.2 shows the structure of port Pi (i = 4 to 10) direction register.

Fig. 6.2.2 Structure of port Pi (i = 4 to 10) direction register

INPUT/OUTPUT PINS

6.2 Programmable I/O ports

6.2.2 Port register

Data is input from or output to the external by writing/reading data to/from a port register. A port register consists of a port latch which holds the output data and a circuit which reads the pin state. Each bit of the port register corresponds one for one to each pin of the microcomputer. Figure 6.2.3 shows the structure of the port Pi (i = 4 to 10) register.

- **When outputting data from programmable I/O port set to output mode**

- ① By writing data to the corresponding bit of the port register, the data is written into the port latch.
- ② The data is output from the pin according to the contents of the port latch.

By reading the port register of a port set to the output mode, the contents of the port latch is read out, instead of the pin state. Accordingly, the output data is correctly read without being affected by an external load, etc. (Refer to “**Figures 6.2.4 and 6.2.5.**”)

- **When inputting data from programmable I/O port set to input mode**

- ① A pin which is set to the input mode enters the floating state.
- ② By reading the corresponding bit of the port register, the data which is input from the pin can be read out.

By writing data to the port register of a programmable I/O port set to the input mode, the data is written only into the port latch and is not output to the external (**Note**). The pin remains floating.

Note: When executing a read-modify-write instruction (**CLB, SEB, INC, DEC, ASL, ASR, LSR, ROL, ROR**) to the port register of a programmable I/O port set to the input mode, the instruction is executed to the data which is input from the pin and the result is written into the port register.

INPUT/OUTPUT PINS

6.3 Examples of handling unused pins

6.3 Examples of handling unused pins

When unusing an I/O pin, some handling is necessary for the pin. Examples of handling unused pins are described below.

The following are just examples. The user shall modify them according to the user's actual application and test them.

Table 6.3.1 Examples of handling unused pins

Pin name	Handling example
P4 ₃ to P4 ₇ , P5 to P10	Set these pins to the input mode and connect each pin to Vcc or Vss via a resistor; or set these pins to the output mode and leave them open (Notes 1 and 2).
\overline{BLE} , \overline{BHE} , ALE, ϕ_1 , ST0, ST1	Leave them open.
X _{OUT} (Note 3)	
HOLD, RDY	Connect these pins to Vcc via a resistor (pull-up) (Note 2).
CNV _{ss}	Connect this pin to Vcc or Vss.
AVcc	Connect this pin to Vcc.
AVss, V _{REF}	Connect these pins to Vss.

Notes 1: When leaving these pins open after they are set to the output mode, note the following: these pins function as input ports from reset until they are switched to the output mode by software. Therefore, voltage levels of these pins are undefined and the power source current may increase while these pins function as input ports. After reset, immediately set these ports to the output mode.

Software reliability can be enhanced by setting the contents of the above ports' direction registers periodically. This is because these contents may be changed by noise, a program runaway which occurs owing to noise, etc.

2: For unused pins, use the shortest possible wiring (within 20 mm from the microcomputer's pins).

3: This applies when a clock externally generated is input to the X_{IN} pin.

- 7.11 Precautions for interrupts

INTERRUPTS

7.1 Overview

7.1 Overview

The M37721 provides 23 interrupt sources to generate interrupt requests.

Figure 7.1.1 shows the interrupt processing sequence.

When an interrupt request is accepted, a branch is made to the start address of the interrupt routine set in the interrupt vector table (addresses FFCE₁₆ to FFFF₁₆). Set the start address of each interrupt routine to the corresponding interrupt vector address in the interrupt vector table.

Fig. 7.1.1 Interrupt processing sequence

When an interrupt request is accepted, the following registers' contents just before acceptance of an interrupt request are automatically pushed onto the stack area ①→②→③ in that order.

- ① Program bank register (PG)
- ② Program counter (PCL, PCH)
- ③ Processor status register (PSL, PSH)

Figure 7.1.2 shows the state of the stack area just before entering the interrupt routine. Execute the **RTI** instruction at the end of this interrupt routine to return to the routine that the microcomputer was executing before the interrupt request was accepted. By executing the **RTI** instruction, the register contents pushed onto the stack area are pulled ③→②→① in that order. Then, the suspended processing is resumed from where it left off.

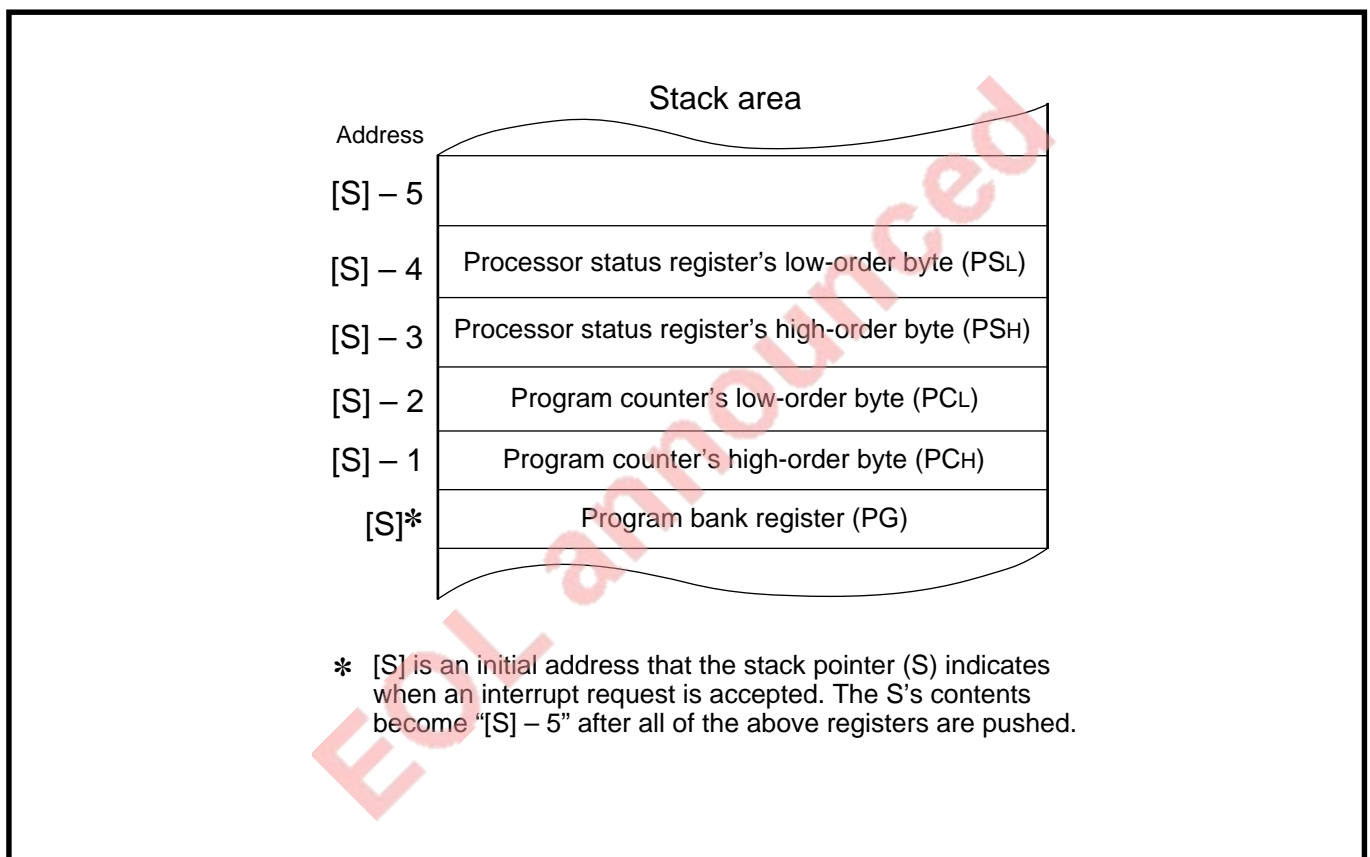

Fig. 7.1.2 State of stack area just before entering interrupt routine

INTERRUPTS

7.2 Interrupt sources

7.2 Interrupt sources

Table 7.2.1 lists the interrupt sources and the interrupt vector addresses. When programming, set the start address of each interrupt routine at the vector addresses listed in this table.

Table 7.2.1 Interrupt sources and interrupt vector addresses

Interrupt source	Interrupt vector addresses		Remarks	Reference
	High-order address	Low-order address		
Reset	FFFF ₁₆	FFFE ₁₆	Non-maskable	4. RESET

Note: The $\overline{\text{DBC}}$ interrupt is used exclusively for debugger control.

● **Maskable interrupt:** An interrupt of which request's acceptance can be disabled by software.

● **Non-maskable interrupt** (including Zero division, **BRK** instruction, Watchdog timer interrupts):

An interrupt which is certain to be accepted when its request occurs. These interrupts do not have their interrupt control registers and are not affected by the interrupt disable flag (I).

7.3 Interrupt control

The maskable interrupts are controlled by the following :

- Interrupt request bit
 - Interrupt priority level select bits
 - Processor interrupt priority level (IPL)
 - Interrupt disable flag (I)
- } Assigned to the interrupt control register of each interrupt.
- } Assigned to the processor status register (PS).

Figure 7.3.1 shows the memory assignment of the interrupt control registers, and Figure 7.3.2 shows their structures.

Address	
6C ₁₆	DMA0 interrupt control register
6D ₁₆	DMA1 interrupt control register
6E ₁₆	DMA2 interrupt control register

7F ₁₆	$\overline{\text{INT}}_2$ interrupt control register

Fig. 7.3.1 Memory assignment of interrupt control registers

INTERRUPTS

7.3 Interrupt control

Fig. 7.3.2 Structures of interrupt control register

7.3.1 Interrupt disable flag (I)

All maskable interrupts can be disabled by this flag. When this flag is set to “1,” all maskable interrupts are disabled; when this flag is cleared to “0,” those interrupts are enabled. Because this flag is set to “1” at reset, clear this flag to “0” when enabling interrupts.

7.3.2 Interrupt request bit

When an interrupt request occurs, this bit is set to “1.” This bit remains set to “1” until the interrupt request is accepted; it is cleared to “0” when the interrupt request is accepted.

This bit can also be set to “0” or “1” by software.

The $\overline{\text{INT}}_i$ interrupt request bit ($i = 0$ to 2) is ignored when the $\overline{\text{INT}}_i$ interrupt is used with level sense.

7.3.3 Interrupt priority level select bits and processor interrupt priority level (IPL)

The interrupt priority level select bits are used to determine the priority level of each interrupt.

When an interrupt request occurs, its interrupt priority level is compared with the processor interrupt priority level (IPL). The requested interrupt is enabled only when the comparison result meets the following condition.

Accordingly, an interrupt can be disabled by setting its interrupt priority level to 0.

Each interrupt priority level > Processor interrupt priority level (IPL)

Table 7.3.1 lists the setting of interrupt priority level, and Table 7.3.2 lists the interrupt enabled level corresponding to IPL contents.

The interrupt disable flag (I), interrupt request bit, interrupt priority level select bits, and processor interrupt priority level (IPL) are independent of one another; they do not affect one another. Interrupt requests are accepted only when the following conditions are satisfied.

- Interrupt disable flag (I) = “0”
- Interrupt request bit = “1”
- Interrupt priority level > Processor interrupt priority level (IPL)

INTERRUPTS

7.3 Interrupt control

Table 7.3.1 Setting of interrupt priority level

Interrupt priority level select bits			Interrupt priority level	Priority
b2	b1	b0		
0	0	0	Level 0 (Interrupt disabled)	—
0	0	1	Level 1	Low  High
0	1	0	Level 2	
0	1	1	Level 3	
1	0	0	Level 4	
1	0	1	Level 5	
1	1	0	Level 6	
1	1	1	Level 7	

Table 7.3.2 Interrupt enabled level corresponding to IPL contents

IPL ₂	IPL ₁	IPL ₀	Enabled interrupt priority level
0	0	0	Enable level 1 and above interrupts.
0	0	1	Enable level 2 and above interrupts.
0	1	0	Enable level 3 and above interrupts.
0	1	1	Enable level 4 and above interrupts.
1	0	0	Enable level 5 and above interrupts.
1	0	1	Enable level 6 and level 7 interrupts.
1	1	0	Enable only level 7 interrupt.
1	1	1	Disable all maskable interrupts.

IPL₀: Bit 8 in processor status register (PS)

IPL₁: Bit 9 in processor status register (PS)

IPL₂: Bit 10 in processor status register (PS)

7.4 Interrupt priority level

When the interrupt disable flag (I) = "0" (interrupts enabled) and more than one interrupt request is detected at the same sampling timing, which means a timing to check whether an interrupt request exists or not, they are accepted in order of priority levels. In other words, the interrupt request with the highest priority level is accepted first.

Among a total of 23 interrupt sources, the user can set the desired priority levels for 20 interrupt sources except software interrupts (zero division and **BRK** instruction interrupts) and the watchdog timer interrupt. Use the interrupt priority level select bits to set their priority levels. Priority levels of reset, which is handled as the interrupt request with the highest priority, and the watchdog timer interrupt are set by hardware. Figure 7.4.1 shows the interrupt priority set by hardware.

Note that software interrupts are not affected by the interrupt priority levels. Whenever the instruction is executed, a program certainly branches to the interrupt routine.

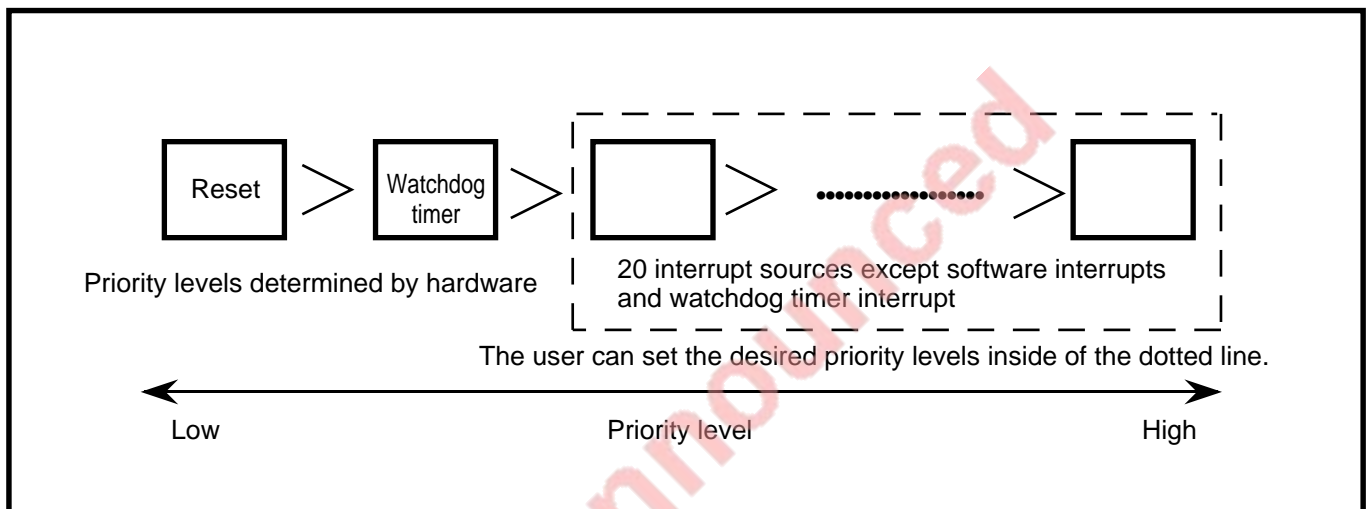

Fig. 7.4.1 Interrupt priority level set by hardware

INTERRUPTS

7.5 Interrupt priority level detection circuit

7.5 Interrupt priority level detection circuit

The interrupt priority level detection circuit selects the interrupt with the highest priority level when more than one interrupt request occurs at the same sampling timing. Figure 7.5.1 shows the interrupt priority level detection circuit.

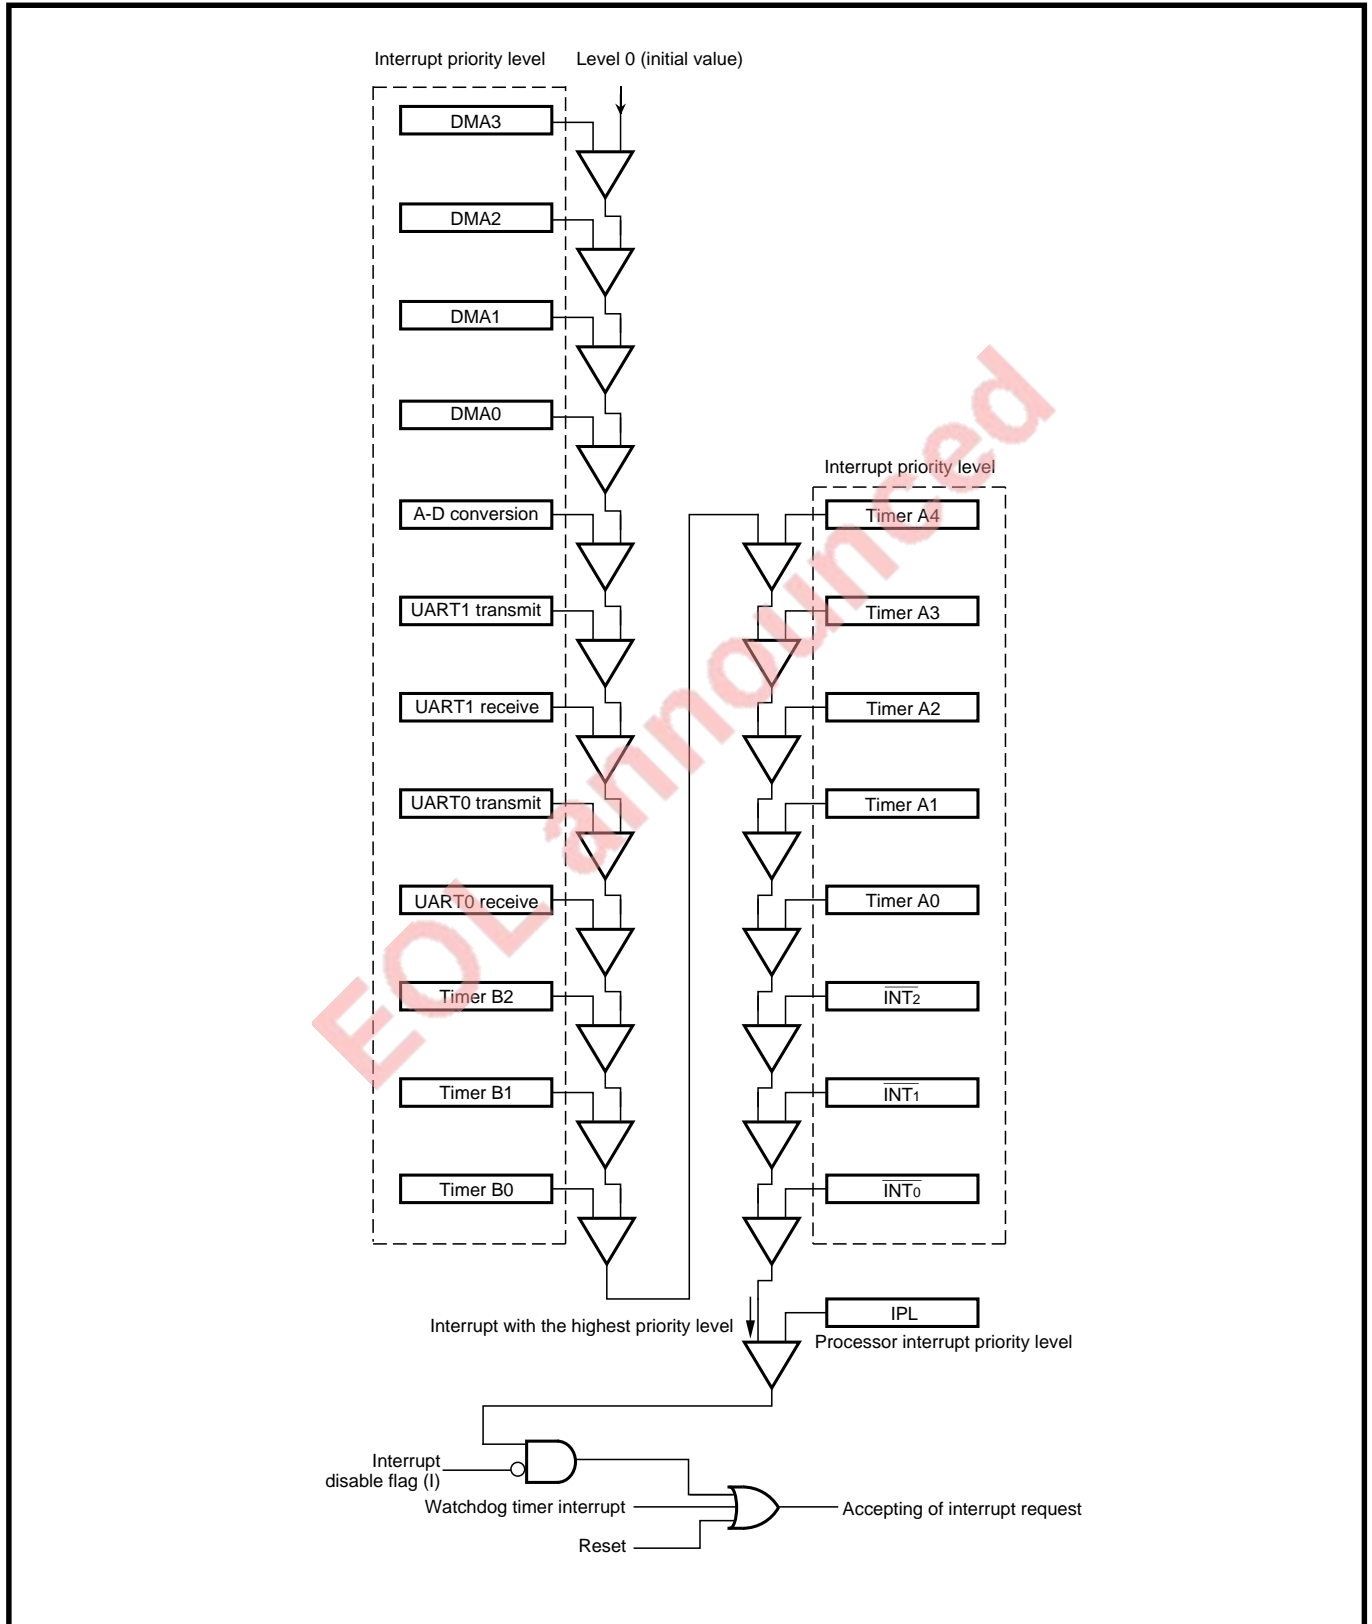

Fig. 7.5.1 Interrupt priority level detection circuit

INTERRUPTS

7.5 Interrupt priority level detection circuit

The following explains the operation of the interrupt priority detection circuit using Figure 7.5.2.

The interrupt priority level of a requested interrupt (Y in Figure 7.5.2) is compared with the resultant priority level which is sent from the preceding comparator (X in Figure 7.5.2); the interrupt with the higher priority level is sent to the next comparator (Z in Figure 7.5.2). (Initial comparison value of "X" is "0.") For an interrupt which is not requested, the comparison is not performed and the priority level which is sent from the preceding comparator is forwarded to the next comparator as it is. When the two priority levels are found the same by comparison, the priority level which is sent from the preceding comparator is forwarded to the next comparator. Accordingly, when the same priority level is set by software, the interrupt priority levels are handled as follows:

DMA3 > DMA2 > DMA1 > DMA0 > A-D conversion > UART1 transmit > UART1 receive > UART0 transmit > UART0 receive > Timer B2 > Timer B1 > Timer B0 > Timer A4 > Timer A3 > Timer A2 > Timer A1 > Timer A0 > INT₂ > INT₁ > INT₀

Among the multiple interrupt requests sampled at the same time, one request with the highest priority level is detected by the above comparison.

Then, this highest interrupt priority level is compared with the processor interrupt priority level (IPL). When this interrupt priority level is higher than the processor interrupt priority level (IPL) and the interrupt disable flag (I) is "0," the interrupt request is accepted. A interrupt request which is not accepted here is held until it is accepted or its interrupt request bit is cleared to "0" by software.

The interrupt priority is detected when the CPU fetches an op code, which is called the CPU's op-code fetch cycle. However, when an op-code fetch cycle starts during detection of an interrupt priority, a new interrupt priority detection does not start. (Refer to "Figure 7.6.1.") Since the state of the interrupt request bit and interrupt priority levels are latched during the interrupt priority detection, even if they change, the interrupt priority detection is performed for the previous state before the change occurred.

The interrupt priority level is detected when the CPU fetches an op code. Therefore, in the following execution or states, after the execution or state is terminated, no interrupt request is accepted until the CPU fetches the op code of the next instruction.

- Execution of an instruction which requires many cycles, such as the **MVN** or **MVP** instruction
- During DRAM refreshment
- During Hold state
- During DMA transfer

Fig. 7.5.2 Interrupt priority level detection model

INTERRUPTS

7.6 Interrupt priority level detection time

7.6 Interrupt priority level detection time

When the interrupt priority level detection time has passed after sampling starts, an interrupt request is accepted. The interrupt priority level detection time can be selected by software. Figure 7.6.1 shows the interrupt priority level detection time. Usually, select “2 cycles of ϕ ” as the interrupt priority level detection time.

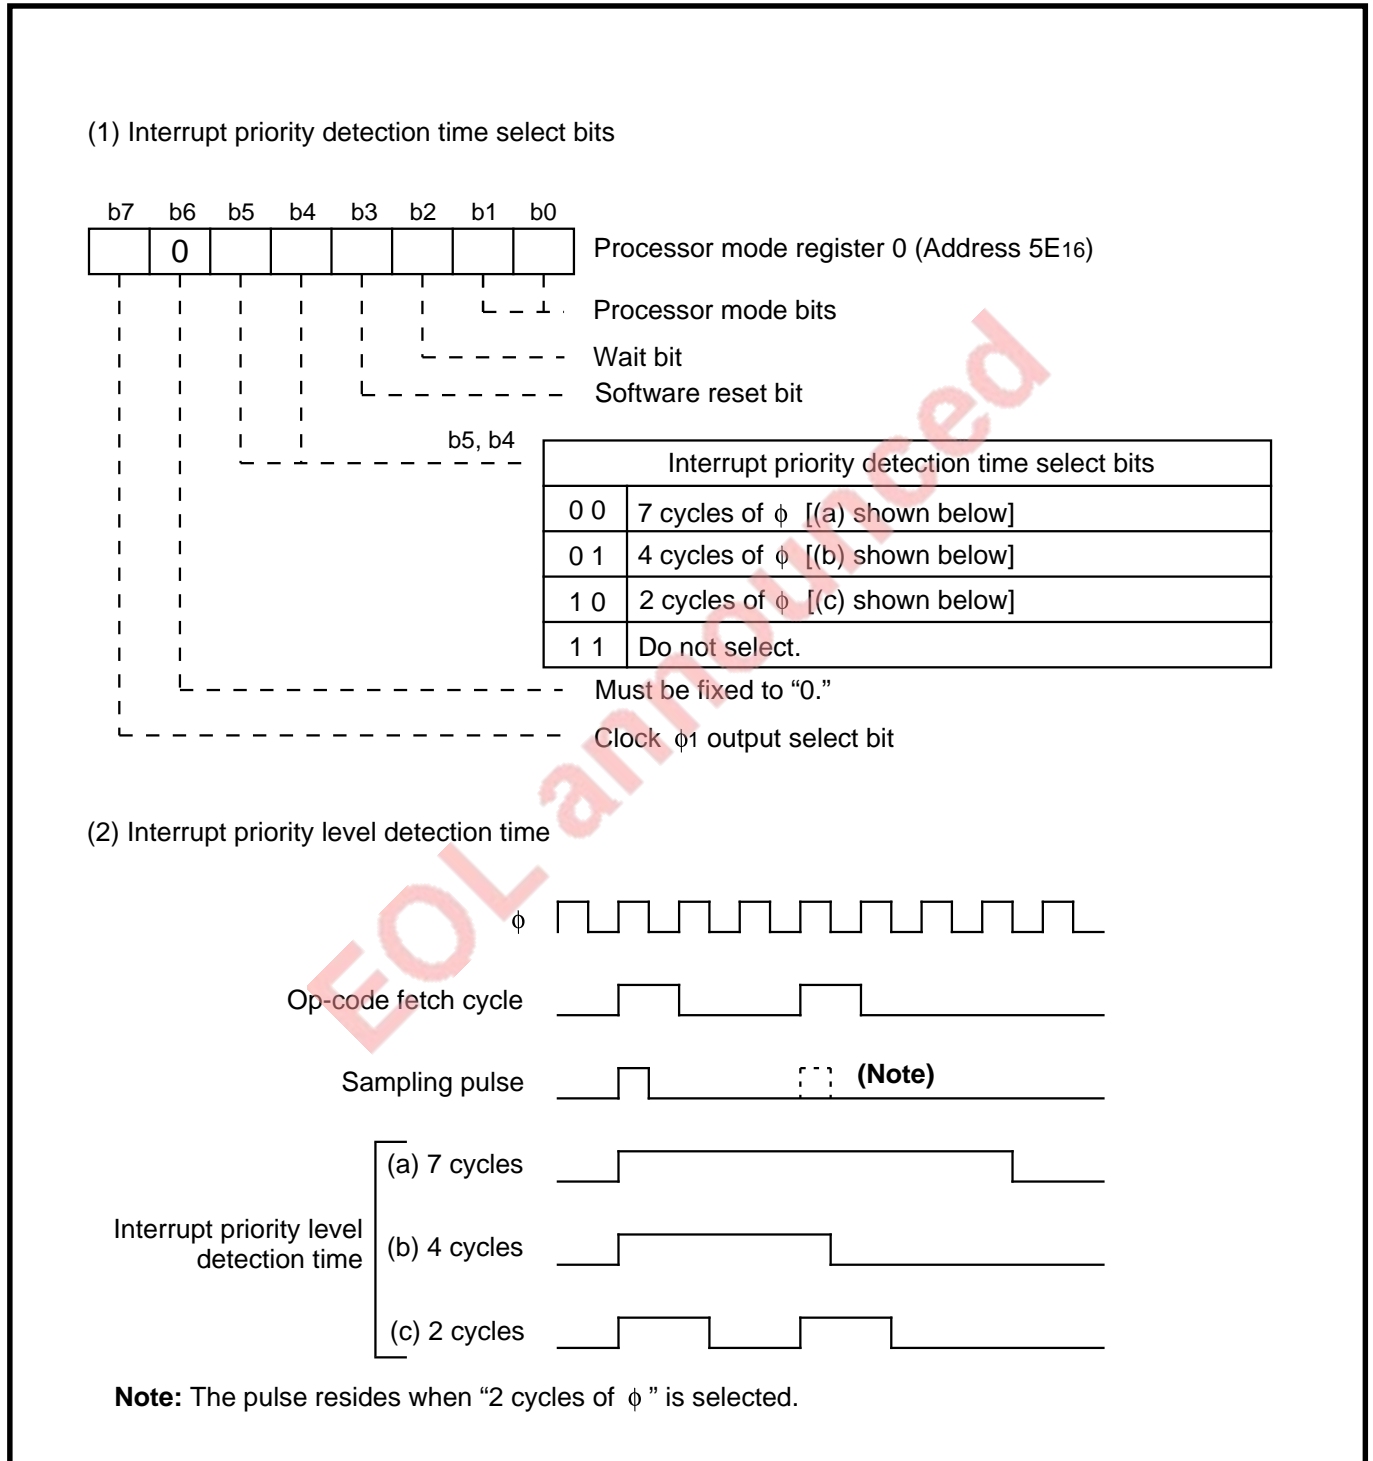

Fig. 7.6.1 Interrupt priority level detection time

7.7 Sequence from acceptance of interrupt request until execution of interrupt routine

7.7 Sequence from acceptance of interrupt request until execution of interrupt routine

The sequence from the acceptance of interrupt request until the execution of the interrupt routine is described below.

When an interrupt request is accepted, the interrupt request bit of the accepted interrupt is cleared to “0.” And then, the interrupt processing starts from the cycle just after the completion of the instruction which was executed at accepting the interrupt request. Figure 7.7.1 shows the sequence from acceptance of interrupt request to execution of interrupt routine. After execution of an instruction at accepting the interrupt request is completed, an INTACK (Interrupt Acknowledge) sequence is executed, and a branch is made to the start address of the interrupt routine allocated in addresses 0_{16} to $FFFF_{16}$.

The INTACK sequence is automatically performed in the following order.

- ① The contents of the program bank register (PG) just before performing the INTACK sequence are pushed onto stack.
- ② The contents of the program counter (PC) just before performing the INTACK sequence are pushed onto stack.
- ③ The contents of the processor status register (PS) just before performing the INTACK sequence is pushed onto stack.
- ④ The interrupt disable flag (I) is set to “1.”
- ⑤ The interrupt priority level of the accepted interrupt is set into the processor interrupt priority level (IPL).
- ⑥ The contents of the program bank register (PG) are cleared to “ 00_{16} ,” and the contents of the interrupt vector address are set into the program counter (PC).

Performing the INTACK sequence requires at least 13 cycles of internal clock ϕ . Figure 7.7.2 shows the INTACK sequence timing. After the INTACK sequence is completed, the instruction execution starts from the start address of the interrupt routine.

Fig. 7.7.1 Sequence from acceptance of interrupt request until execution of interrupt routine

INTERRUPTS

7.7 Sequence from acceptance of interrupt request until execution of interrupt routine

Fig. 7.7.2 INTACK sequence timing (at minimum)

7.7.1 Change in IPL at acceptance of interrupt request

When an interrupt request is accepted, the processor interrupt priority level (IPL) is replaced with the interrupt priority level of the accepted interrupt. This results in easy control of the processing for multiple interrupts. (Refer to section “7.9 Multiple interrupts.”)

At reset or when a watchdog timer interrupt or a software interrupt is accepted, a value listed in Table 7.7.1 is set into the IPL.

Table 7.7.1 Change in IPL at acceptance of interrupt request

Interrupts	Change in IPL
Reset	Level 0 (“000 ₂ ”) is set.
Watchdog timer	Level 7 (“111 ₂ ”) is set.
Zero division	Not changed.
BRK instruction	Not changed.
Other interrupts	Accepted interrupt priority level is set.

7.7 Sequence from acceptance of interrupt request until execution of interrupt routine

7.7.2 Push operation for registers

The push operation for registers performed in the INTACK sequence depends on whether the contents of the stack pointer (S) at acceptance of an interrupt request are even or odd.

When the contents of the stack pointer (S) are even, the contents of the program counter (PC) and the processor status register (PS) are simultaneously pushed in a unit of 16 bits. When the contents of the stack pointer (S) are odd, each of these registers is pushed in a unit of 8 bits. Figure 7.7.3 shows the push operation for registers.

In the INTACK sequence, only the contents of the program bank register (PG), program counter (PC), and processor status register (PS) are pushed onto the stack area. The other necessary registers must be pushed by software at the start of the interrupt routine.

By using the **PSH** instruction, all CPU registers except the stack pointer (S) can be pushed.

Fig. 7.7.3 Push operation for registers

INTERRUPTS

7.8 Return from interrupt routine, 7.9 Multiple interrupts

7.8 Return from interrupt routine

When the **RTI** instruction is executed at the end of the interrupt routine, the contents of the program bank register (PG), program counter (PC), and processor status register (PS) which were pushed onto the stack area just before the INTACK sequence, are automatically pulled. After this, the control returns to the original routine. And then, the suspended processing, which was in progress before the acceptance of the interrupt request, is resumed.

Before the **RTI** instruction is executed, pull registers which were pushed by software in the interrupt routine, using the **PUL** instruction, etc.

7.9 Multiple interrupts

Just after a branch is made to an interrupt routine, the following occur:

- Interrupt disable flag (I) = "1" (Interrupts are disabled)
- Interrupt request bit of accepted interrupt = "0"
- Processor interrupt priority level (IPL) = Interrupt priority level of accepted interrupt

Accordingly, as long as the IPL remains unchanged, an interrupt request whose priority level is higher than that of the interrupt which is in progress can be accepted by clearing the interrupt disable flag (I) to "0" in an interrupt routine. In this way, multiple interrupts are processed.

Figure 7.9.1 shows the processing for multiple interrupts.

An interrupt request which has not been accepted because its priority level is lower is held. When the **RTI** instruction is executed, the interrupt priority level of the routine which was in progress at acceptance of an interrupt request is pulled into the IPL. Therefore, if the following relationship is satisfied when interrupt priority level detection is performed next, the held interrupt request is accepted.

Held interrupt request's priority level > Processor interrupt priority level (IPL)

INTERRUPTS

7.10 External interrupts ($\overline{\text{INT}}_i$ interrupt)

7.10 External interrupts ($\overline{\text{INT}}_i$ interrupt)

An external interrupt request occurs by an input signal to the $\overline{\text{INT}}_i$ ($i = 0$ to 2) pin. The occurrence factor of the interrupt request can be selected by the level sense/edge sense select bit and the polarity select bit (bits 5 and 4 at addresses $7D_{16}$ to $7F_{16}$) shown in Figure 7.10.1. Table 7.10.1 lists the occurrence factor of $\overline{\text{INT}}_i$ interrupt request.

When using $P10_0/\overline{\text{INT}}_0$ to $P10_2/\overline{\text{INT}}_2$ pins as input pins of external interrupts, set the corresponding bits at address 18_{16} (port P10 direction register) to "0." (Refer to "Figure 7.10.2.")

The signals input to the $\overline{\text{INT}}_i$ pin require "H"- or "L"- level width of 250 ns or more, independent of $f(X_{IN})$. Additionally, even when using the pins $P10_0/\overline{\text{INT}}_0$ to $P10_2/\overline{\text{INT}}_2$ as the input pins of external interrupts, the user can obtain the pin's state by reading bits 0 to 2 at address 16_{16} (port P10 register).

Note: When selecting an input signal's falling or "L" level as the occurrence factor of an interrupt request, make sure that the input signal is held "L" for 250 ns or more. When selecting an input signal's rising or "H" level as that, make sure that the input signal is held "H" for 250 ns or more.

Table 7.10.1 Occurrence factor of $\overline{\text{INT}}_i$ interrupt request

b5	b4	$\overline{\text{INT}}_i$ interrupt request occurrence factor
0	0	Interrupt request occurs at the falling edge of a signal input to pin $\overline{\text{INT}}_i$ (Edge sense).
0	1	Interrupt request occurs at the rising edge of a signal input to pin $\overline{\text{INT}}_i$ (Edge sense).
1	0	Interrupt request occurs when pin $\overline{\text{INT}}_i$ is at "H" level (Level sense).
1	1	Interrupt request occurs when pin $\overline{\text{INT}}_i$ is at "L" level (Level sense).

The $\overline{\text{INT}}_i$ interrupt request occurs by detecting the state of pin $\overline{\text{INT}}_i$ all the time. Therefore, when the user does not use the $\overline{\text{INT}}_i$ interrupt, set the $\overline{\text{INT}}_i$ interrupt's priority level to level 0.

INTERRUPTS

7.10 External interrupts (\overline{INT}_i interrupt)

Fig. 7.10.1 Structure of INT_i (i=0 to 2) interrupt control register

Fig. 7.10.2 Relationship between port P10 direction register and input pins of external interrupt

INTERRUPTS

7.10 External interrupts ($\overline{\text{INT}}_i$ interrupt)

7.10.1 Functions of $\overline{\text{INT}}_i$ interrupt request bit

(1) Functions when edge sense is selected

The interrupt request bit has the same functions as that of an internal interrupt. That is, when an interrupt request occurs, the interrupt request bit is set to “1” and retains this state until the interrupt request is accepted. When this bit is cleared to “0” by software, the interrupt request is cancelled; when this bit is set to “1” by software, the interrupt request can be generated.

(2) Functions when level sense is selected

The $\overline{\text{INT}}_i$ interrupt request bit is ignored.

Interrupt requests continuously occur while the level of the $\overline{\text{INT}}_i$ pin is the valid level*¹; when the $\overline{\text{INT}}_i$ pin's level changes from the valid level to the invalid level*² before the $\overline{\text{INT}}_i$ interrupt request is accepted, this interrupt request is not retained. (Refer to “**Figure 7.10.4.**”)

Valid level*¹: This means the level selected by the polarity select bit (bit 4 at addresses 7D₁₆ to 7F₁₆)

Invalid level*²: This means the reversed level of “valid level”

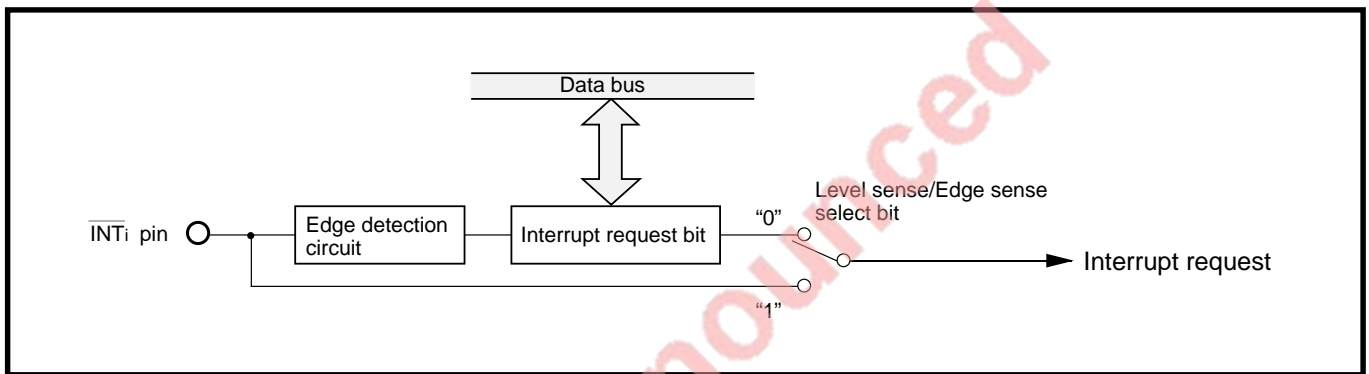

Fig. 7.10.3 $\overline{\text{INT}}_i$ Interrupt request

Fig. 7.10.4 Occurrence of $\overline{\text{INT}}_i$ interrupt request when level sense is selected

7.10 External interrupts (\overline{INT}_i interrupt)

7.10.2 Switching of \overline{INT}_i interrupt request occurrence factor

When the \overline{INT}_i interrupt request occurrence factor is switched in one of the following ways, the interrupt request bit may be set to "1":

- Switching the level sense to the edge sense
- Switching polarity

Therefore, after this switching, make sure to clear the interrupt request bit to "0." Figure 7.10.5 shows an example of the switching procedure for the \overline{INT}_i interrupt request occurrence factor.

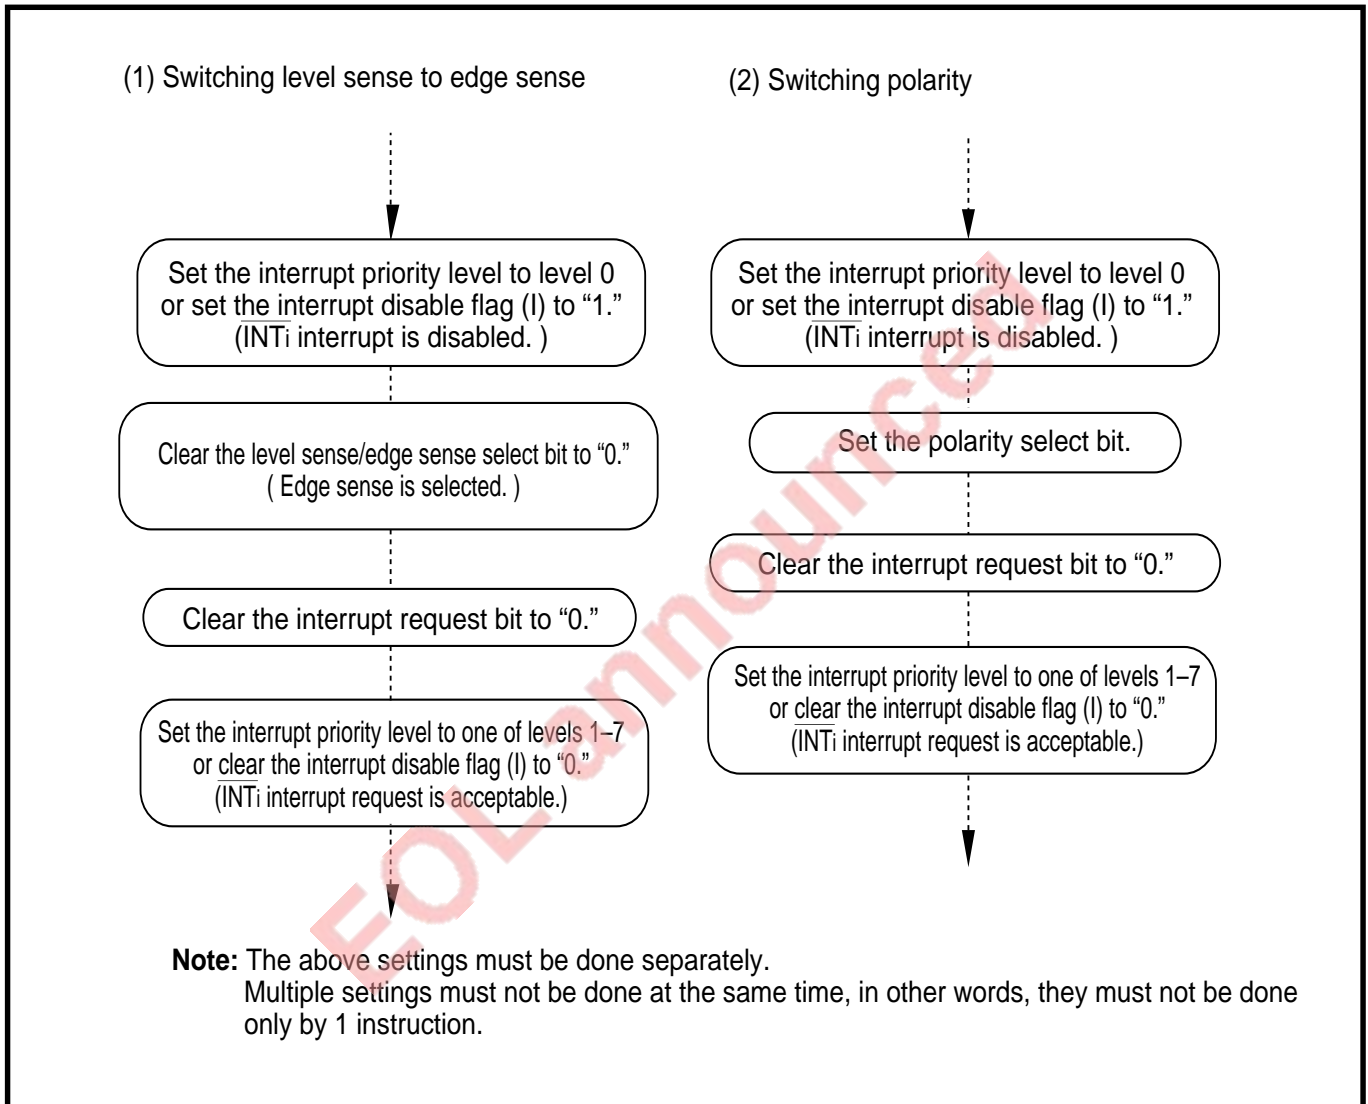

Fig. 7.10.5 Example of switching procedure for \overline{INT}_i interrupt request occurrence factor

INTERRUPTS

7.11 Precautions for interrupts

7.11 Precautions for interrupts

When changing the interrupt priority level select bits (bits 0 to 2 at addresses 6C₁₆ to 7F₁₆), 2 to 7 cycles of ϕ are required until the interrupt priority level is changed. Therefore, when the interrupt priority level of a certain interrupt source is repeatedly changed in a very short time, which consists of a few instructions, it is necessary to reserve the time required for the change by software. Figure 7.11.1 shows a program example to reserve the time required for the change. Note that the time required for the change depends on the contents of the interrupt priority detection time select bits (bits 4 and 5 at address 5E₁₆). Table 7.11.1 lists the correspondence between the number of instructions inserted in Figure 7.11.1 and the interrupt priority detection time select bits.

```

:
LDM.B #0XH, 00XXH ; Write instruction for the interrupt priority level select bits
NOP                ; Inserted NOP instruction (Note)
NOP                ;
NOP                ;
NOP                ;
LDM.B #0XH, 00XXH ; Write instruction for the interrupt priority level select bits
:

```

Note: Except the write instruction for address XX₁₆, any instruction which has the same cycles as the **NOP** instruction can also be inserted.
For the number of inserted **NOP** instructions, refer to “Table 7.11.1.”

XX: any of 6C to 7F

Fig. 7.11.1 Program example to reserve time required for change of interrupt priority level

Table 7.11.1 Correspondence between number of instructions to be inserted in Figure 7.11.1 and interrupt priority detection time select bits

Interrupt priority detection time select bits (Note)		Interrupt priority level detection time	Number of inserted NOP instructions
b5	b4		
0	0	7 cycles of ϕ	4 or more
0	1	4 cycles of ϕ	2 or more
1	0	2 cycles of ϕ	1 or more
1	1	Do not select.	

Note: We recommend [b5 = “1”, b4 = “0”].

TIMER A

8.1 Overview

8.1 Overview

Timer A consists of five counters, Timers A0 to A4, each equipped with a 16-bit reload function. Timers A0 to A4 operate independently of one another.

Timer A has four operating modes listed below. Timers A0 and A1 operate in the timer mode only. Timers A2 to A4 have selective four operating modes listed below.

(1) Timer mode (Timers A0 to A4)

The timer counts an internally generated count source. For Timers A2 to A4, the following functions can be used in this mode:

- Gate function
- Pulse output function

(2) Event counter mode (Timers A2 to A4)

The timer counts an external signal. The following functions can be used in this mode:

- Pulse output function
- Two-phase pulse signal processing function

(3) One-shot pulse mode (Timers A2 to A4)

The timer outputs a pulse which has an arbitrary width once.

(4) Pulse width modulation (PWM) mode (Timers A2 to A4)

Timer outputs pulses which have an arbitrary width in succession. The counter functions as one of the following pulse width modulators:

- 16-bit pulse width modulator
- 8-bit pulse width modulator

In this chapter, Timer A_i (i = 0 to 4) indicates Timers A0 to A4. Timer A_j (j = 2 to 4) indicates Timers A2 to A4; this is applies when the timer A's input/output pins are used etc. (Hereafter, input/output pins are called I/O pins.)

8.2 Block description

Figure 8.2.1 shows the block diagram of Timer A. Explanation of registers relevant to Timer A is described below.

Fig. 8.2.1 Block diagram of Timer A

TIMER A

8.2 Block description

8.2.1 Counter and reload register (timer Ai register)

Each of timer Ai counter and reload register consists of 16 bits.

Countdown in the counter is performed each time the count source is input. In the event counter mode, it can also function as an up-counter.

The reload register is used to store the initial value of the counter. When a counter underflow or overflow occurs, the reload register's contents are reloaded into the counter.

A value is set to the counter and reload register by writing the value to the timer Ai register. Table 8.2.1 lists the memory assignment of the timer Ai register.

The value written into the timer Ai register while counting is not in progress is set to the counter and reload register. The value written into the timer Ai register while counting is in progress is set only to the reload register. In this case, the reload register's updated contents are transferred to the counter at the next reload time. The value obtained when reading out the timer Ai register varies according to the operating mode. Table 8.2.2 lists reading from and writing to the timer Ai register.

Table 8.2.1 Memory assignment of timer Ai register

Timer Ai register	High-order byte	Low-order byte
Timer A0 register	Address 47 ₁₆	Address 46 ₁₆
Timer A1 register	Address 49 ₁₆	Address 48 ₁₆
Timer A2 register	Address 4B ₁₆	Address 4A ₁₆
Timer A3 register	Address 4D ₁₆	Address 4C ₁₆
Timer A4 register	Address 4F ₁₆	Address 4E ₁₆

Note: At reset, the contents of the timer Ai register are undefined.

Table 8.2.2 Reading from and writing to timer Ai register

Operating mode	Read	Write
Timer mode	Counter value is read out. (Note 1)	<While counting> Written only to reload register.
Event counter mode		<While not counting> Written to both of the counter and reload register.
One-shot pulse mode	Undefined value is read out.	
Pulse width modulation (PWM) mode		

Notes 1: Also refer to “[Precautions for timer mode]” and “[Precautions for event counter mode].”

2: When reading from and writing to the timer Ai register, perform it in a unit of 16 bits.

8.2.2 Count start register

This register is used to start and stop counting. Each bit of this register corresponds to each timer. Figure 8.2.2 shows the structure of the count start register.

Fig. 8.2.2 Structure of count start register

TIMER A

8.2 Block description

8.2.3 Timer Ai mode register

Figure 8.2.3 shows the structure of the timer Ai mode register. The operating mode select bits are used to select the operating mode of Timer Ai. Bits 2 to 7 have different functions according to the operating mode. These bits are described in the paragraph of each operating mode.

Fig. 8.2.3 Structure of timer Ai mode register

8.2.4 Timer Ai interrupt control register

Figure 8.2.4 shows the structure of the timer Ai interrupt control register. For details about interrupts, refer to “CHAPTER 7. INTERRUPTS.”

Fig. 8.2.4 Structure of timer Ai interrupt control register

(1) Interrupt priority level select bits (bits 2 to 0)

These bits select a timer Ai interrupt’s priority level. When using timer Ai interrupts, select one of the priority levels (1 to 7). When a timer Ai interrupt request occurs, its priority level is compared with the processor interrupt priority level (IPL). The requested interrupt is enabled only when its priority level is higher than the IPL. (However, this applies when the interrupt disable flag (I) = “0.”) To disable timer Ai interrupts, set these bits to “000₂” (level 0).

(2) Interrupt request bit (bit 3)

This bit is set to “1” when a timer Ai interrupt request occurs. This bit is automatically cleared to “0” when the timer Ai interrupt request is accepted. This bit can be set to “1” or cleared to “0” by software.

TIMER A

8.2 Block description

8.2.5 Port P5 direction register

The I/O pins of Timers A2 to A4 are multiplexed with port P5. When using these pins as Timer Aj's input pins, set the corresponding bits of the port P5 direction register to "0" to set these port pins for the input mode. When used as Timer Aj's output pins, these pins are forcibly set to the output pins of Timer Aj regardless of the direction registers's contents. Figure 8.2.5 shows the relationship between the port P5 direction register and the Timer Aj's I/O pins.

Fig. 8.2.5 Relationship between port P5 direction register and Timer Aj's I/O pins

8.3 Timer mode

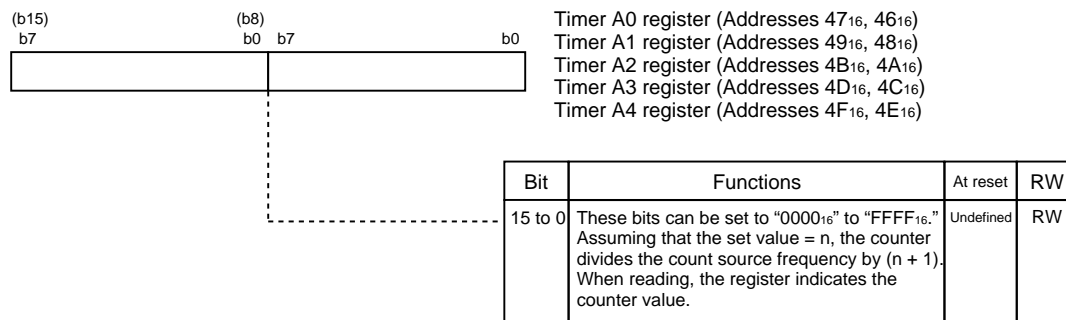

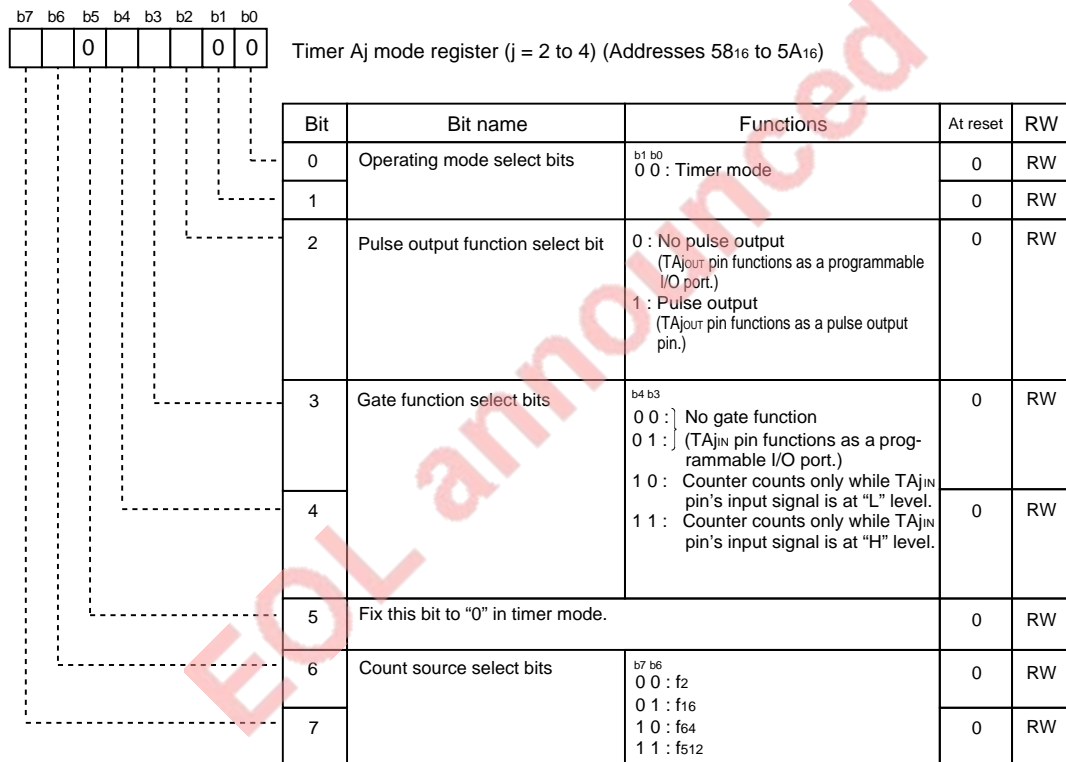

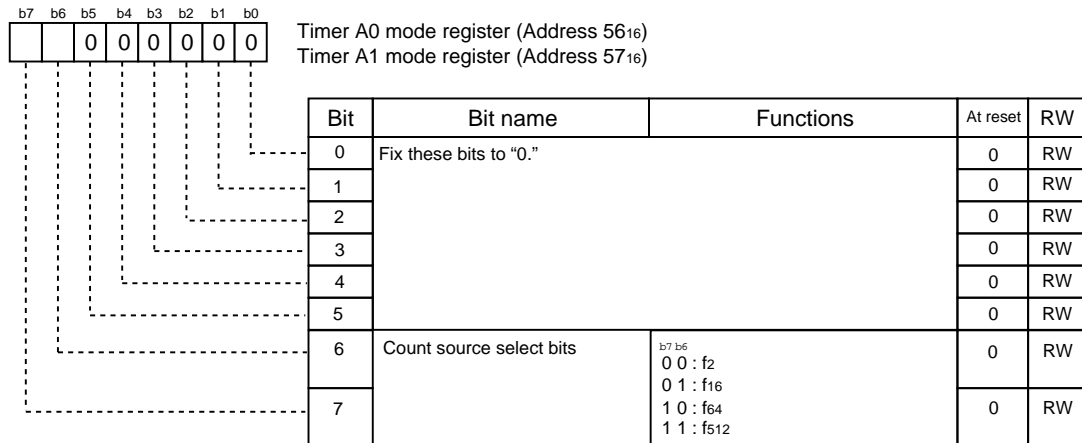

In this mode, the timer counts an internally generated count source. (Refer to “Table 8.3.1.”) Figure 8.3.1 shows the structures of the timer Ai mode register and timer Ai register in the timer mode.

Table 8.3.1 Specifications of timer mode

Item	Specifications
Count source	f_2 , f_{16} , f_{64} , or f_{512}
Count operation	<ul style="list-style-type: none"> Countdown When a counter underflow occurs, reload register's contents are reloaded, and counting continues.
Division ratio	$\frac{1}{(n + 1)}$ n : Timer Ai register's set value
Count start condition	When the count start bit is set to “1.”
Count stop condition	When the count start bit is cleared to “0.”
Interrupt request occurrence timing	When a counter underflow occurs.
TA _{JIN} pin's function	Programmable I/O port or gate input
TA _{JOUT} pin's function	Programmable I/O port or pulse output
Read from timer Ai register	Counter value can be read out.
Write to timer Ai register	<ul style="list-style-type: none"> While counting is stopped When a value is written to the timer Ai register, it is written to both of the reload register and counter. While counting is in progress When a value is written to the timer Ai register, it is written only to the reload register. (Transferred to the counter at the next reload timing.)

TIMER A

8.3 Timer mode

Note: Read from or write to this register in a unit of 16 bits.

Fig. 8.3.1 Structures of timer A_i mode register and timer A_i register in timer mode

8.3.1 Setting for timer mode

Figures 8.3.2 and 8.3.3 show an initial setting example for registers relevant to the timer mode.

Note that when using interrupts, set up to enable the interrupts. For details, refer to section “CHAPTER 7. INTERRUPTS.”

Fig. 8.3.2 Initial setting example for registers relevant to timer mode (1)

TIMER A

8.3 Timer mode

Fig. 8.3.3 Initial setting example for registers relevant to timer mode (2)

8.3.2 Count source

In the timer mode, the count source select bits (bits 6 and 7 at addresses 56₁₆ to 5A₁₆) select the count source. Table 8.3.2 lists the count source frequency.

Table 8.3.2 Count source frequency

Count source select bits		Count source	Count source frequency		
b7	b6		f(X _{IN}) = 8 MHz	f(X _{IN}) = 16 MHz	f(X _{IN}) = 25 MHz
0	0	f ₂	4 MHz	8 MHz	12.5 MHz
0	1	f ₁₆	500 kHz	1 MHz	1.5625 MHz
1	0	f ₆₄	125 kHz	250 kHz	390.625 kHz
1	1	f ₅₁₂	15625 Hz	31250 Hz	48.8281 kHz

EOL announced

TIMER A

8.3 Timer mode

8.3.3 Operation in timer mode

- ① When the count start bit is set to "1," the counter starts counting of the count source.
- ② When a counter underflow occurs, the reload register's contents are reloaded, and counting continues.
- ③ The timer Ai interrupt request bit is set to "1" at the underflow in ②. The interrupt request bit remains set to "1" until the interrupt request is accepted or the interrupt request bit is cleared to "0" by software.

Figure 8.3.4 shows an example of operation in the timer mode.

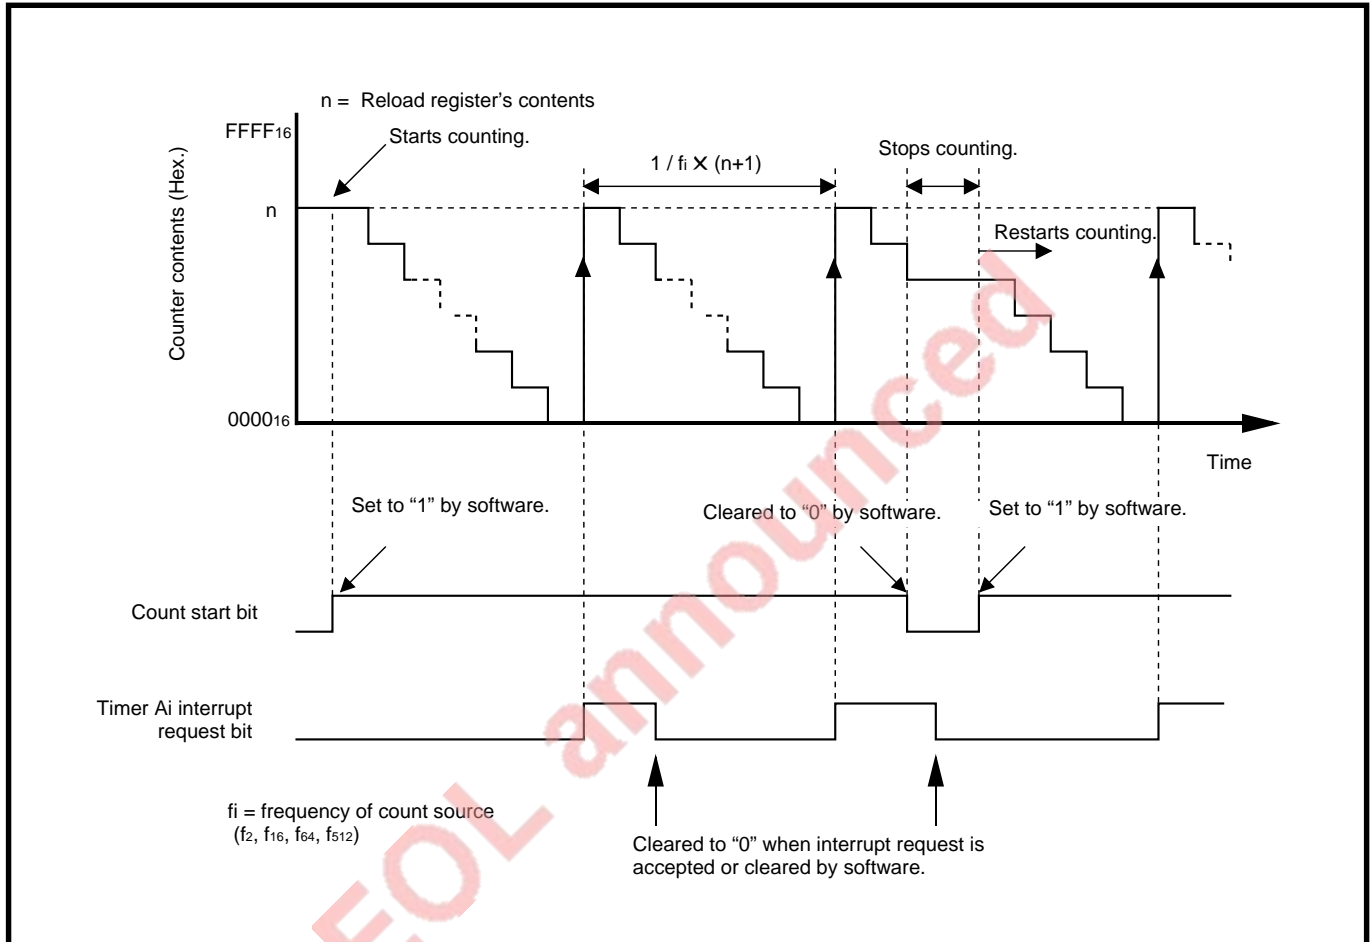

Fig. 8.3.4 Example of operation in timer mode (without pulse output and gate functions)

8.3.4 Selectable functions

The following describes the selectable gate function for Timers A2 to A4 and pulse output function.

(1) Gate function

The gate function is selected by setting the gate function select bits (bits 4 and 3 at addresses 58_{16} to $5A_{16}$) to "10₂" or "11₂." The gate function makes it possible to start or stop counting depending on the TA_{jIN} pin's input signal. Table 8.3.3 lists the count valid levels. Figure 8.3.5 shows an example of operation with the gate function selected.

When selecting the gate function, set the port P5 direction registers' bits which correspond to the TA_{jIN} pin for the input mode. Additionally, make sure that the TA_{jIN} pin's input signal has a pulse width equal to or more than two cycles of the count source.

Table 8.3.3 Count valid levels

Gate function select bits		Count valid level (Duration while counter counts)
b4	b3	
1	0	While TA_{jIN} pin's input signal is at "L" level
1	1	While TA_{jIN} pin's input signal is at "H" level

Note: The counter does not count while the TA_{jIN} pin's input signal is not at the count valid level.

Fig. 8.3.5 Example of operation selecting gate function

TIMER A

8.3 Timer mode

(2) Pulse output function

The pulse output function is selected by setting the pulse output function select bit (bit 2 at addresses 58₁₆ to 5A₁₆) to "1." When this function is selected, the TAJ_{OUT} pin is forcibly set for the pulse output pin regardless of the corresponding bits of the port P5 direction register. The TAJ_{OUT} pin outputs pulses of which polarity is inverted each time a counter underflow occurs.

When the count start bit (address 40₁₆) is "0" (count stopped), the TAJ_{OUT} pin outputs "L" level. Figure 8.3.6 shows an example of operation with the pulse output function selected.

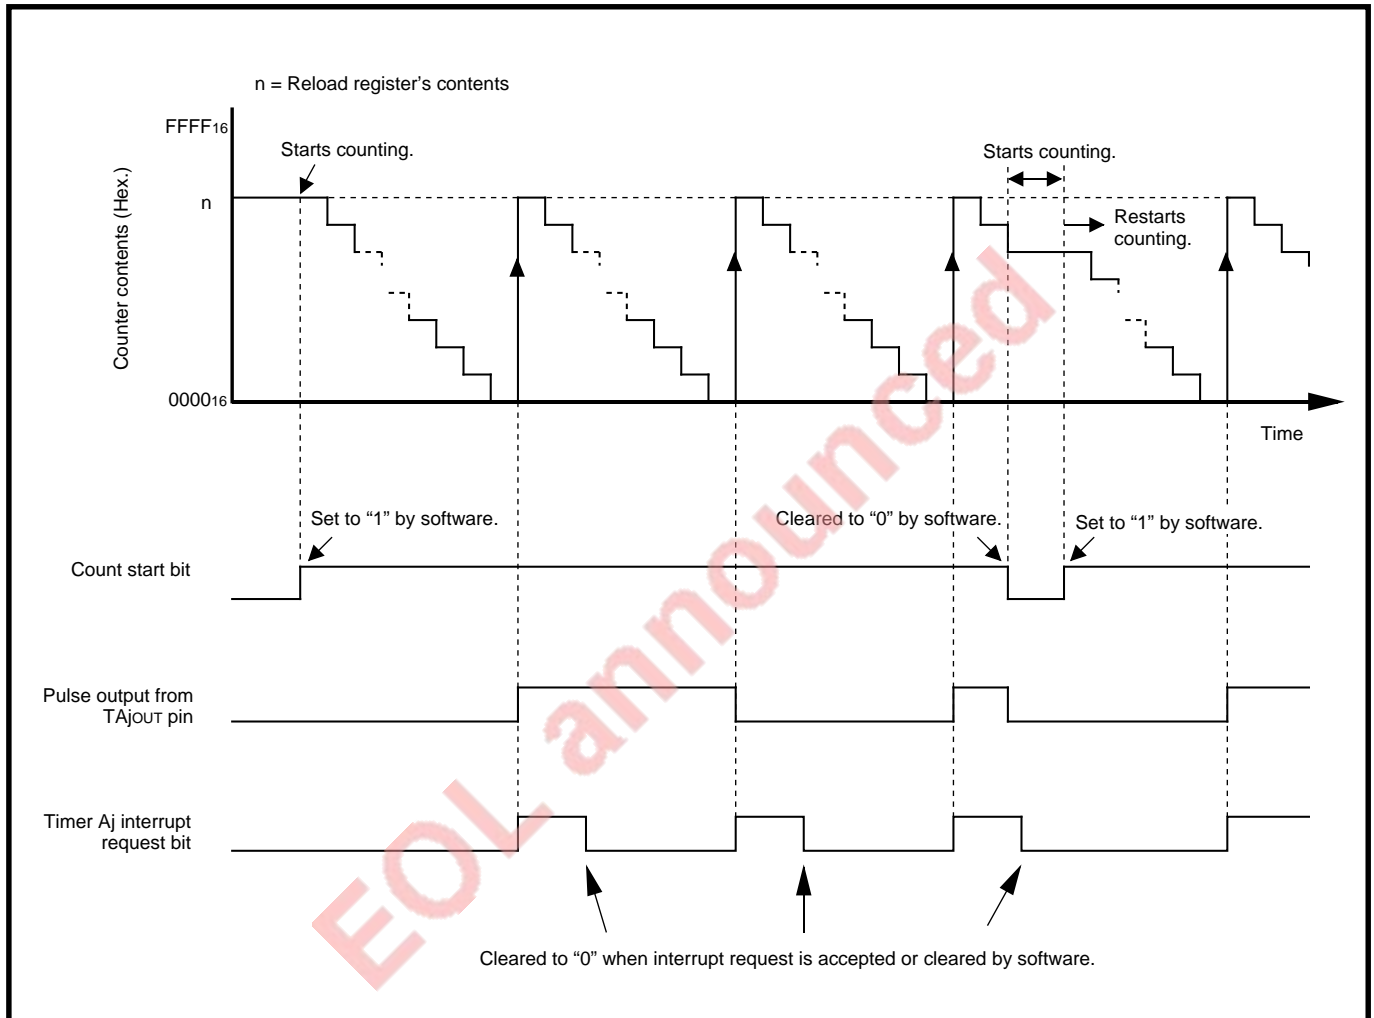

Fig. 8.3.6 Example of operation selecting pulse output function

[Precautions for timer mode]

By reading the timer Ai register, the counter value can be read out at any timing. However, if the timer Ai register is read at the reload timing shown in Figure 8.3.7, the value “FFFF₁₆” is read out. If reading is performed in the period from when a value is set into the timer Ai register with the counter stopped until the counter starts counting, the set value is correctly read out.

Fig. 8.3.7 Reading timer Ai register

TIMER A

8.4 Event counter mode

8.4 Event counter mode

In this mode, the timer counts an external signal. (Refer to “Tables 8.4.1 and 8.4.2.”) Timers A2 to A4 can be used in this mode. Figure 8.4.1 shows the structures of the timer Aj mode register and timer Aj register in the event counter mode.

Table 8.4.1 Specifications of event counter mode (when not using two-phase pulse signal processing function)

Item	Specifications
Count source	<ul style="list-style-type: none"> ● External signal input to the TAJ_{IN} pin ● The count source's valid edge can be selected from the falling edge and the rising edge by software.

Fig. 8.4.4 Example of operation in event counter mode (without pulse output and two-phase pulse signal processing functions)

TIMER A

8.4 Event counter mode

8.4.3 Switching between countup and countdown

The up-down register (address 44₁₆) or the input signal from the TAJ_{OUT} pin is used to switch countup from and to countdown. This switching is performed by the up-down bit when the up-down switching factor select bit (bit 4 at addresses 58₁₆ to 5A₁₆) is “0,” and by the input signal from the TAJ_{OUT} pin when the up-down switching factor select bit is “1.”

When the switching between countup and countdown is set while counting is in progress, this switching is actually performed when the count source’s next valid edge is input.

(1) Switching by up-down bit

Countdown is performed when the up-down bit is “0,” and countup is performed when the up-down bit is “1.” Figure 8.4.5 shows the structure of the up-down register.

(2) Switching by TAJ_{OUT} pin’s input signal

Countdown is performed when the TAJ_{OUT} pin’s input signal is at “L” level, and countup is performed when the TAJ_{OUT} pin’s input signal is at “H” level.

When using the TAJ_{OUT} pin’s input signal to switch countup from and to countdown, set the port P5 direction register’s bit which corresponds to the TAJ_{OUT} pin for the input mode.

Fig. 8.4.5 Structure of up-down register

8.4.4 Selectable functions

The following describes the selectable pulse output, and two-phase pulse signal processing functions.

(1) Pulse output function

The pulse output function is selected by setting the pulse output function select bit (bit 2 at addresses 58₁₆ to 5A₁₆) to "1." When this function is selected, the TA_{JOUT} pin is forcibly set for the pulse output pin regardless of the corresponding bit of the port P5 direction register. The TA_{JOUT} pin outputs pulses of which polarity is inverted each time a counter underflow or overflow occurs. (Refer to "Figure 8.3.6.")

When the count start bit (address 40₁₆) is "0" (count stopped), the TA_{JOUT} pin outputs "L" level.

EOL announced

TIMER A

8.4 Event counter mode

(2) Two-phase pulse signal processing function

The two-phase pulse signal processing function is selected by setting the two-phase pulse signal processing select bits (bits 5 to 7 at address 44₁₆) to “1.” (Refer to “**Figure 8.4.5.**”) Figure 8.4.6 shows the timer A_j mode registers when the two-phase pulse signal processing function is selected. For timers with the two-phase pulse signal processing function selected, the timer counts two kinds of pulses of which phases differ by 90 degrees. There are two types of the two-phase pulse signal processing: normal processing and quadruple processing. In Timers A2 and A3, normal processing is performed; in timer A4, quadruple processing is performed.

For some bits of the port P5 direction register correspond to pins used for two-phase pulse input, set these bits for the input mode.

Fig. 8.4.6 Timer A_j mode registers when two-phase pulse signal processing function is selected

●Normal processing

Countup is performed at the rising edges input to the TAK_{IN} pin when the phase has the relationship that the TAK_{IN} pin’s input signal level goes from “L” to “H” while the TAK_{OUT} (k = 2 and 3) pin’s input signal is at “H” level.

Countdown is performed at the falling edges input to the TAK_{IN} pin when the phase has the relationship that the TAK_{IN} pin’s input signal level goes from “H” to “L” while the TAK_{OUT} pin’s input signal is at “H” level. (Refer to “**Figure 8.4.7.**”)

Fig. 8.4.7 Normal processing

● Quadruple processing

Countup is performed at all rising and falling edges input to the TA4_{OUT} and TA4_{IN} pins when the phase has the relationship that the TA4_{IN} pin's input signal level goes from "L" to "H" while the TA4_{OUT} pin's input signal is at "H" level.

Countdown is performed at all rising and falling edges input to the TA4_{OUT} and TA4_{IN} pins when the phase has the relationship that the TA4_{IN} pin's input signal level goes from "H" to "L" while the TA4_{OUT} pin's input signal is at "H" level. (Refer to "Figure 8.4.8.")

Table 8.4.3 lists the relationship between the input signals to the TA4_{OUT} and TA4_{IN} pins and count operation when the quadruple processing is selected.

Fig. 8.4.8 Quadruple processing

Table 8.4.3 Relationship between input signals to TA4_{OUT} and TA4_{IN} pins and count operation when quadruple processing is selected

	Input signal to TA4 _{OUT} pin	Input signal to TA4 _{IN} pin
Up-count	"H" level	Rising edge
	"L" level	Falling edge
	Rising edge	"L" level
	Falling edge	"H" level
Down-count	"H" level	Falling edge
	"L" level	Rising edge
	Rising edge	"H" level
	Falling edge	"L" level

TIMER A

8.4 Event counter mode

[Precautions for event counter mode]

1. While counting is in progress, by reading the timer Aj register, the counter value can be read out at any timing. However, if the timer Aj register is read at the reload timing shown in Figure 8.4.9, the value “FFFF₁₆” (at an underflow) or “0000₁₆” (at an overflow) is read out. If reading is performed in the period from when a value is set into the timer Aj register with the counter stopped until the counter starts counting, the set value is correctly read out.

Fig. 8.4.9 Reading timer Aj register

2. The TAJ_{OUT} pin is used for all functions listed below. Accordingly, only one of these functions can be selected for each timer.
 - Switching between countup and countdown by TAJ_{OUT} pin's input signal
 - Pulse output function
 - Two-phase pulse signal processing function

8.5 One-shot pulse mode

In this mode, the timer outputs a pulse which has an arbitrary width once. (Refer to “Table 8.5.1.”) Timers A2 to A4 can be used in this mode. When a trigger occurs, the timer outputs “H” level from the TAJ_{OUT} pin for an arbitrary time. Figure 8.5.1 shows the structures of the timer Aj mode register and timer Aj register in the one-shot pulse mode.

Table 8.5.1 Specifications of one-shot pulse mode

Item	Specifications
Count source	f ₂ , f ₁₆ , f ₆₄ , or f ₅₁₂
Count operation	<ul style="list-style-type: none"> ● Countdown ● When the counter value becomes “0000₁₆,” reload register’s contents are reloaded, and counting stops. ● If a trigger occurs during counting, reload register’s contents are reloaded, and counting continues.
Output pulse width (“H”)	$\frac{n}{f_i}$ [S] n : Timer Aj register’s set value

EOL announced

TIMER A

8.5 One-shot pulse mode

8.5.3 Trigger

The counter is enabled for counting when the count start bit (address 40₁₆) is set to “1.” The counter starts counting when a trigger is generated after counting has been enabled. An internal or external trigger can be selected as that trigger.

An internal trigger is selected when the trigger select bits (bits 4 and 3 at addresses 58₁₆ to 5A₁₆) are “00₂” or “01₂”; an external trigger is selected when the bits are “10₂” or “11₂.”

If a trigger is generated during counting, the reload register’s contents are reloaded and the counter continues counting. If generating a trigger during counting, make sure that a certain time which is equivalent to one cycle of the timer’s count source or more has passed between the previously generated trigger and a new trigger.

(1) When selecting internal trigger

A trigger is generated when writing “1” to the one-shot start bit (bits 2 to 4 at address 42₁₆). Figure 8.5.4 shows the structure of the one-shot start register.

(2) When selecting external trigger

A trigger is generated at the falling edge of the TAJ_{IN} pin’s input signal when bit 3 at addresses 58₁₆ to 5A₁₆ is “0,” or at its rising edge when bit 3 is “1.”

When using an external trigger, set the port P5 direction registers’ bits which correspond to the TAJ_{IN} pins for the input mode.

Fig. 8.5.4 Structure of one-shot start register

8.5.4 Operation in one-shot pulse mode

- ① When the one-shot pulse mode is selected with the operating mode select bits, the TAJ_{OUT} pin outputs “L” level.
- ② When the count start bit is set to “1,” the counter is enabled for counting. After that, counting starts when a trigger is generated.
- ③ When the counter starts counting, the TAJ_{OUT} pin outputs “H” level.
- ④ When the counter value becomes “0000₁₆,” the output from the TAJ_{OUT} pin becomes “L” level. Additionally, the reload register’s contents are reloaded and the counter stops counting there.
- ⑤ Simultaneously with ④, the timer Aj interrupt request bit is set to “1.”
This interrupt request bit remains set to “1” until the interrupt request is accepted or the interrupt request bit is cleared to “0” by software.

Figure 8.5.5 shows an example of operation in the one-shot pulse mode.

When a trigger is generated after ④ above, the counter and TAJ_{OUT} pin perform the same operations beginning from ② again. Furthermore, if a trigger is generated during counting, the counter performs countdown once after this new trigger is generated, and it continues counting with the reload register’s contents reloaded. If generating a trigger during counting, make sure that a certain time which is equivalent to one cycle of the timer’s count source or more has passed between the previously generated trigger and a new trigger.

The one-shot pulse output from the TAJ_{OUT} pin can be disabled by clearing the timer Aj mode register’s bit 2 to “0.” Accordingly, Timer Aj can be also used as an internal one-shot timer that does not perform the pulse output. In this case, the TAJ_{OUT} pin functions as a programmable I/O port.

EOL announced

TIMER A

8.5 One-shot pulse mode

Fig. 8.5.5 Example of operation in one-shot pulse mode (selecting external trigger)

[Precautions for one-shot pulse mode]

- If the count start bit is cleared to "0" during counting, the counter becomes as follows:
 - The counter stops counting, and the reload register's contents are reloaded into the counter.
 - The TA_{JOUT} pin's output level becomes "L."
 - The timer Aj interrupt request bit is set to "1."
- A one-shot pulse is output synchronously with an internally generated count source. Accordingly, when selecting an external trigger, there will be a delay equivalent to one cycle of the count source at maximum from when a trigger is input to the TA_{JIN} pin until a one-shot pulse is output.

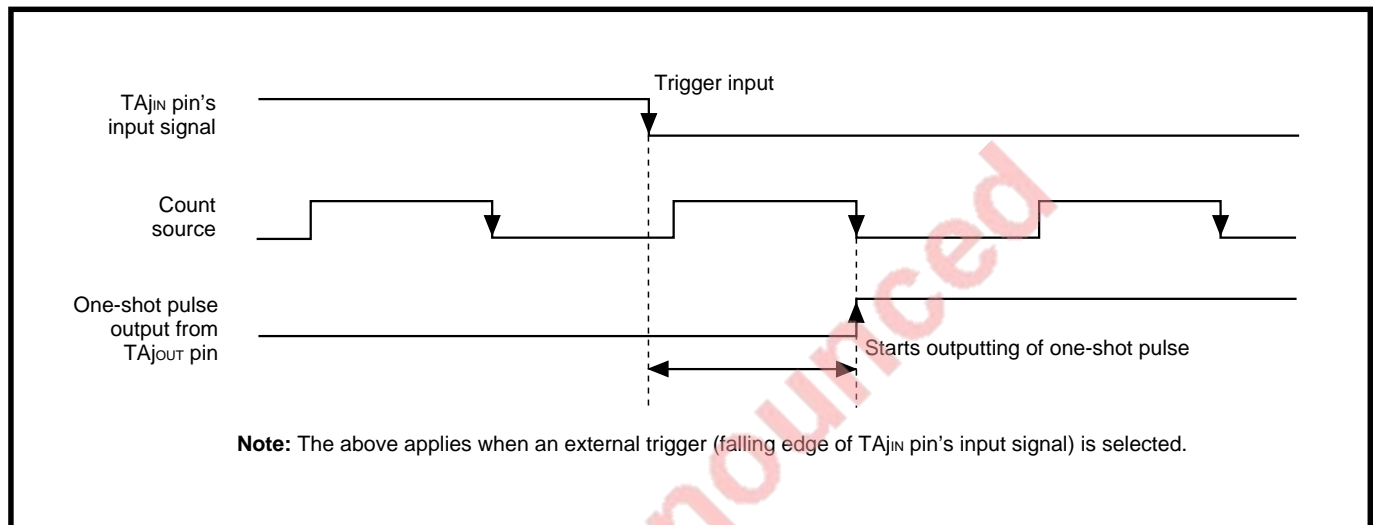

Fig. 8.5.6 Output delay in one-shot pulse output

- When the timer's operating mode is set by one of the following procedures, the timer Aj interrupt request bit is set to "1."
 - When the one-shot pulse mode is selected after reset
 - When the operating mode is switched from the timer mode to the one-shot pulse mode
 - When the operating mode is switched from the event counter mode to the one-shot pulse mode

Accordingly, when using the timer Aj interrupt (interrupt request bit), be sure to clear the timer Aj interrupt request bit to "0" after the above setting.

- Don not set "0000₁₆" to the timer Aj register.

TIMER A

8.6 Pulse width modulation (PWM) mode

8.6 Pulse width modulation (PWM) mode

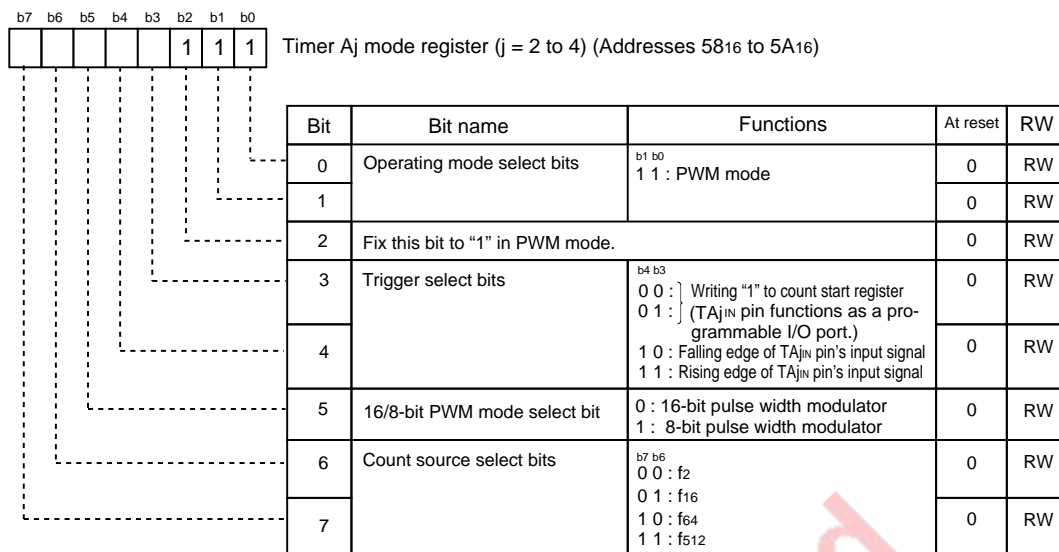

In this mode, the timer continuously outputs pulses which have an arbitrary width. (Refer to “Table 8.6.1.”) Timers A2 to A4 can be used in this mode. Figure 8.6.1 shows the structures of the timer Aj mode registers and timer Aj registers in the PWM mode.

Fig. 8.6.3 Initial setting example for registers relevant to PWM mode (2)

TIMER A

8.6 Pulse width modulation (PWM) mode

8.6.2 Count source

In the PWM mode, the count source select bits (bits 6 and 7 at addresses 58₁₆ to 5A₁₆) select the count source. Table 8.6.2 lists the count source frequency.

Table 8.6.2 Count source frequency

Count source select bits		Count source	Count source frequency		
b7	b6		f(X _{IN}) = 8 MHz	f(X _{IN}) = 16 MHz	f(X _{IN}) = 25 MHz
0	0	f ₂	4 MHz	8 MHz	12.5 MHz
0	1	f ₁₆	500 kHz	1 MHz	1.5625 MHz
1	0	f ₆₄	125 kHz	250 kHz	390.625 kHz
1	1	f ₅₁₂	15625 Hz	31250 Hz	48.8281 kHz

8.6.3 Trigger

When a trigger is generated, the TA_{JOUT} pin starts outputting PWM pulses. An internal or an external trigger can be selected as that trigger.

An internal trigger is selected when the trigger select bits (bits 4 and 3 at addresses 58₁₆ to 5A₁₆) are "00₂" or "01₂"; an external trigger is selected when the bits are "10₂" or "11₂."

A trigger generated during outputting of PWM pulses is invalid and it does not affect the pulse output operation.

(1) When selecting internal trigger

A trigger is generated when "1" is written to the count start bit (address 40₁₆).

(2) When selecting external trigger

A trigger is generated at the falling edge of the TA_{JIN} pin's input signal when bit 3 at addresses 58₁₆ to 5A₁₆ is "0," or at its rising edge when bit 3 is "1." However, the trigger input is accepted only when the count start bit is "1."

When using an external trigger, set the port P5 direction registers' bits which correspond to the TA_{JIN} pins for the input mode.

8.6.4 Operation in PWM mode

- ① When the PWM mode is selected with the operating mode select bits, the TAJ_{OUT} pin outputs “L” level.
- ② When a trigger is generated, the counter (pulse width modulator) starts counting and the TAJ_{OUT} pin outputs a PWM pulse (**Notes 1 and 2**).
- ③ The timer Aj interrupt request bit is set to “1” each time the PWM pulse level goes from “H” to “L.” The interrupt request bit remains set to “1” until the interrupt request is accepted or the interrupt request bit is cleared to “0” by software.
- ④ Each time a PWM pulse has been output for one period, the reload register’s contents are reloaded and the counter continues counting.

The following explains operations of the pulse width modulator.

(1) 16-bit pulse width modulator

When the 16/8-bit PWM mode select bit is set to “0,” the counter operates as a 16-bit pulse width modulator. Figures 8.6.4 and 8.6.5 show operation examples of the 16-bit pulse width modulator.

(2) 8-bit pulse width modulator

When the 16/8-bit PWM mode select bit is set to “1,” the counter is divided into 8-bit halves. Then, the high-order 8 bits operate as an 8-bit pulse width modulator, and the low-order 8 bits operate as an 8-bit prescaler. Figures 8.6.6 and 8.6.7 show operation examples of the 8-bit pulse width modulator.

Notes 1: If a value “0000₁₆” is set into the timer Aj register when the counter operates as a 16-bit pulse width modulator, the pulse width modulator does not operate and the output from the TAJ_{OUT} pin remains “L” level. The timer Aj interrupt request does not occur. Similarly, if a value “00₁₆” is set into the high-order 8 bits of the timer Aj register when the counter operates as an 8-bit pulse width modulator, the same is performed.

- 2:** When the counter operates as an 8-bit pulse width modulator, after a trigger is generated, the TAJ_{OUT} pin outputs “L” level which has the same width as “H” level width of the PWM pulse, which was set. After that, the PWM pulse output starts from the TAJ_{OUT} pin.

TIMER A

8.6 Pulse width modulation (PWM) mode

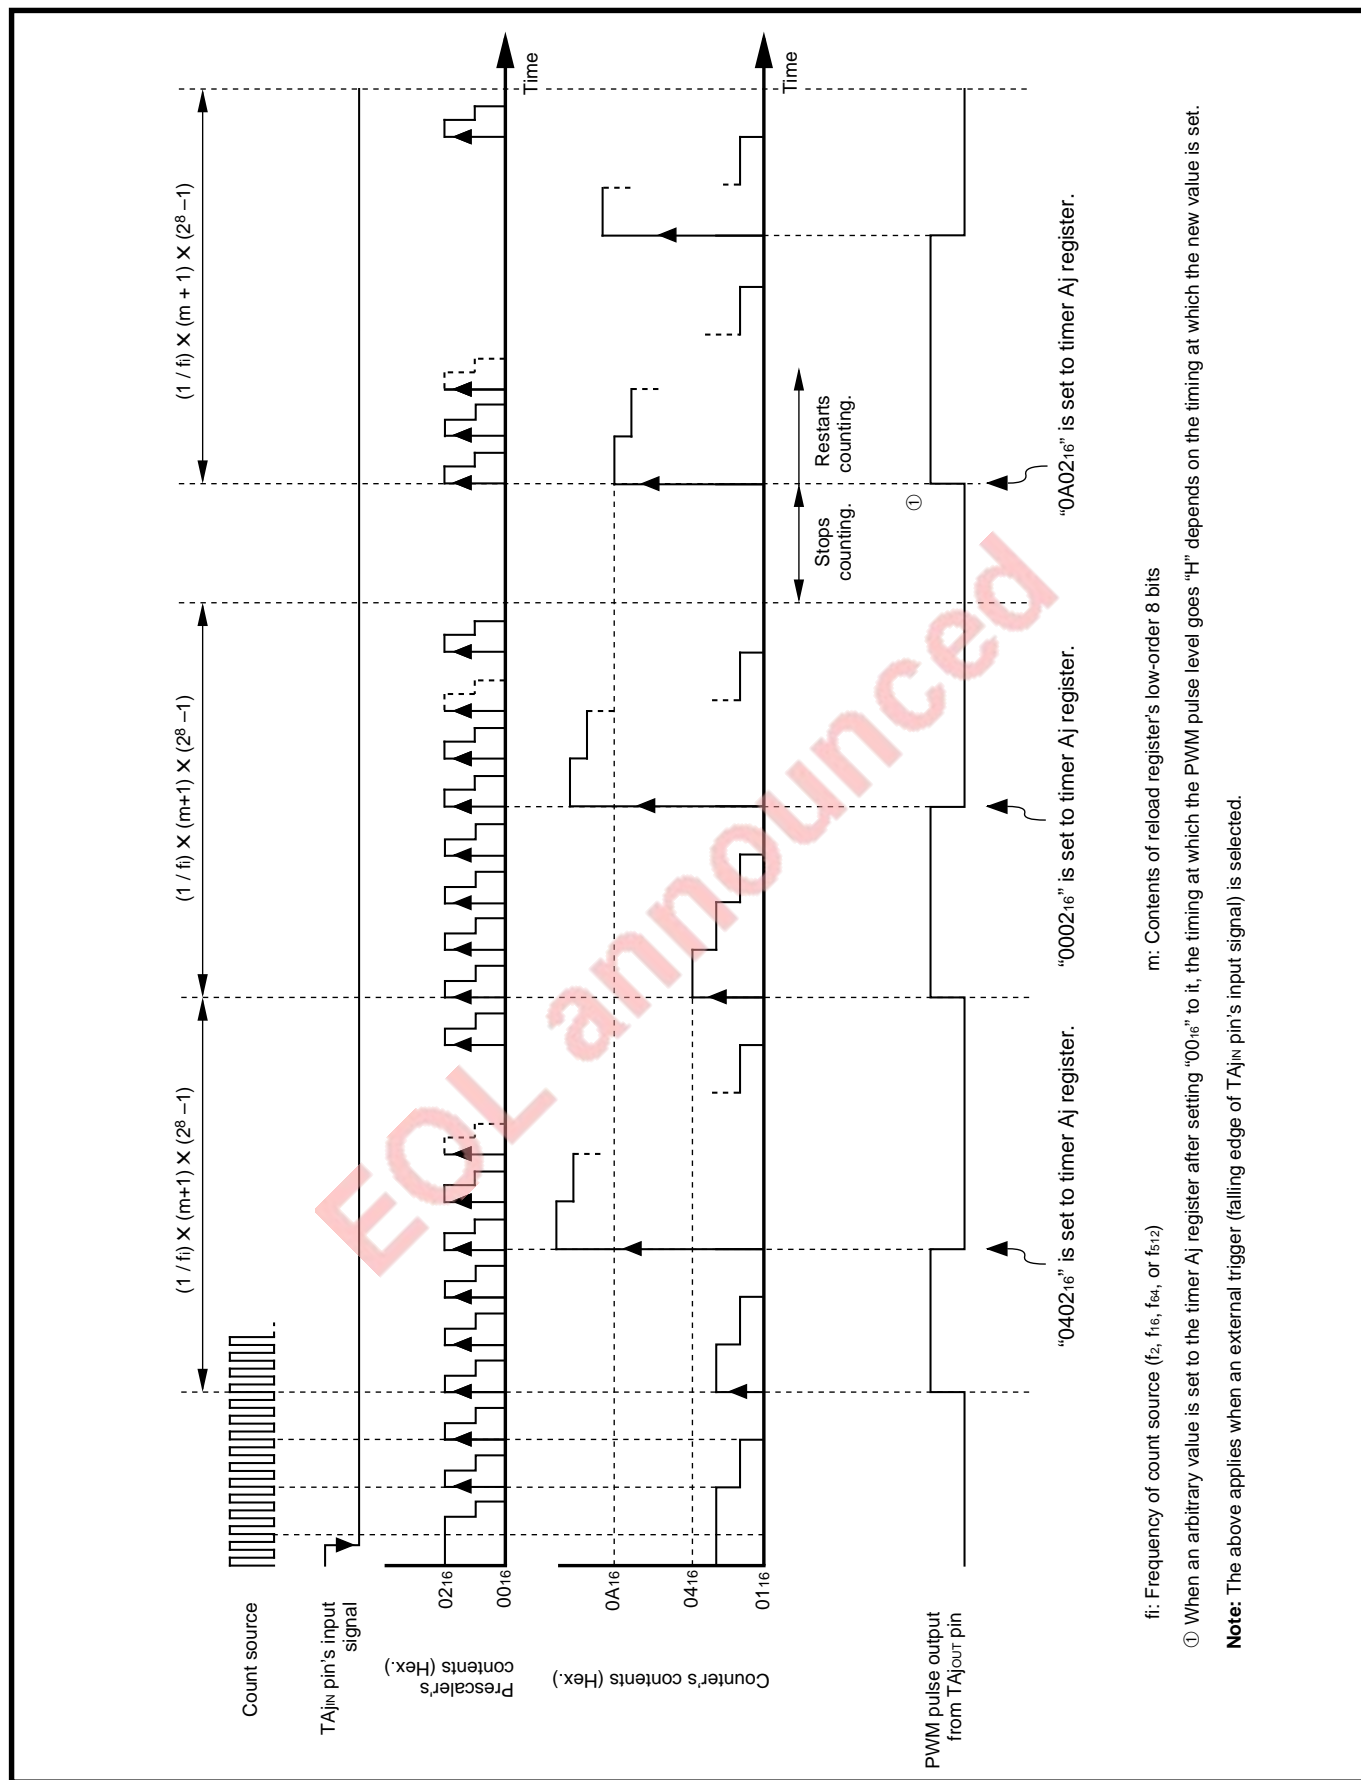

Fig. 8.6.7 Operation example of 8-bit pulse width modulator (when counter value is updated during pulse output)

[Precautions for PWM mode]

1. If the count start bit is cleared to “0” while outputting PWM pulses, the counter stops counting. When the TAJ_{OUT} pin was outputting “H” level at that time, the output level becomes “L” and the timer Aj interrupt request bit is set to “1.” When the TAJ_{OUT} pin was outputting “L” level, the output level does not change and a timer Aj interrupt request does not occur.
2. When the timer’s operating mode is set by one of the following procedures, the timer Aj interrupt request bit is set to “1.”
 - When the PWM mode is selected after reset
 - When the operating mode is switched from the timer mode to the PWM mode
 - When the operating mode is switched from the event counter mode to the PWM mode

Accordingly, when using the timer Aj interrupt (interrupt request bit), be sure to clear the timer Aj interrupt request bit to “0” after the above setting.

[Precautions for pulse period/pulse width measurement (PWM) mode]

TIMER B

9.1 Overview 9.2 Block description

9.1 Overview

Timer B consists of three counters, Timers B0 to B2, each equipped with a 16-bit reload function. Timers B0 to B2 operate independently of one another.

Timer B has three operating modes listed below. Timers B0 and B1 have selective three operating modes listed below. Timer B2 operates only in the timer mode.

(1) Timer mode (Timers B0 to B2)

The timer counts an internally generated count source.

(2) Event counter mode (Timers B0 and B1)

The timer counts an external signal.

(3) Pulse period/Pulse width measurement mode (Timers B0 and B1)

The timer measures an external signal's pulse period or pulse width.

In this chapter, Timer Bi ($i = 0$ to 2) indicates Timers B0 to B2. Timer Bj ($j = 0, 1$) indicates Timers B0 and B1; this is used when the timer B's input/output pins are used etc. (Hereafter, input/output pins are called I/O pins.)

9.2 Block description

Figure 9.2.1 shows the block diagram of Timer B. Explanation of registers relevant to Timer B is described below.

Fig. 9.2.1 Block diagram of Timer B

9.2.1 Counter and reload register (timer Bi register)

Each of timer Bi counter and reload register consists of 16 bits and has the following functions.

(1) Functions in timer mode and event counter mode

Countdown in the counter is performed each time the count source is input. The reload register is used to store the initial value of the counter. When a counter underflow occurs, the reload register's contents are reloaded into the counter.

A value is set to the counter and reload register by writing the value to the timer Bi register. Table 9.2.1 lists the memory assignment of the timer Bi register.

The value written into the timer Bi register when the counting is not in progress is set to the counter and reload register. The value written into the timer Bi register when the counting is in progress is set only to the reload register. In this case, the reload register's updated contents are transferred to the counter when the next underflow occurs. The counter value is read out by reading out the timer Bi register.

Note: When reading from or writing to the timer Bi register, perform it in a unit of 16 bits. For more information about the value obtained by reading the timer Bi register, refer to “[Precautions for timer mode]” and “[Precautions for event counter mode].”

(2) Functions in pulse period/pulse width measurement mode

Countup in the counter is performed each time the count source is input. The reload register is used to retain the pulse period or pulse width measurement result. When a valid edge is input to the TBj_{IN} pin, the counter value is transferred to the reload register. In this mode, the value obtained by reading the timer Bj register is the reload register's contents, so that the measurement result is obtained.

Note: When reading from the timer Bj register, perform it in a unit of 16 bits.

Table 9.2.1 Memory assignment of timer Bi registers

Timer Bi register	High-order byte	Low-order byte
Timer B0 register	Address 51 ₁₆	Address 50 ₁₆
Timer B1 register	Address 53 ₁₆	Address 52 ₁₆
Timer B2 register	Address 55 ₁₆	Address 54 ₁₆

Note: At reset, the contents of the timer Bi register are undefined.

TIMER B

9.2 Block description

9.2.2 Count start register

This register is used to start and stop counting. Each bit of this register corresponds to each timer. Figure 9.2.2 shows the structure of the count start register.

Fig. 9.2.2 Structure of count start register

9.2.3 Timer Bi mode register

Figure 9.2.3 shows the structure of the timer Bi mode register. The operating mode select bits are used to select the operating mode of Timer Bi. Bits 2, 3, and bits 5 to 7 have different functions according to the operating mode. These bits are described in the paragraph of each operating mode.

Fig. 9.2.3 Structure of timer Bi mode register

TIMER B

9.2 Block description

9.2.4 Timer Bi interrupt control register

Figure 9.2.4 shows the structure of the timer Bi interrupt control register. For details about interrupts, refer to “CHAPTER 7. INTERRUPTS.”

Fig. 9.2.4 Structure of timer Bi interrupt control register

(1) Interrupt priority level select bits (bits 2 to 0)

These bits select a timer Bi interrupt’s priority level. When using timer Bi interrupts, select one of the priority levels (1 to 7). When a timer Bi interrupt request occurs, its priority level is compared with the processor interrupt priority level (IPL). The requested interrupt is enabled only when its priority level is higher than the IPL. (However, this applies when the interrupt disable bit (I) = “0.”) To disable timer Bi interrupts, set these bits to “0002” (level 0).

(2) Interrupt request bit (bit 3)

This bit is set to “1” when a timer Bi interrupt request occurs. This bit is automatically cleared to “0” when the timer Bi interrupt request is accepted. This bit can be set to “1” or cleared to “0” by software.

9.2.5 Port P5 direction register

Input pins of Timer Bj are multiplexed with port P5. When using these pins as Timer Bj's input pins, set the corresponding bits of the port P5 direction register to "0" to set these port pins for the input mode. Figure 9.2.5 shows the relationship between port P5 direction register and the Timer Bj's input pins.

Fig. 9.2.5 Relationship between port P5 direction register and Timer Bj's input pins

TIMER B

9.3 Timer mode

9.3 Timer mode

In this mode, the timer counts an internally generated count source. (Refer to “Table 9.3.1.”) Figure 9.3.1 shows the structures of the timer Bi mode register and timer Bi register in the timer mode.

TIMER B

9.3 Timer mode

9.3.3 Operation in timer mode

- ① When the count start bit is set to "1," the counter starts counting of the count source.
- ② When a counter underflow occurs, the reload register's contents are reloaded, and counting continues.
- ③ The timer Bi interrupt request bit is set to "1" at the underflow in ②. The interrupt request bit remains set to "1" until the interrupt request is accepted or the interrupt request bit is cleared to "0" by software.

Figure 9.3.3 shows an example of operation in the timer mode.

Fig. 9.3.3 Example of operation in timer mode

[Precautions for timer mode]

While counting is in progress, by reading the timer Bi register, the counter value can be read out at any timing. However, if the timer Bi register is read at the reload timing shown in Figure 9.3.4, the value "FFFF₁₆" is read out. If reading is performed in the period from when a value is set into the timer Bi register with the counter stopped until the counter starts counting, the set value is correctly read out.

Fig. 9.3.4 Reading timer Bi register

TIMER B

9.4 Event counter mode

9.4 Event counter mode

In this mode, the timer counts an external signal. (Refer to “Table 9.4.1.”) Figure 9.4.1 shows the structures of the timer Bj mode register and the timer Bj register in the event counter mode.

Table 9.4.1 Specifications of event counter mode

Item	Specifications

TIMER B

9.5 Pulse period/Pulse width measurement mode

9.5.2 Count source

In the pulse period/pulse width measurement mode, the count source select bits (bits 6 and 7 at addresses 5B₁₆ and 5C₁₆) select the count source.

Table 9.5.2 lists the count source frequency.

Table 9.5.2 Count source frequency

Count source select bits		Count source	Count source frequency		
b7	b6		f(X _{IN}) = 8 MHz	f(X _{IN}) = 16 MHz	f(X _{IN}) = 25 MHz
0	0	f ₂	4 MHz	8 MHz	12.5 MHz
0	1	f ₁₆	500 kHz	1 MHz	1.5625 MHz
1	0	f ₆₄	125 kHz	250 kHz	390.625 kHz
1	1	f ₅₁₂	15625 Hz	31250 Hz	48.8281 kHz

EOL announced

9.5 Pulse period/Pulse width measurement mode

9.5.3 Operation in pulse period/pulse width measurement mode

- ① When the count start bit is set to “1,” the counter starts counting of the count source.
- ② The counter value is transferred to the reload register when an valid edge of the measurement pulse is detected. (Refer to section “(1) Pulse period/Pulse width measurement.”)
- ③ The counter value is cleared to “0000₁₆” after the transfer in ②, and the counter continues counting.
- ④ The timer Bj interrupt request bit is set to “1” when the counter value is cleared to “0000₁₆” in ③ (**Note**). The interrupt request bit remains set to “1” until the interrupt request is accepted or the interrupt request bit is cleared to “0” by software.
- ⑤ The timer repeats operations ② to ④ above.

Note: No timer Bj interrupt request occurs when the first valid edge is input after the counter starts counting.

(1) Pulse period/Pulse width measurement

The measurement mode select bits (bits 2 and 3 at addresses 5B₁₆ and 5C₁₆) specify whether the pulse period of an external signal is measured or its pulse width is done. Table 9.5.3 lists the relationship between the measurement mode select bits and the pulse period/pulse width measurements. Make sure that the measurement pulse interval from the falling edge to the rising edge, and vice versa are two cycles of the count source or more. Additionally, use software to identify whether the measurement result indicates the “H” level or the “L” level width.

Table 9.5.3 Relationship between measurement mode select bits and pulse period/pulse width measurements

b3	b2	Pulse period/Pulse width measurement	Measurement interval (Valid edges)
0	0	Pulse period measurement	From falling edge to falling edge (Falling edges)
0	1		From rising edge to rising edge (Rising edges)
1	0	Pulse width measurement	From falling edge to rising edge, and vice versa (Falling and rising edges)

(2) Timer Bj overflow flag

A timer Bj interrupt request occurs when a measurement pulse’s valid edge is input or a counter overflow occurs. The timer Bj overflow flag is used to identify the cause of the interrupt request, that is, whether it is an overflow occurrence or a valid edge input.

The timer Bj overflow flag is set to “1” by an overflow. Accordingly, the cause of the interrupt request occurrence is identified by checking the timer Bj overflow flag in the interrupt routine. When a value is written to the timer Bj mode register with the count start bit = “1,” the timer Bj overflow flag is cleared to “0” at the next count timing of the count source

The timer Bj overflow flag is a read-only bit.

Use the timer Bi interrupt request bit to detect the overflow timing. Do not use the timer Bi overflow flag for this detection.

Figure 9.5.3 shows the operation during pulse period measurement. Figure 9.5.4 shows the operation during pulse width measurement.

TIMER B

9.5 Pulse period/Pulse width measurement mode

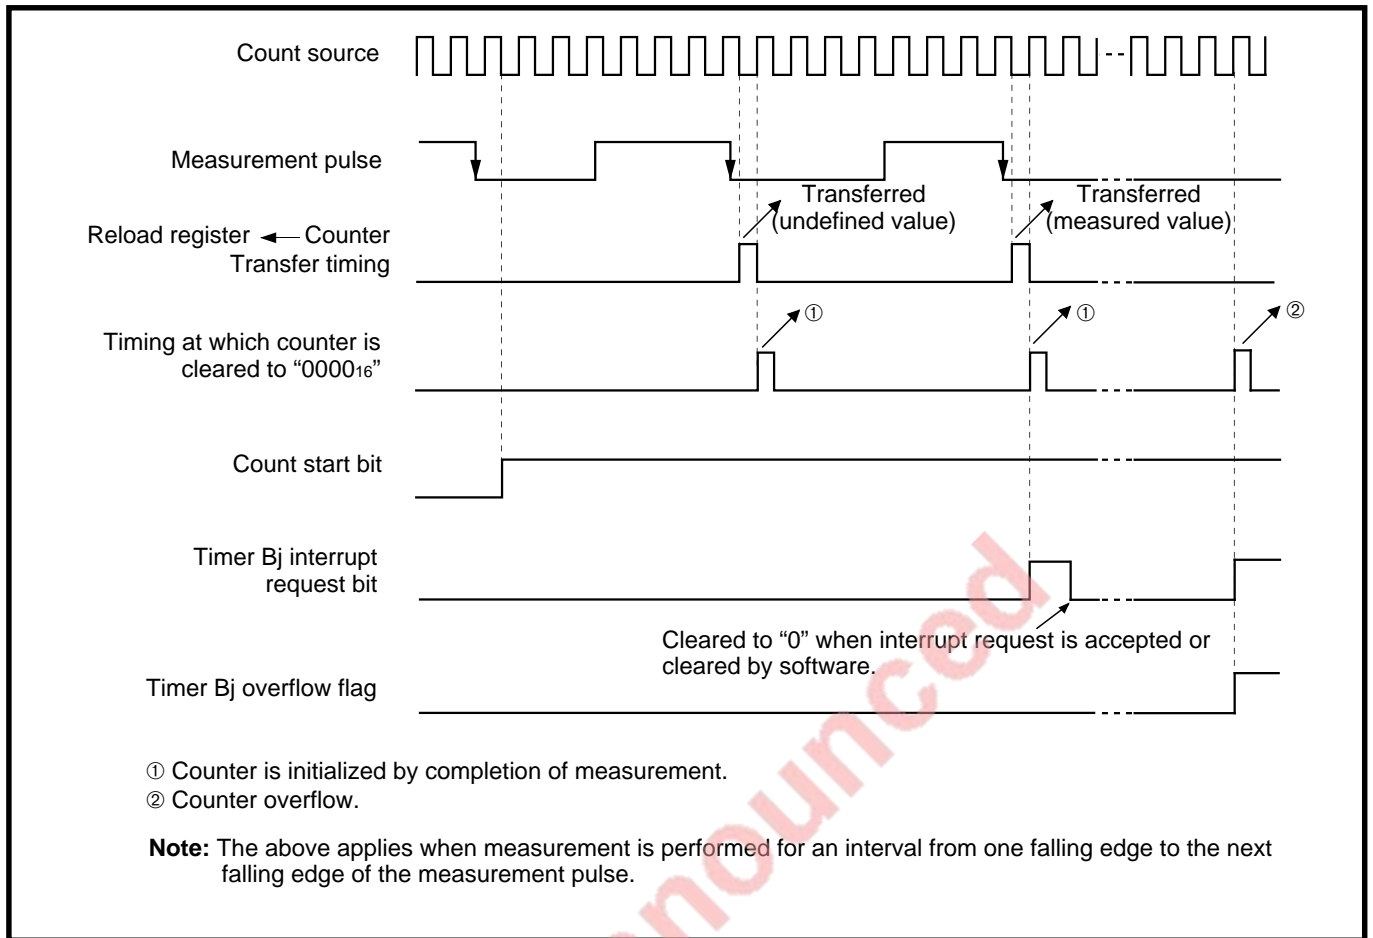

Fig. 9.5.3 Operation during pulse period measurement

Fig. 9.5.4 Operation during pulse width measurement

[Precautions for pulse period/pulse width measurement mode]

1. A timer B_j interrupt request is generated by the following sources:
 - Input of measured pulse's valid edge
 - Counter overflow

When the overflow generates the interrupt request, the timer B_j overflow flag is set to "1."

2. After reset, the timer B_j overflow flag is undefined. When a value is written to the timer B_j mode register with the count start bit = "1," this flag is cleared to "0" at the next count timing of the count source.
3. An undefined value is transferred to the reload register when the first valid edge is input after the counter starts counting. In this case, no timer B_j interrupt request occurs.
4. The counter value at start of counting is undefined. Accordingly, a timer B_j interrupt request may be generated by an overflow immediately after the counter starts counting.
5. If the contents of the measurement mode select bits are changed after the counter starts counting, the timer B_j interrupt request bit is set to "1." When the same value which has been set in these bits are written again, the timer B_j interrupt request bit is not changed, that is, the bit retains the state.
6. If the input signal to the TB_{jIN} pin is affected by noise, etc., the counter may not perform the exact measurement. We recommend to verify, by software, that the measurement values are within a constant range.

REAL-TIME OUTPUT

10.1 Overview

10.2 Block description

10.3 Setting of real-time output

10.4 Real-time output operation

REAL-TIME OUTPUT

10.1 Overview

10.1 Overview

The real-time output has the function of changing the output level of several pins simultaneously at every period of the timer. Figure 10.1.1 shows the block diagram of real-time output per bit. Real-time output has two operating modes described below.

(1) Pulse mode 0

The 8-bit pulse output pins serve for two independent 4-bit outputs. Figure 10.1.2 shows the configuration of real-time output in the pulse mode 0.

(2) Pulse mode 1

The 8-bit pulse output pins serve for a 2-bit and a 6-bit outputs. Figure 10.1.3 shows the configuration of real-time output in the pulse mode 1.

Fig. 10.1.1 Block diagram of real-time output per bit

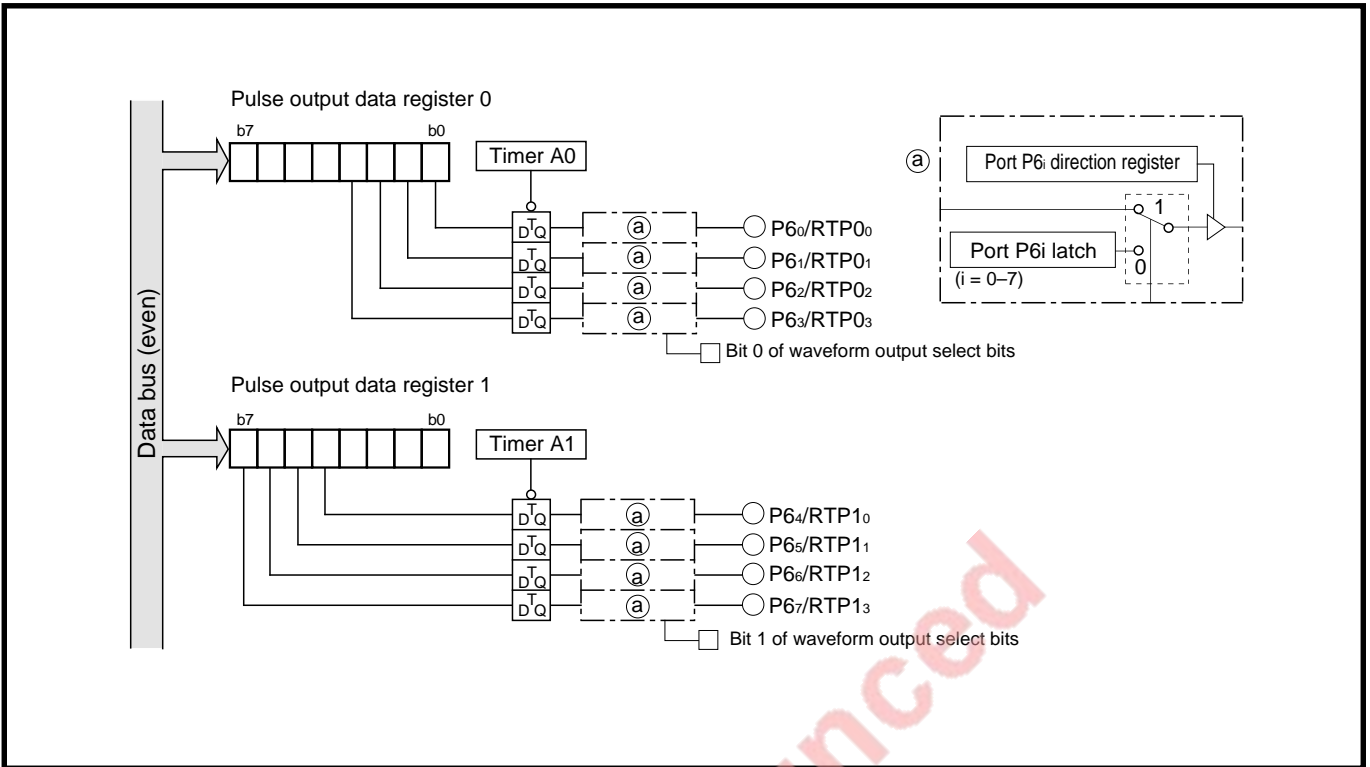

Fig. 10.1.2 Configuration of real-time output in pulse mode 0

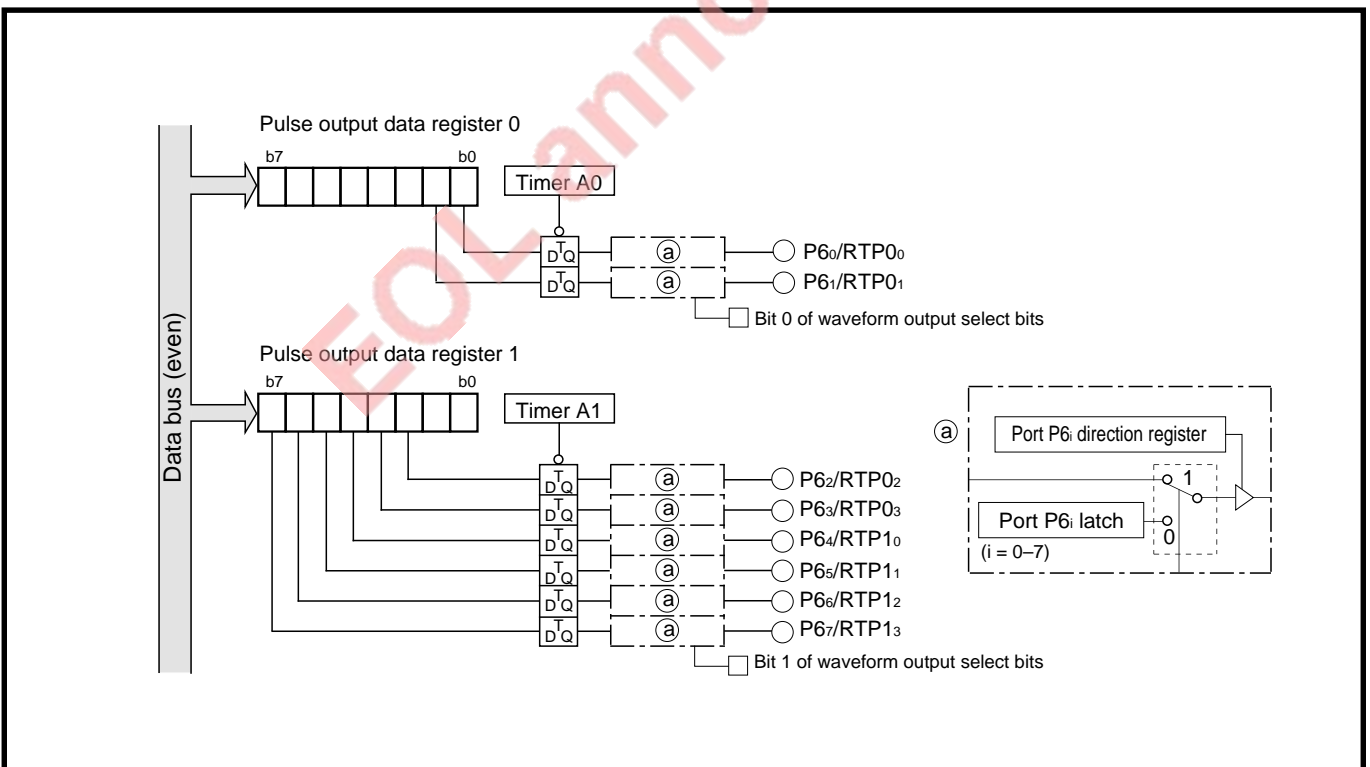

Fig. 10.1.3 Configuration of real-time output in pulse mode 1

REAL-TIME OUTPUT

10.2 Block description

10.2 Block description

Relevant registers to real-time output are described below.

10.2.1 Real-time output control register

Figure 10.2.1 shows the structure of the real-time output control register.

Fig. 10.2.1 Structure of real-time output control register

10.2.2 Pulse output data registers 0 and 1

Figure 10.2.2 shows the structure of the pulse output data registers 0 and 1. The bit position of the RTP0₂ and RTP0₃ pulse output data bits differs according to the pulse mode. Before setting the pulse output data registers 0 and 1, set of the pulse output mode select bit (bit 2 at address 62₁₆).

The data written into the pulse output data registers 0 and 1 is output from the corresponding pulse output pins every underflow of Timers A0 and A1.

Fig. 10.2.2 Structure of pulse output data registers 0 and 1

REAL-TIME OUTPUT

10.2 Block description

10.2.3 Port P6 direction register

The pulse output pins are shared with port P6. When using these pins as pulse output pins of real-time output, set the corresponding bits of the port P6 direction register to “1” to set these ports for the output mode. Figure 10.2.3 shows the relationship between the port P6 direction register and the pulse output pins.

Fig. 10.2.3 Relationship between port P6 direction register and pulse output pins

After reset, the state of the port P6 pins are floated since these pins are in the input mode. The output levels of the pulse output pins are undefined until Timer A0 or A1 underflows first after the data for the timer is written. Because the pulse output data registers 0 and 1 are undefined after reset.

When these conditions should be avoided, follow the procedure “Processing of avoiding undefined output before starting pulse output” in Figures 10.3.1 and 10.3.2.

When reading the port P6 register (address E₁₆), the output values of the real time output pins can be read out.

10.2.4 Timers A0 and A1

The data written into the pulse output registers 0 and 1 is output from the pulse output pins every underflow of Timer A0 or A1. Refer to section “8.3 Timer mode” for the setting of Timers A0 and A1.

10.3 Setting of real-time output

Figures 10.3.1 to 10.3.3 show an initial setting example for registers relevant to the real-time output. Note that when using interrupts, set up to enable the interrupts. For details, refer to “CHAPTER 7. INTERRUPTS.”

Fig. 10.3.1 Initial setting example for registers relevant to real-time output (1)

REAL-TIME OUTPUT

10.3 Setting of real-time output

Fig. 10.3.3 Initial setting example for registers relevant to real-time output (3)

REAL-TIME OUTPUT

10.4 Real-time output operation

10.4 Real-time output operation

- ① When the timer Ai (i = 0, 1) count start bit is set to “1,” the counter starts counting of the count source.
- ② The contents of pulse output data register i are output from the pulse output pins at every underflow of Timer Ai. The timer is reloaded with the contents of the reload register and continues counting.
- ③ The timer Ai interrupt request bit is set to “1” when the counter underflows in ②. The interrupt request bit retains “1” until the interrupt request is accepted or it is cleared by software.
- ④ Write the next output data into the pulse output data register i during the timer Ai interrupt routine or after the recognition of the timer Ai interrupt request occurrence.

Figure 10.4.1 shows an example of real-time output operation.

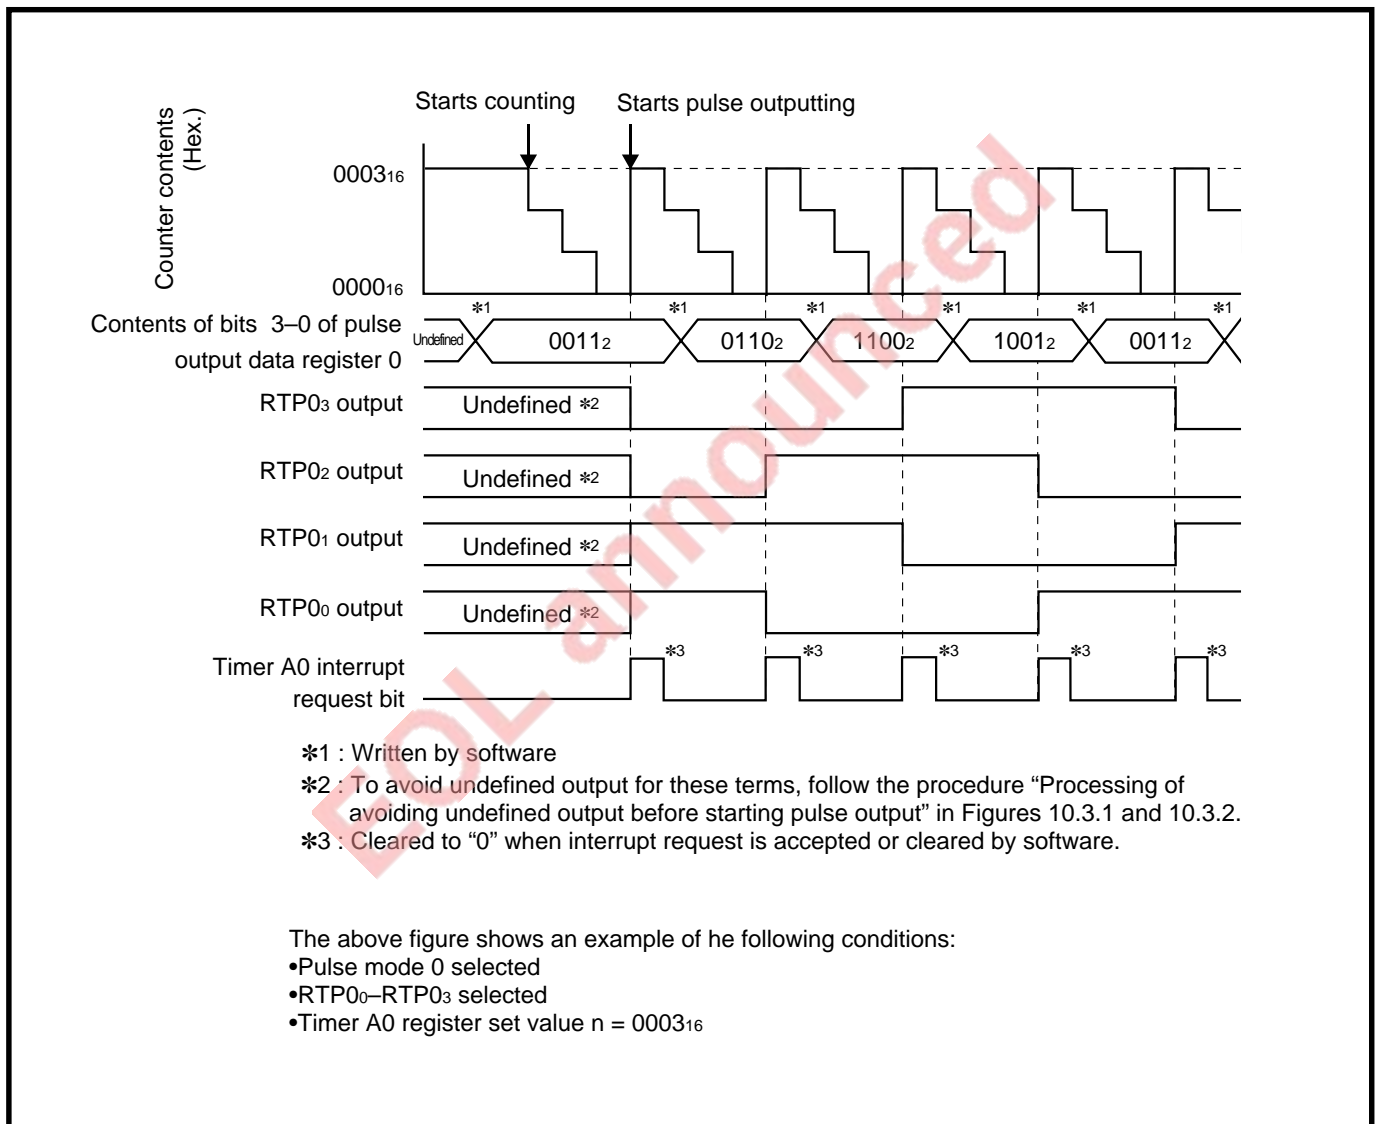

Fig. 10.4.1 Example of real-time output operation

SERIAL I/O

11.1 Overview

11.2 Block description

11.3 Clock synchronous serial I/O mode
[Precautions for clock synchronous
serial I/O mode]

11.4 Clock asynchronous serial I/O
(UART) mode

SERIAL I/O

11.1 Overview

11.1 Overview

Serial I/O consists of 2 channels: UART0 and UART1. They each have a transfer clock generating timer for the exclusive use of them and can operate independently. UART0 and UART1 have the same functions. UARTi (i = 0 and 1) has the following 2 operating modes:

(1) Clock synchronous serial I/O mode

Transmitter and receiver use the same clock as the transfer clock. Transfer data has a length of 8 bits.

(2) Clock asynchronous serial I/O (UART) mode

Transfer rate and transfer data format can arbitrarily be set. The user can select a transfer data length of 7 bits, 8 bits, or 9 bits.

Figure 11.1.1 shows the transfer data formats in each operating mode.

Fig. 11.1.1 Transfer data formats in each operating mode

11.2 Block description

Figure 11.2.1 shows the block diagram of Serial I/O. Registers relevant to Serial I/O are described below.

Fig. 11.2.1 Block diagram of Serial I/O

SERIAL I/O

11.2 Block description

11.2.1 UARTi transmit/receive mode register

Figure 11.2.2 shows the structure of UARTi transmit/receive mode register. The serial I/O mode select bits are used to select a UARTi's operating mode. Bits 4 to 6 are described in section "11.4.2 Transfer data format," and bit 7 is done in section "11.4.8 Sleep mode."

Fig. 11.2.2 Structure of UARTi transmit/receive mode register

(1) Internal/External clock select bit (bit 3)

■ Clock synchronous serial I/O mode

By clearing this bit to “0” in order to select an internal clock, the clock which is selected with the BRG count source select bits (bits 0 and 1 at addresses 34₁₆, 3C₁₆) becomes the count source of the BRGi (described later). The BRGi’s output divided by 2 becomes the transfer clock. Additionally, the transfer clock is output from the CLK_i pin.

By setting this bit to “1” in order to select an external clock, the clock input to the CLK_i pin becomes the transfer clock.

■ UART mode

By clearing this bit to “0” in order to select an internal clock, the clock which is selected with the BRG count source select bits (bits 0 and 1 at addresses 34₁₆, 3C₁₆) becomes the count source of the BRGi (described later). Then, the CLK_i pin functions as a programmable I/O port.

By setting this bit to “1” in order to select an external clock, the clock input to the CLK_i pin becomes the count source of BRGi.

Always in the UART mode, the BRGi’s output divided by 16 becomes the transfer clock.

EOL announced

SERIAL I/O

11.2 Block description

11.2.2 UARTi transmit/receive control register 0

Figure 11.2.3 shows the structure of UARTi transmit/receive control register 0. For bits 0 and 1, refer to section “11.2.1 (1) Internal/External clock select bit (bit 3).”

Fig. 11.2.3 Structure of UARTi transmit/receive control register 0

(1) $\overline{\text{CTS/RTS}}$ select bit (bit 2)

By clearing this bit to “0” in order to select the $\overline{\text{CTS}}$ function, pins P8₀ and P8₄ function as $\overline{\text{CTS}}$ input pins, and the input signal of “L” level to these pins becomes one of the transmission conditions. By setting this bit to “1” in order to select the $\overline{\text{RTS}}$ function, pins P8₀ and P8₄ become $\overline{\text{RTS}}$ output pins. When the receive enable bit (bit 2 at addresses 35₁₆, 3D₁₆) is “0” (reception disabled), the $\overline{\text{RTS}}$ output pin outputs “H” level.

In the clock synchronous serial I/O mode, the output level of the $\overline{\text{RTS}}$ pin becomes “L” when reception conditions are satisfied, and it becomes “H” when reception starts. Note that, when an internal clock is selected (bit 3 at addresses 30₁₆, 38₁₆ = “0”), the $\overline{\text{RTS}}$ output is undefined. Accordingly, do not select the $\overline{\text{RTS}}$ function.

In the clock asynchronous serial I/O mode, the output level of the $\overline{\text{RTS}}$ pin becomes “L” when the receive enable bit is set to “1.” It becomes “H” when reception starts and it becomes “L” when reception is completed.

(2) Transmit register empty flag (bit 3)

This flag is cleared to “0” when the UARTi transmit buffer register’s contents are transferred to the UARTi transmit register. When transmission is completed and the UARTi transmit register becomes empty, this flag is set to “1.”

11.2.3 UARTi transmit/receive control register 1

Figure 11.2.4 shows the structure of UARTi transmit/receive control register 1. For bits 4 to 7, refer to section “11.3.6 Processing on detecting overrun error” and “11.4.7 Processing on detecting error.”

Fig. 11.2.4 Structure of UARTi transmit/receive control register 1

SERIAL I/O

11.2 Block description

(1) Transmit enable bit (bit 0)

By setting this bit to “1,” UARTi enters the transmission enable state. By clearing this bit to “0” during transmission, UARTi enters the transmission disable state after the transmission which is in progress at that time is completed.

(2) Transmit buffer empty flag (bit 1)

This flag is set to “1” when data set in the UARTi transmit buffer register is transferred from the UARTi transmit buffer register to the UARTi transmit register. This flag is cleared to “0” when data is set in the UARTi transmit buffer register.

(3) Receive enable bit (bit 2)

By setting this bit to “1,” UARTi enters the reception enable state. By clearing this bit to “0” during reception, UARTi quits the reception immediately and enters the reception disable state.

(4) Receive complete flag (bit 3)

This flag is set to “1” when data is ready in the UARTi receive register and that is transferred to the UARTi receive buffer register (i.e., when reception is completed). This flag is cleared to “0” when one of the following is performed:

- Reading the low-order byte of the UARTi receive buffer register out
- Clearing the receive enable bit (bit 2) to “0”
- Clearing the serial I/O mode select bits (bits 2 to 0 at addresses 30₁₆, 38₁₆) to “000₂.”

EOL announced

11.2.4 UARTi transmit register and UARTi transmit buffer register

Figure 11.2.5 shows the block diagram for the transmitter; Figure 11.2.6 shows the structure of UARTi transmit buffer register.

Fig. 11.2.5 Block diagram for transmitter

Fig. 11.2.6 Structure of UARTi transmit buffer register

SERIAL I/O

11.2 Block description

Transmit data is set into the UARTi transmit buffer register. Set the transmit data into the low-order byte of this register when the microcomputer operates in the clock synchronous serial I/O mode or when a 7-bit or 8-bit length of transfer data is selected in the UART mode. When a 9-bit length of transfer data is selected in the UART mode, set the transmit data into the UARTi transmit buffer register as follows:

- Bit 8 of the transmit data into bit 0 of high-order byte of this register.
- Bits 7 to 0 of the transmit data into the low-order byte of this register.

The transmit data which is set in the UARTi transmit buffer register is transferred to the UARTi transmit register when the transmission conditions are satisfied, and then it is output from the TxDi pin synchronously with the transfer clock. The UARTi transmit buffer register becomes empty when the data which is set in the UARTi transmit buffer register is transferred to the UARTi transmit register. Accordingly, the user can set the next transmit data.

When quitting the transmission which is in progress and setting the UARTi transmit buffer register again, follow the procedure described below:

- ① Clear the serial I/O mode select bits (bits 2 to 0 at addresses 30_{16} , 38_{16}) to "000₂" (Serial I/O disabled).
- ② Set the serial I/O mode select bits again.
- ③ Set the transmit enable bit (bit 0 at addresses 35_{16} , $3D_{16}$) to "1" (transmission enabled) and set transmit data in the UARTi transmit buffer register.

EOL announced

11.2.5 UARTi receive register and UARTi receive buffer register

Figure 11.2.7 shows the block diagram for the receiver; Figure 11.2.8 shows the structure of UARTi receive buffer register.

Fig. 11.2.7 Block diagram for receiver

Fig. 11.2.8 Structure of UARTi receive buffer register

SERIAL I/O

11.2 Block description

The UARTi receive register is used to convert serial data which is input to the RxDi pin into parallel data. This register takes in the signal input to the RxDi pin in a unit of 1 bit synchronously with the transfer clock. The UARTi receive buffer register is used to read out receive data. When reception is completed, the receive data which is taken in the UARTi receive register is automatically transferred to the UARTi receive buffer register. Note that the contents of the UARTi receive buffer register is updated when the next data is ready in the UARTi receive register before the data which has been transferred to the UARTi receive buffer register is read out. (i.e., an overrun error occurs.)

The UARTi receive buffer register is initialized by setting the receive enable bit (bit 2 at addresses 35₁₆, 3D₁₆) to "1" after clearing it to "0."

Figure 11.2.9 shows the contents of the UARTi receive buffer register when reception is completed.

Fig. 11.2.9 Contents of UARTi receive buffer register when reception is completed

11.2.6 UARTi baud rate register (BRGi)

The UARTi baud rate register (BRGi) is an 8-bit timer exclusively used for UARTi to generate a transfer clock. It has a reload register. Assuming that the value set in the BRGi is “n” ($n = \text{“00”}_{16}$ to “FF”_{16}), the BRGi divides the count source frequency by $(n + 1)$.

In the clock synchronous serial I/O mode, the BRGi is valid when an internal clock is selected, and the BRGi’s output divided by 2 becomes the transfer clock. In the UART mode, the BRGi is always valid, and the BRGi’s output divided by 16 becomes the transfer clock.

The data which is written to the UARTi baud rate register (BRGi) is written to both the timer and the reload register whether transmission/reception is in progress or not. Accordingly, writing to these register must be performed while transmission/reception is stopped.

Figure 11.2.10 shows the structure of the UARTi baud rate register (BRGi); Figure 11.2.11 shows the block diagram of transfer clock generating section.

Fig. 11.2.10 Structure of UARTi baud rate register (BRGi)

Fig. 11.2.11 Block diagram of transfer clock generating section

SERIAL I/O

11.2 Block description

11.2.7 UARTi transmit interrupt control and UARTi receive interrupt control registers

When using UARTi, 2 types of interrupts, which are UARTi transmit and UARTi receive interrupts, can be used. Each interrupt has its corresponding interrupt control register. Figure 11.2.12 shows the structure of UARTi transmit interrupt control and UARTi receive interrupt control registers.

For details about interrupts, refer to “CHAPTER 7. INTERRUPTS.”

Fig. 11.2.12 Structure of UARTi transmit interrupt control and UARTi receive interrupt control registers

(1) Interrupt priority level select bits (bits 0 to 2)

These bits select a priority level of the UARTi transmit interrupt or UARTi receive interrupt. When using UARTi transmit/receive interrupts, select one of the priority levels (1 to 7). When a UARTi transmit/receive interrupt request occurs, its priority level is compared with the processor interrupt priority level (IPL). The requested interrupt is enabled only when its priority level is higher than the IPL. (However, this applies when the interrupt disable flag (I) = “0.”) To disable UARTi transmit/receive interrupts, set these bits to “000₂” (level 0).

(2) Interrupt request bit (bit 3)

The UARTi transmit interrupt request bit is set to “1” when data is transferred from the UARTi transmit buffer register to the UARTi transmit register. The UARTi receive interrupt request bit is set to “1” when data is transferred from the UARTi receive register to the UARTi receive buffer register. (However, when an overrun error occurs, it does not change.)

Each interrupt request bit is automatically cleared to “0” when its corresponding interrupt request is accepted. This bit can be set to “1” or “0” by software.

11.2.8 Port P8 direction register

I/O pins of UART_i are multiplexed with port P8. When using pins P8₂ and P8₆ as serial data input pins (RxD_i), set the corresponding bits of the port P8 direction register to “0” to set these pins for the input mode. When using pins P8₀, P8₁, P8₃ to P8₅ and P8₇ as I/O pins ($\overline{\text{CTS}}_i/\overline{\text{RTS}}_i$, CLK_i, TxD_i) of UART_i, these pins are forcibly set as I/O pins of UART_i regardless of the port P8 direction register’s contents. Figure 11.2.13 shows the relationship between the port P8 direction register and UART_i’s I/O pins. For details, refer to the description of each operating mode.

Fig. 11.2.13 Relationship between port P8 direction register and UART_i’s I/O pins

SERIAL I/O

11.3 Clock synchronous serial I/O mode

11.3 Clock synchronous serial I/O mode

Table 11.3.1 lists the performance overview in the clock synchronous serial I/O mode, and Table 11.3.2 lists the functions of I/O pins in this mode.

Table 11.3.1 Performance overview in clock synchronous serial I/O mode

Item		Functions
Transfer data format		Transfer data has a length of 8 bits. LSB first
Transfer rate	When selecting internal clock	BRGi's output divided by 2
	When selecting external clock	Maximum 5 Mbps
Transmit/Receive control		CTS function or RTS function can be selected by software.

Table 11.3.2 Functions of I/O pins in clock synchronous serial I/O mode

Pin name	Functions	Method of selection
TxD _i (P8 ₃ , P8 ₇) (Note)	Serial data output	(Dummy data is output when performing only reception.)
RxD _i (P8 ₂ , P8 ₆)	Serial data input	Port P8 direction register*1's corresponding bit = "0" (Can be used as an I/O port when performing only transmission.)
CLK _i (P8 ₁ , P8 ₅)	Transfer clock output	Internal/External clock select bit*2 = "0"
	Transfer clock input	Internal/External clock select bit = "1"
CTS/RTS _i (P8 ₀ , P8 ₄)	CTS input	CTS/RTS select bit*3 = "0"
	RTS output	CTS/RTS select bit = "1"

Port P8 direction register*1: address 14₁₆

Internal/External clock select bit*2: bit 3 at addresses 30₁₆, 38₁₆

CTS/RTS select bit*3: bit 2 at addresses 34₁₆, 3C₁₆

Note: The TxD_i pin outputs "H" level until transmission starts after UART_i's operating mode is selected.

11.3.1 Transfer clock (Synchronizing clock)

Data transfer is performed synchronously with the transfer clock. For the transfer clock, the user can select whether to generate the transfer clock internally or to input it from the external.

The transfer clock is generated by operation of the transmit control circuit. Accordingly, even when performing only reception, set the transmit enable bit to “1,” and set dummy data in the UARTi transmit buffer register in order to make the transmit control circuit active.

(1) Internal generation of transfer clock

The count source selected with the BRG count source select bits is divided by the BRGi, and the BRGi output is further divided by 2. This is the transfer clock. The transfer clock is output from the CLKi pin.

[Setting for relevant registers]

- Select an internal clock (bit 3 at addresses 30₁₆, 38₁₆ = “0”).
- Select the BRGi's count source (bits 0 and 1 at addresses 34₁₆, 3C₁₆)
- Set “division value – 1” (= n; 00₁₆ to FF₁₆) to the BRGi (addresses 31₁₆, 39₁₆).

$$\text{Transfer clock's frequency} = \frac{f_i}{2(n+1)} \quad f_i: \text{Frequency of BRGi's count source } (f_2, f_{16}, f_{64}, f_{512})$$

- Enable transmission (bit 0 at addresses 35₁₆, 3D₁₆ = “1”).
- Set data to the UARTi transmit buffer register (addresses 32₁₆, 3A₁₆)

[Pin's state]

- A transfer clock is output from the CLKi pin.
- Serial data is output from the TxDi pin. (Dummy data is output when performing only reception.)

(2) Input of transfer clock from the external

A clock input from the CLKi pin is the transfer clock.

[Setting for relevant registers]

- Select an external clock (bit 3 at addresses 30₁₆, 38₁₆ = “1”).
- Enable transmission (bit 0 at addresses 35₁₆, 3D₁₆ = “1”).
- Set data to the UARTi transmit buffer register (addresses 32₁₆, 3A₁₆).

[Pin's state]

- A transfer clock is input from the CLKi pin.
- Serial data is output from the TxDi pin. (Dummy data is output when performing only reception.)

SERIAL I/O

11.3 Clock synchronous serial I/O mode

11.3.2 Method of transmission

Figure 11.3.1 shows an initial setting example for relevant registers when transmitting. Transmission is started when all of the following conditions (① to ③) are satisfied. When an external clock is selected, satisfy conditions ① to ③ with the following precondition satisfied.

<Precondition>

The CLK_i pin's input is at "H" level

Note: When an internal clock is selected, the above precondition is ignored.

- ① Transmission is enabled (transmit enable bit = "1").
- ② Transmit data is present in the UART_i transmit buffer register (transmit buffer empty flag = "0")
- ③ The CTS_i pin's input is at "L" level (when the CTS function selected).

Note: When the CTS function is not selected, condition ③ is ignored.

By connecting the $\overline{\text{RTS}}_i$ pin (receiver side) and $\overline{\text{CTS}}_i$ pin (transmitter side), the timing of transmission and that of reception can be matched. For details, refer to section "11.3.5 Receive operation."

When using interrupts, it is necessary to set the relevant registers to enable interrupts. For details, refer to "CHAPTER 7. INTERRUPTS."

Figure 11.3.2 shows writing data after start of transmission, and Figure 11.3.3 shows detection of transmit completion.

EOL announced

11.3 Clock synchronous serial I/O mode

Fig. 11.3.1 Initial setting example for relevant registers when transmitting

11.3.3 Transmit operation

When the transmit conditions described in section “11.3.2 Method of transmission” are satisfied in the case of selecting an internal clock, a transfer clock is generated and the following operations are automatically performed after 1 cycle of the transfer clock has passed. When the transmit conditions are satisfied and the external clock is input to the CLKi pin in the case of selecting an external clock, the following operations are automatically performed.

- The UARTi transmit buffer register’s contents are transferred to the UARTi transmit register.
- The transmit buffer empty flag is set to “1.”
- The transmit register empty flag is cleared to “0.”
- 8 transfer clocks are generated (when an internal clock is selected).
- A UARTi transmit interrupt request occurs, and the interrupt request bit is set to “1.”

The transmit operations are described below:

- ① Data in the UARTi transmit register is transmitted from the TxDi pin synchronously with the falling edge of the transfer clock.
- ② This data is transmitted bit by bit sequentially beginning with the least significant bit.
- ③ When 1-byte data has been transmitted, the transmit register empty flag is set to “1.” This indicates the completion of transmission.

Figure 11.3.4 shows the transmit operation.

When an internal clock is selected, when the transmit conditions for the next data are satisfied at completion of the transmission, the transfer clock is generated continuously. Accordingly, when performing transmission continuously, set the next transmit data to the UARTi transmit buffer register during transmission (when the transmit register empty flag = “0”). When the transmit conditions for the next data are not satisfied, the transfer clock stops at “H” level.

Figures 11.3.5 and 11.3.6 show examples of transmit timing.

Fig. 11.3.4 Transmit operation

SERIAL I/O

11.3 Clock synchronous serial I/O mode

Fig. 11.3.5 Example of transmit timing (when selecting internal clock, selecting CTS function)

Fig. 11.3.6 Example of transmit timing (when selecting internal clock, not selecting CTS function)

11.3.4 Method of reception

Figures 11.3.7 and 11.3.8 show initial setting examples for relevant registers when receiving. Reception is started when all of the following conditions (① to ③) are satisfied. When an external clock is selected, satisfy conditions ① to ③ with the following precondition satisfied.

<Precondition>

The CLK_i pin's input is at "H" level.

Note: When an internal clock is selected, the above precondition is ignored.

- ① Reception is enabled (receive enable bit = "1").
- ② Transmission is enabled (transmit enable bit = "1").
- ③ Dummy data is present in the UART_i transmit buffer register (transmit buffer empty flag = "0")

By connecting the $\overline{\text{RTS}}_i$ pin (receiver side) and $\overline{\text{CTS}}_i$ pin (transmitter side), the timing of transmission and that of reception can be matched. For details, refer to section "11.3.5 Receive operation."

When using interrupts, it is necessary to set the relevant registers to enable interrupts. For details, refer to "CHAPTER 7. INTERRUPTS."

Figure 11.3.9 shows processing after receive completion.

SERIAL I/O

11.3 Clock synchronous serial I/O mode

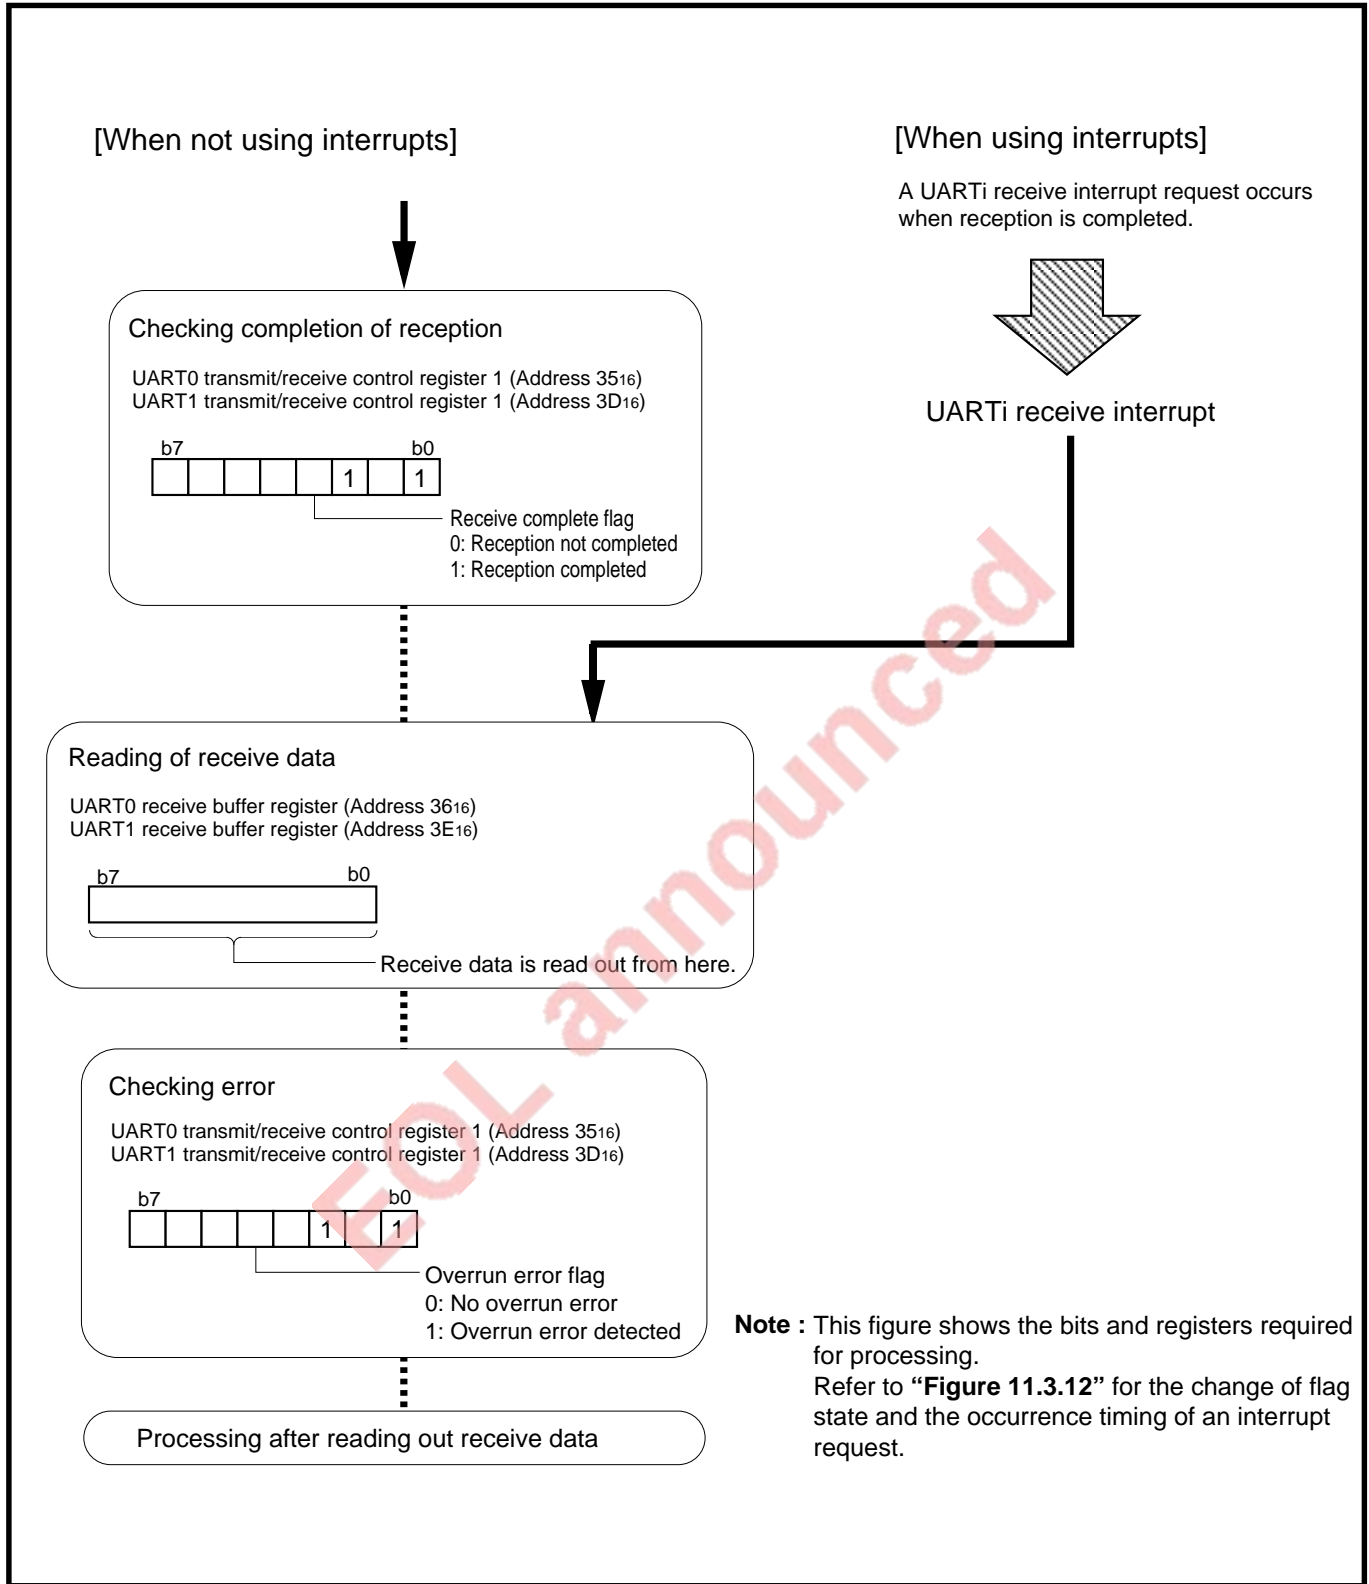

Fig. 11.3.9 Processing after receive completion

11.3.5 Receive operation

In the case of selecting an internal clock, when the receive conditions described in section “11.3.4 Method of reception” are satisfied, a transfer clock is generated and the reception is started after 1 cycle of the transfer clock has passed.

In the case of selecting an external clock, when the receive conditions are satisfied, the UART_i enters the receive enable state and reception is started by input of an external clock to the CLK_i pin.

In the case of selecting an external clock and the RTS function, when the UART_i enters the receive enable state, the RTS_i pin's output level becomes “L” to inform the transmitter side that reception is enabled. When reception is started, the RTS_i pin's output level becomes “H.” Accordingly, by connecting the RTS_i pin to the CTS_i pin of the transmitter side, the timing of transmission and that of reception can be matched. When an internal clock is selected, do not use the RTS function. It is because the RTS output becomes undefined. Figure 11.3.10 shows a connection example.

The receive operations are described below:

- ① The input signal of the RxD_i pin is taken into the most significant bit of the UART_i receive register synchronously with the rising edge of the transfer clock.
- ② The contents of the UART_i receive register are shifted by 1 bit to the right.
- ③ Steps ① and ② are repeated at each rising edge of the transfer clock.
- ④ When 1-byte data is prepared in the UART_i receive register, the contents of this register are transferred to the UART_i receive buffer register.
- ⑤ Simultaneously with step ④, the receive complete flag is set to “1,” and a UART_i receive interrupt request occurs and its interrupt request bit is set to “1.”

The receive complete flag is cleared to “0” when the low-order byte of the UART_i receive buffer register is read out. The RTS_i pin outputs “H” level until the receive conditions are next satisfied (when selecting the RTS function). Figure 11.3.11 shows the receive operation, and Figure 11.3.12 shows an example of receive timing (when selecting an external clock).

SERIAL I/O

11.3 Clock synchronous serial I/O mode

Fig. 11.3.11 Receive operation

Fig. 11.3.12 Example of receive timing (when selecting external clock)

11.3.6 Processing on detecting overrun error

In the clock synchronous serial I/O mode, an overrun error can be detected.

An overrun error occurs when the next data is prepared in the UARTi receive register with the receive complete flag = "1" (data is present in the UARTi receive buffer register) and next data is transferred to the UARTi receive buffer register, in other words, when the next data is prepared before reading out the contents of the UARTi receive buffer register. When an overrun error occurs, the next receive data is written into the UARTi receive buffer register, and the UARTi receive interrupt request bit is not changed. An overrun error is detected when data is transferred from the UARTi receive register to the UARTi receive buffer register and the overrun error flag is set to "1." The overrun error flag is cleared to "0" by clearing the serial I/O mode select bits to "000₂" or clearing the receive enable bit to "0."

When an overrun error occurs during reception, initialize the overrun error flag and the UARTi receive buffer register before performing reception again. When it is necessary to perform retransmission owing to an overrun error which occurs in the receiver side, set the UARTi transmit buffer register again before starting transmission again.

The method of initializing the UARTi receive buffer register and that of setting the UARTi transmit buffer register again are described below.

(1) Method of initializing UARTi receive buffer register

- ① Clear the receive enable bit to "0" (Reception disabled).
- ② Set the receive enable bit to "1" again (Reception enabled).

(2) Method of setting UARTi transmit buffer register again

- ① Clear the serial I/O mode select bits to "000₂" (Serial I/O invalid).
- ② Set the serial I/O mode select bits to "001₂" again.
- ③ Set the transmit enable bit to "1" (Transmission enabled), and set the transmit data to the UARTi transmit buffer register.

SERIAL I/O

11.3 Clock synchronous serial I/O mode

[Precautions for clock synchronous serial I/O mode]

1. The transfer clock is generated by operation of the transmit control circuit. Accordingly, even when performing only reception, transmit operation (setting for transmission) must be performed. In this case, dummy data is output from the TxD_i pin.
2. When receiving, simultaneously set the receive enable bit and the transmit enable bit to "1."
3. When receiving data, write dummy data to the low-order byte of the UART_i transmit buffer register for each reception of 1-byte data.
4. When selecting an external clock, satisfy the following 3 conditions with the input to the CLK_i pin = "H" level.

<When transmitting>

- ① Set the transmit enable bit to "1."
- ② Write transmit data to the UART_i transmit buffer register.
- ③ Input "L" level to the CTS_i pin (when selecting the CTS function).

<When receiving>

- ① Set the receive enable bit to "1."
- ② Set the transmit enable bit to "1."
- ③ Write dummy data to the UART_i transmit buffer register.

11.4 Clock asynchronous serial I/O (UART) mode

11.4 Clock asynchronous serial I/O (UART) mode

Table 11.4.1 lists the performance overview in the UART mode, and Table 11.4.2 lists the functions of I/O pins in this mode.

Table 11.4.1 Performance overview in UART mode

Item		Functions
Transfer data format	Start bit	1 bit
	Character bit (Transfer data)	7 bits, 8 bits, or 9 bits
	Parity bit	0 bit or 1 bit (Odd or even can be selected.)
	Stop bit	1 bit or 2 bits
Transfer rate	When selecting internal clock	BRGi's output divided by 16
	When selecting external clock	Maximum 312.5 kbps
Error detection		4 types (Overrun, Framing, Parity, and Summing) Presence of error can be detected only by checking error sum flag.

Table 11.4.2 Functions of I/O pins in UART mode

Pin name	Functions	Method of selection
TxD _i (P8 ₃ , P8 ₇) (Note 1)	Serial data output	(Cannot be used as a programmable I/O port even when performing only reception.)
RxD _i (P8 ₂ , P8 ₆)	Serial data input	Port P8 direction register*1's corresponding bit = "0" (Can be used as a programmable I/O port when performing only transmission.)
CLK _i (P8 ₁ , P8 ₅)	Programmable I/O port	Internal/External clock select bit*2 = "0"
	BRGi's count source input	Internal/External clock select bit = "1"
CTS _i /RTS _i (P8 ₀ , P8 ₄) (Note 2)	CTS input	CTS/RTS function select bit*3 = "0"
	RTS output	CTS/RTS function select bit = "1"

Port P8 direction register*1: address 14₁₆

Internal/External clock select bit*2: bit 3 at addresses 30₁₆, 38₁₆

CTS/RTS select bit*3: bit 2 at addresses 34₁₆, 3C₁₆

Notes 1: The TxD_i pin outputs "H" level while transmission is not performed after selecting UARTi's operating mode.

2: The CTS_i/RTS_i pin can be used as an input port when performing only reception and not using the RTS function (when selecting CTS function).

SERIAL I/O

11.4 Clock asynchronous serial I/O (UART) mode

11.4.1 Transfer rate (Frequency of transfer clock)

The transfer rate is determined by the BRGi (addresses 31₁₆, 39₁₆).

When setting “n” into BRGi, BRGi divides the count source frequency by (n + 1). The BRGi’s output is further divided by 16, and the resultant clock becomes the transfer clock. Accordingly, “n” is expressed by the following formula.

$$n = \frac{F}{16 \times B} - 1$$

n: Value set in BRGi (00₁₆ to FF₁₆)

F: BRGi's count source frequency (Hz)

B: Transfer rate (bps)

An internal clock or an external clock can be selected as the BRGi's count source with the internal/external clock select bit (bit 3 at addresses 30₁₆, 38₁₆). When an internal clock is selected, the clock selected with the BRG count source select bits (bits 0 and 1 at addresses 34₁₆, 3C₁₆) becomes the BRGi's count source. When an external clock is selected, the clock input to the CLK_i pin becomes the BRGi's count source. Set the same transfer rate for both transmitter and receiver sides. Tables 11.4.3 and 11.4.4 list the setting examples of transfer rate.

Table 11.4.3 Setting examples of transfer rate (1)

11.4 Clock asynchronous serial I/O (UART) mode

11.4.2 Transfer data format

The transfer data format can be selected from formats shown in Figure 11.4.1. Bits 4 to 6 at addresses 30₁₆ and 38₁₆ select the transfer data format. (Refer to “Figure 11.2.2.”) Set the same transfer data format for both transmitter and receiver sides.

Figure 11.4.2 shows an example of transfer data format. Table 11.4.5 lists each bit in transmit data.

Fig. 11.4.1 Transfer data format

Fig. 11.4.2 Example of transfer data format

Table 11.4.5 Each bit in transmit data

Name	Functions
ST Start bit	“L” signal equivalent to 1 character bit which is added immediately before the character bits. It indicates start of data transmission.
DATA Character bit	Transmit data which is set in the UARTi transmit buffer register.
PAR Parity bit	A signal that is added immediately after the character bits in order to improve data reliability. The level of this signal changes according to selection of odd/even parity in such a way that the sum of “1”s in this bit and character bits is always an odd or even number.
SP Stop bit	“H” level signal equivalent to 1 or 2 character bits which is added immediately after the character bits (or parity bit when parity is enabled). It indicates finish of data transmission.

SERIAL I/O

11.4 Clock asynchronous serial I/O (UART) mode

11.4.3 Method of transmission

Figure 11.4.3 shows an initial setting example for relevant registers when transmitting.

The difference due to selection of transfer data length (7 bits, 8 bits, or 9 bits) is only that data length. When selecting a 7- or 8-bit data length, set the transmit data into the low-order byte of the UART_i transmit buffer register. When selecting a 9-bit data length, set the transmit data into the low-order byte and bit 0 of the high-order byte.

Transmission is started when all of the following conditions (① to ③) are satisfied:

- ① Transmit is enabled (transmit enable bit = "1").
- ② Transmit data is present in the UART_i transmit buffer register (transmit buffer empty flag = "0").
- ③ The CTS_i pin's input is at "L" level (when the CTS function selected).

Note: When the CTS function is not selected, condition ③ is ignored.

By connecting the $\overline{\text{RTS}}_i$ pin (receiver side) and $\overline{\text{CTS}}_i$ pin (transmitter side), the timing of transmission and that of reception can be matched. For details, refer to section "11.4.6 Receive operation."

When using interrupts, it is necessary to set the relevant registers to enable interrupts. For details, refer to "CHAPTER 7. INTERRUPTS."

Figure 11.4.4 shows writing data after start of transmission, and Figure 11.4.5 shows detection of transmit completion.

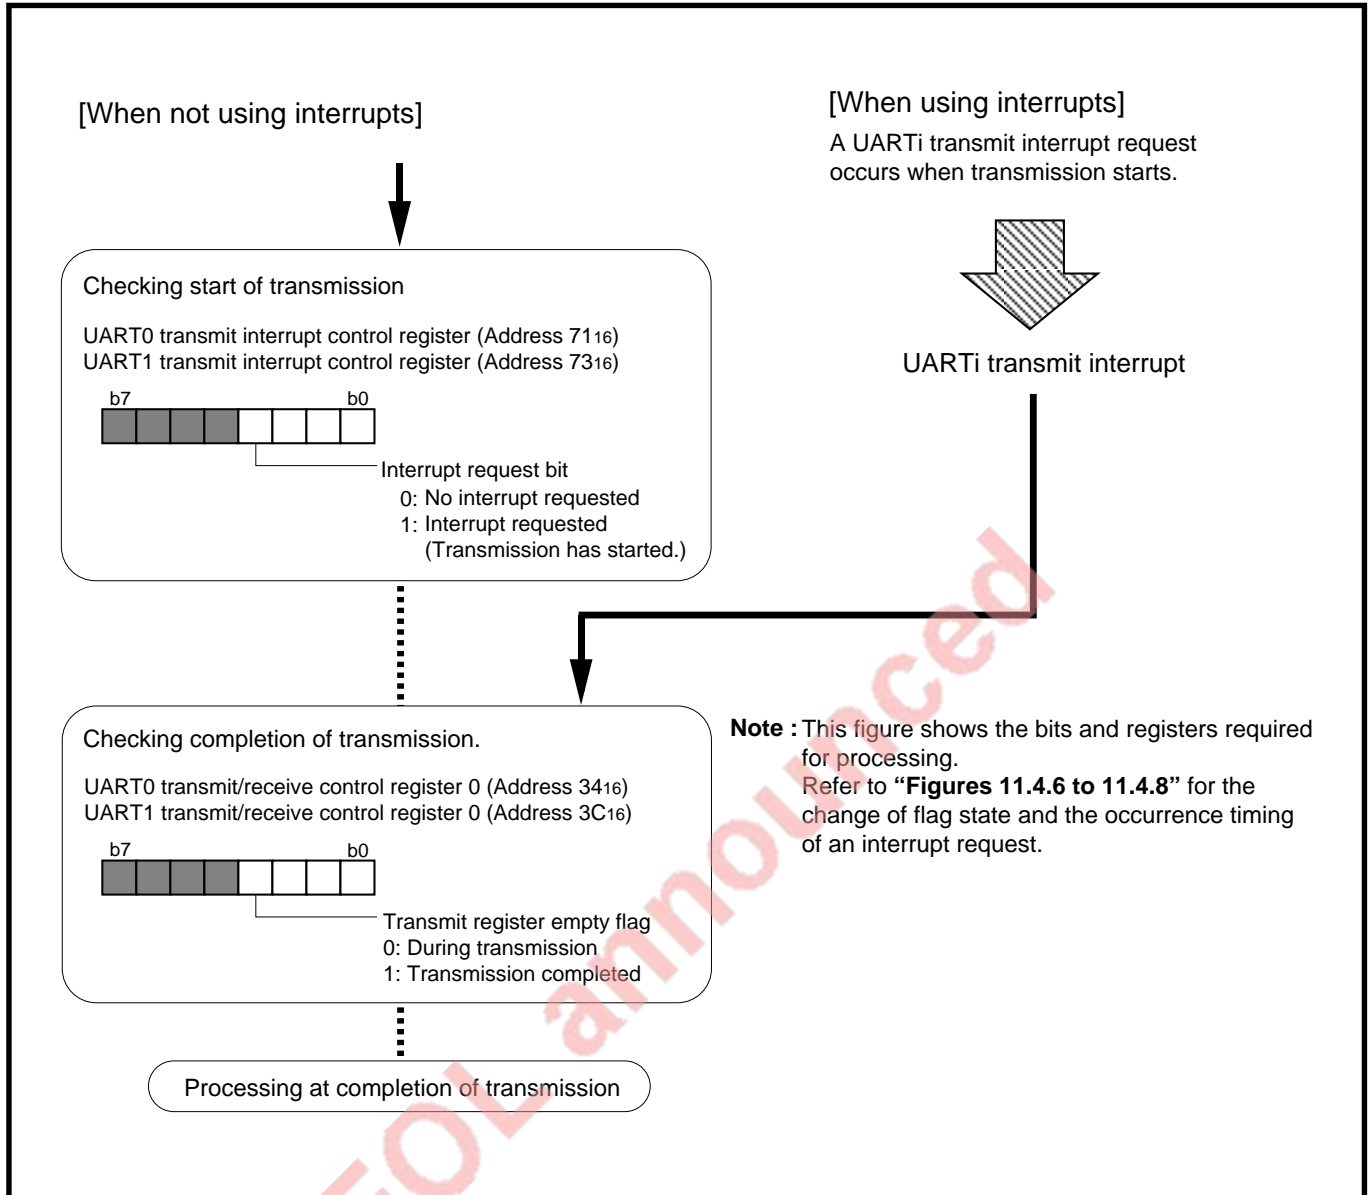

Fig. 11.4.5 Detection of transmit completion

SERIAL I/O

11.4 Clock asynchronous serial I/O (UART) mode

11.4.4 Transmit operation

When the receive conditions described in section “11.4.3 Method of transmission” are satisfied, a transfer clock is generated and the following operations are automatically performed after 1 cycle of the transfer clock has passed.

- The UART_i transmit buffer register's contents are transferred to the UART_i transmit register.
- The transmit buffer empty flag is set to “1.”
- The transmit register empty flag is cleared to “0.”
- A UART_i transmit interrupt request occurs and the interrupt request bit is set to “1.”

The transmit operations are described below:

- ① Data in the UART_i transmit register is transmitted from the TxD_i pin.
- ② This data is transmitted bit by bit sequentially in order of ST→DATA (LSB)→•••→DATA (MSB)→PAR→SP according to the transfer data format.
- ③ The transmit register empty flag is set to “1” at the center of the stop bit (or the second stop bit when selecting 2-stop bits), indicating completion of transmission. Additionally, whether the transmit conditions for the next data are satisfied or not is examined.

When the transmit conditions for the next data are satisfied in step ③, the start bit is generated following the stop bit, and the next data is transmitted. When performing transmission continuously, set the next transmit data in the UART_i transmit buffer register during transmission (when the transmit register empty flag = “0”). When the transmit conditions for the next data are not satisfied, the TxD_i pin outputs “H” level and the transfer clock stops.

Figures 11.4.6 and 11.4.7 show examples of transmit timing when the transfer data length = 8 bits, and Figure 11.4.8 shows an example of transmit timing when the transfer data length = 9 bits.

SERIAL I/O

11.4 Clock asynchronous serial I/O (UART) mode

Fig. 11.4.8 Example of transmit timing when transfer data length = 9 bits (when parity disabled, selecting 2 stop bits, not selecting CTS function)

11.4.5 Method of reception

Figure 11.4.9 shows an initial setting example for relevant registers when receiving. Reception is started when all of the following conditions (① and ②) are satisfied:

- ① Reception is enabled (receive enable bit = "1").
- ② The start bit is detected.

By connecting the $\overline{\text{RTS}}_i$ pin (receiver side) and $\overline{\text{CTS}}_i$ pin (transmitter side), the timing of transmission and that of reception can be matched. For details, refer to section "11.4.6 Receive operation."

When using interrupts, it is necessary to set the relevant registers to enable interrupts. For details, refer to "CHAPTER 7. INTERRUPTS."

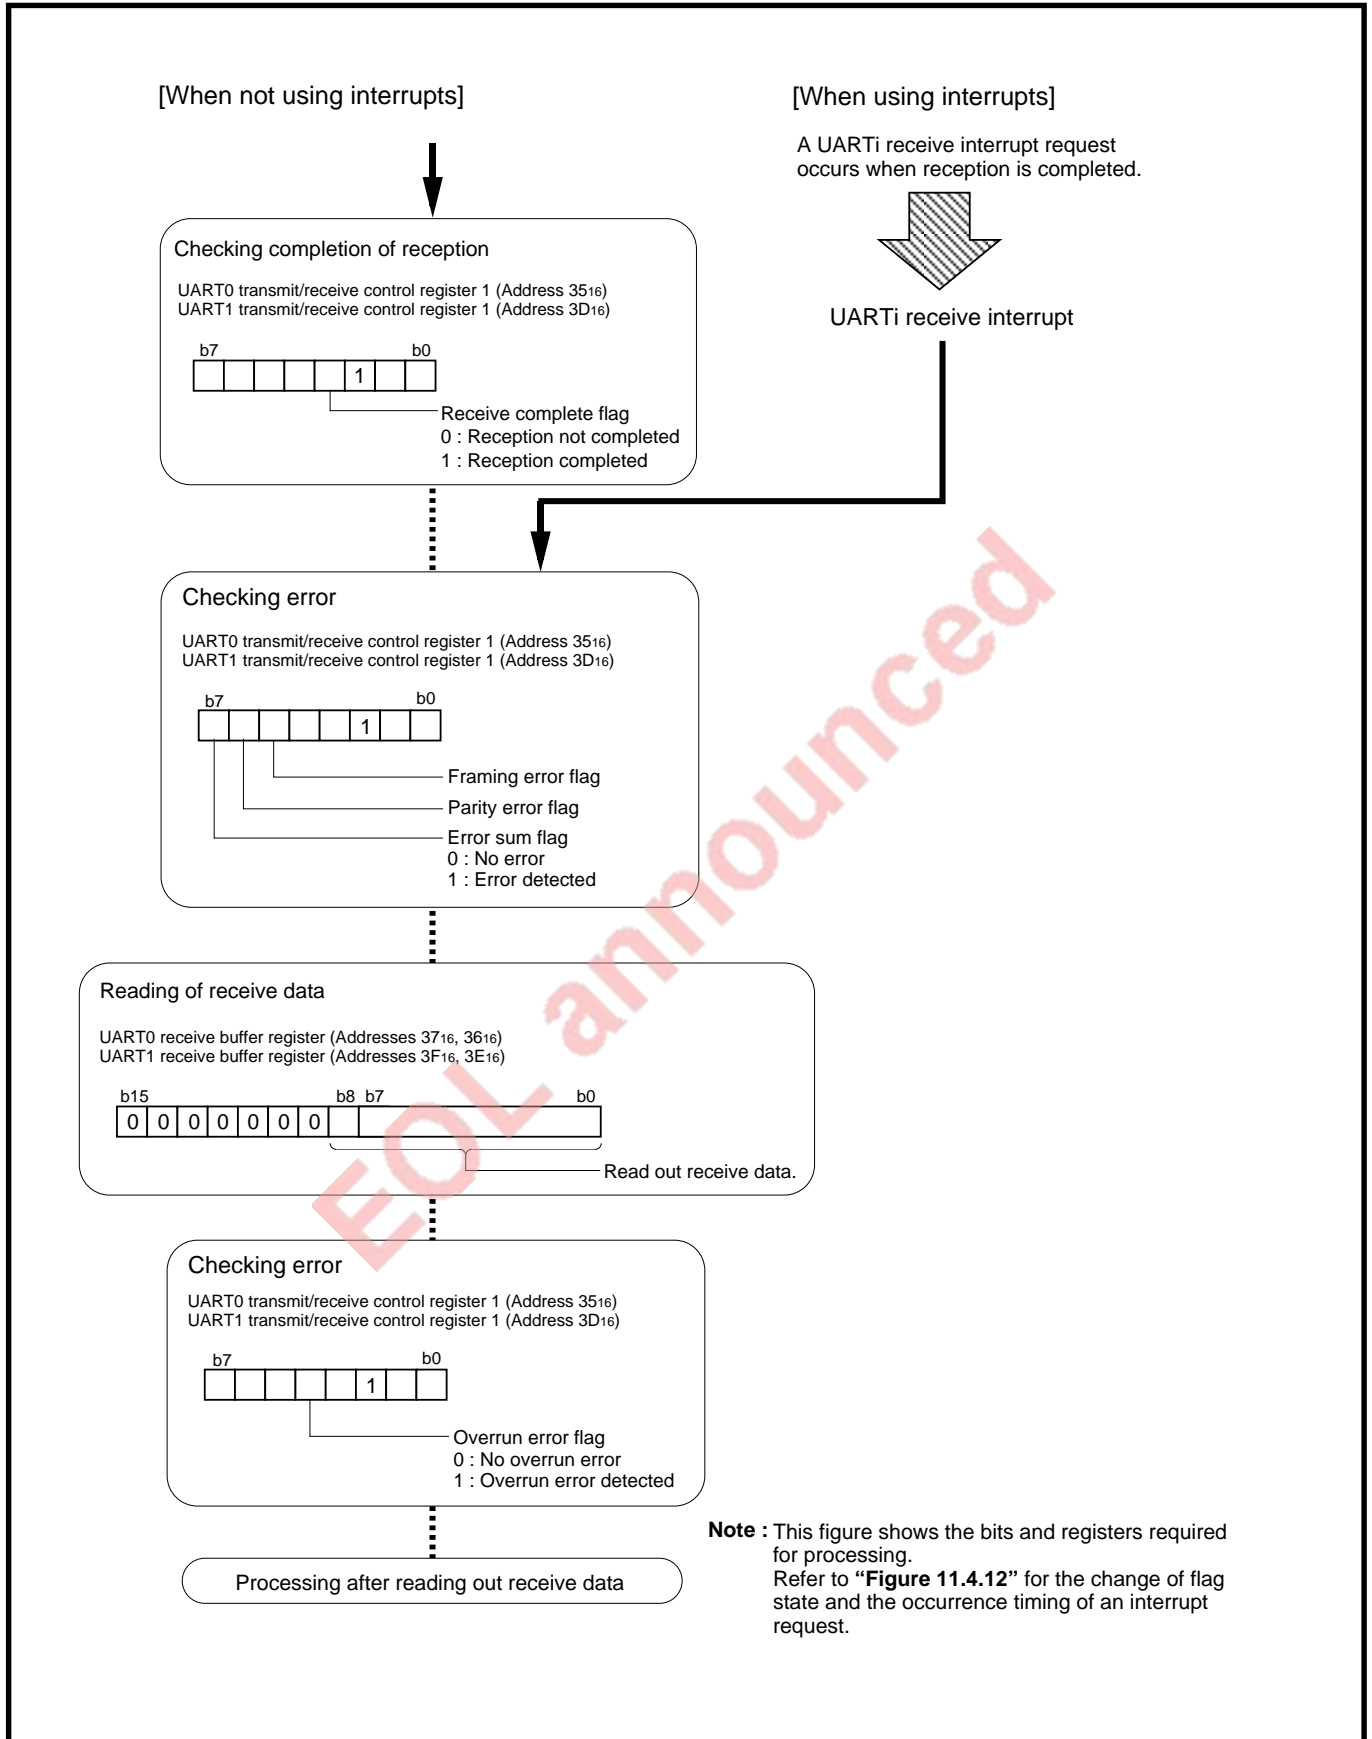

Fig. 11.4.10 Processing after receive completion

SERIAL I/O

11.4 Clock asynchronous serial I/O (UART) mode

11.4.6 Receive operation

When the receive enable bit is set to “1,” the UART_i enters the receive enable state. After this, reception starts when ST is detected and a transfer clock is generated.

In the case of selecting the $\overline{\text{RTS}}_i$ function, when the reception is enabled, the $\overline{\text{RTS}}_i$ pin’s output level becomes “L” to inform the transmitter side that reception is enabled. When reception is started, the $\overline{\text{RTS}}_i$ pin’s output level becomes “H.” Accordingly, by connecting the $\overline{\text{RTS}}_i$ pin to the CTS_i pin of the transmitter side, the timing of transmission and that of reception can be matched. Figure 11.4.11 shows an connection example.

The receive operation is described below.

- ① The input signal of the RxD_i pin is taken into the most significant bit of the UART_i receive register synchronously with the transfer clock’s rising edge.
- ② The contents of the UART_i receive register are shifted by 1 bit to the right.
- ③ Steps ① and ② are repeated at each rising edge of the transfer clock.
- ④ When one set of data has been prepared, in other words, when the shift has been performed several times according to the selected data format, the UART_i receive register’s contents are transferred to the UART_i receive buffer register.
- ⑤ Simultaneously with step ④, the receive complete flag is set to “1.” Additionally, a UART_i receive interrupt request occurs and its interrupt request bit is set to “1.”

The receive complete flag is cleared to “0” when the low-order byte of the UART_i receive buffer register is read out. The $\overline{\text{RTS}}_i$ pin’s output level becomes “L” simultaneously with step ⑤ (when selecting the $\overline{\text{RTS}}_i$ function). Figure 11.4.12 shows an example of receive timing when the transfer data length = 8 bits.

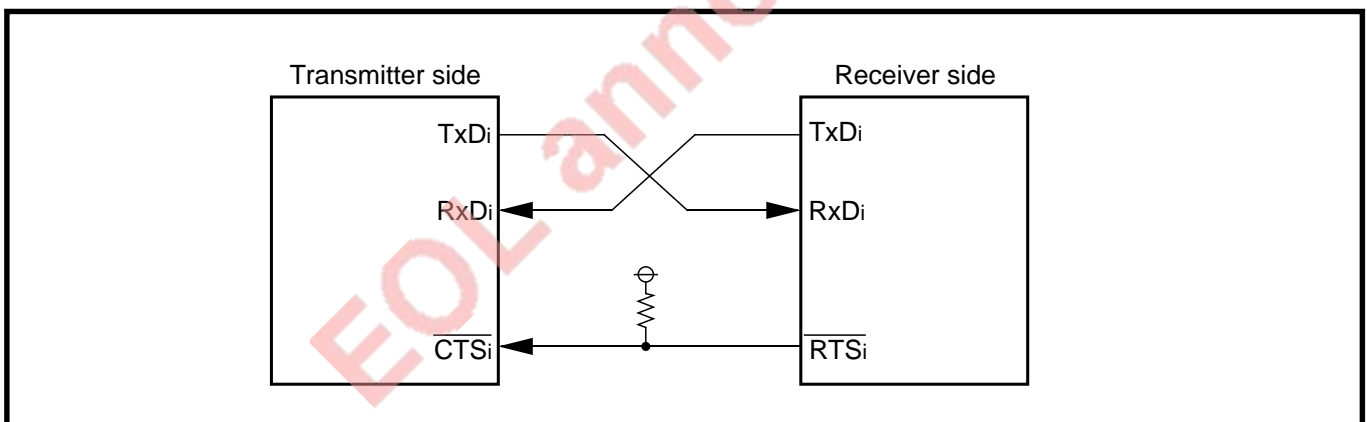

Fig. 11.4.11 Connection example

11.4 Clock asynchronous serial I/O (UART) mode

Fig. 11.4.12 Example of receive timing when transfer data length = 8 bits (when parity disabled, selecting 1 stop bit, selecting RTS function)

SERIAL I/O

11.4 Clock asynchronous serial I/O (UART) mode

11.4.7 Processing on detecting error

In the UART mode, 3 types of errors can be detected. Each error can be detected when the data in the UARTi receive register is transferred to the UARTi receive buffer register, and the corresponding error flag is set to "1." When any error occurs, the error sum flag is set to "1." Accordingly, presence of errors can be judged by using the error sum flag.

Table 11.4.6 lists conditions for setting each error flag to "1" and method for clearing it to "0."

Table 11.4.6 Conditions set to "1" and method cleared to "0" for each error flag

Error flag	Conditions for being set to "1"	Method for being cleared to "0"
Overrun error flag	When the next data is prepared in the UARTi receive register with the receive complete flag = "1" (i.e., data is present in the UARTi receive buffer register). In other words, when the next data is prepared before the contents of the UARTi receive buffer register are read out. (Note) [UARTi receive interrupt request bit is not changed.]	<ul style="list-style-type: none">•Clear the serial I/O mode select bits to "000₂."•Clear the receive enable bit to "0."
Framing error flag	When the number of detected stop bits does not match the set number of stop bits. [UARTi receive interrupt request bit is set to "1."]	<ul style="list-style-type: none">•Clear the serial I/O mode select bits to "000₂."•Clear the receive enable bit to "0."•Read out the low-order byte of the UARTi receive buffer register.
Parity error flag	When the sum of "1"s in the parity bit and character bits does not match the set number of "1"s. [UARTi receive interrupt request bit is set to "1."]	<ul style="list-style-type: none">•Clear the serial I/O mode select bits to "000₂."•Clear the receive enable bit to "0."•Read out the low-order byte of the UARTi receive buffer register.
Error sum flag	When 1 or more errors listed above occur.	<ul style="list-style-type: none">•Clear the all error flags, which are overrun, framing and parity error flags.

Note: The next data is written into the UARTi receive buffer register.

When an error occurs during reception, initialize the error flag and the UARTi receive buffer register, and then perform reception again. When it is necessary to perform retransmission owing to an error which occurs in the receiver side during transmission, set the UARTi transmit buffer register again, and then restarts transmission.

The method of initializing the UARTi receive buffer register and that of setting the UARTi transmit buffer register again are described below.

(1) Method of initializing UARTi receive buffer register

- ① Clear the receive enable bit to "0" (reception disabled).
- ② Set the receive enable bit to "1" again (reception enabled).

(2) Method of setting UARTi transmit buffer register again

- ① Clear the serial I/O mode select bits to "000₂" (serial I/O invalid).
- ② Set the serial I/O mode select bits again.
- ③ Set the transmit enable bit to "1" (transmission enabled), and set the transmit data to the UARTi transmit buffer register.

11.4 Clock asynchronous serial I/O (UART) mode

11.4.8 Sleep mode

This mode is used to transfer data between the specified microcomputers, which are connected by using UARTi. The sleep mode is selected by setting the sleep select bit (bit 7 at addresses 30₁₆, 38₁₆) to “1” when receiving.

In the sleep mode, receive operation is performed when the MSB (D₈ when the transfer data is 9 bits length, D₇ when it is 8 bits length, D₆ when it is 7 bits length) of the receive data is “1.” Receive operation is not performed when the MSB is “0.” (The UARTi receive register’s contents are not transferred to the UARTi receive buffer register. Additionally, the receive complete flag and error flags do not change and a UARTi receive interrupt request does not occur.)

The following shows an usage example of the sleep mode when the transfer data is 8 bits length.

- ① Set the same transfer data format for the master and slave microcomputers. Select the sleep mode for the slave microcomputers.
- ② Transmit data, which has “1” in bit 7 and the address of the slave microcomputer to be communicated in bits 0 to 6, from the master microcomputer to all slave microcomputers.
- ③ All slave microcomputers receive data of step ②. (At this time, a UARTi receive interrupt request occurs.)
- ④ For all slave microcomputers, check in the interrupt routine whether bits 0 to 6 in the receive data match their own addresses.
- ⑤ For the slave microcomputer of which address matches bits 0 to 6 in the receive data, terminate the sleep mode. (Do not terminate the sleep mode for the other slave microcomputers.)
By performing steps ② to ⑤, “ the microcomputer which performs transfer” is specified.
- ⑥ Transmit data, which has “0” in bit 7, from the master microcomputer. (Only the microcomputer specified in steps ② to ⑤ can receive this data. The other microcomputers do not receive this data.)
- ⑦ By repeating step ⑥, transfer can be performed between two specific microcomputers continuously. When communicating with another microcomputer, perform steps ② to ⑤ in order to specify the new slave microcomputer.

Figure 12.2.1 shows the block diagram of the A-D converter. Registers relevant to the A-D converter are described below.

Fig. 12.2.1 Block diagram of A-D converter

A-D CONVERTER

12.2 Block description

12.2.1 A-D control register

Figure 12.2.2 shows the structure of the A-D control register. The A-D operation mode select bit selects the operation mode of the A-D converter. The other bits are described below.

Fig. 12.2.2 Structure of A-D control register

(1) Analog input select bits (bits 2 to 0)

These bits are used to select an analog input pin in the one-shot mode and repeat mode. Pins which are not selected as analog input pins function as programmable I/O ports.

These bits must be set again when the user switches the A-D operation mode to the one-shot mode or repeat mode after A-D conversion is performed in the single sweep mode or repeat sweep mode.

(2) Trigger select bit (bit 5)

This bit is used to select the source of trigger occurrence. (Refer to section “(3) A-D conversion start bit.”)

(3) A-D conversion start bit (bit 6)

● When internal trigger is selected

Setting this bit to “1” generates a trigger, causing the A-D converter to start operating. Clearing this bit to “0” causes the A-D converter to stop operating.

In the one-shot mode or single sweep mode, this bit is cleared to “0” after the operation is completed. In the repeat mode or repeat sweep mode, the A-D converter continues operating until this bit is cleared to “0” by software.

● When external trigger is selected

When the $\overline{\text{ADTRG}}$ pin level goes from “H” to “L” with this bit = “1,” a trigger occurs, causing the A-D converter to start operating. The A-D converter stops when this bit is cleared to “0.”

In the one-shot mode or single sweep mode, this bit remains set to “1” even after the operation is completed. In the repeat mode or repeat sweep mode, the A-D converter continues operating until this bit is cleared to “0” by software.

(4) A-D conversion frequency (ϕ_{AD}) select bit (bit 7)

As listed in Table 12.2.1, the conversion time of the A-D converter varies depending on the operating clock (ϕ_{AD}) selected by this bit.

Since the A-D converter’s comparator consists of capacity coupling amplifiers, keep that $\phi_{\text{AD}} \geq 250$ kHz during A-D conversion.

Table 12.2.1 Conversion time per one analog input pin (unit: μs)

A-D conversion frequency (ϕ_{AD}) select bit		0	1
ϕ_{AD}		$f_2/4$	$f_2/2$
Conversion time	$f(X_{\text{IN}}) = 8 \text{ MHz}$	57.0	28.5
	$f(X_{\text{IN}}) = 16 \text{ MHz}$	28.5	14.25
	$f(X_{\text{IN}}) = 25 \text{ MHz}$	18.24	9.12

12.2.2 A-D sweep pin select register

Figure 12.2.3 shows the structure of the A-D sweep pin select register.

Fig. 12.2.3 Structure of A-D control register 1

(1) A-D sweep pin select bits (bits 1 and 0)

These bits are used to select analog input pins in the single sweep mode or repeat sweep mode. In the single sweep mode and repeat sweep mode, pins which are not selected as analog input pins function as programmable I/O ports.

A-D CONVERTER

12.2 Block description

12.2.3 A-D register i (i = 0 to 7)

Figure 12.2.4 shows the structure of the A-D register i. When the A-D conversion is completed, the conversion result (contents of the successive approximation register) is stored into this register. Each A-D register i corresponds to an analog input pin (ANi).

Fig. 12.2.4 Structure of A-D register i

A-D CONVERTER

12.2 Block description

12.2.4 A-D conversion interrupt control register

Figure 12.2.5 shows the structure of the A-D conversion interrupt control register. For details about interrupts, refer to “CHAPTER 7. INTERRUPTS.”

Fig. 12.2.5 Structure of A-D conversion interrupt control register

(1) Interrupt priority level select bits (bits 2 to 0)

These bits select an A-D conversion interrupt's priority level. When using A-D conversion interrupts, select one of the priority levels (1 to 7). When an A-D conversion interrupt request occurs, its priority level is compared with the processor interrupt priority level (IPL). The requested interrupt is enabled only when its priority level is higher than the IPL. (However, this applies when the interrupt disable flag (I) = "0.")

To disable A-D conversion interrupts, set these bits to "0002" (level 0).

(2) Interrupt request bit (bit 3)

This bit is set to "1" when an A-D conversion interrupt request occurs. This bit is automatically cleared to "0" when the A-D conversion interrupt request is accepted. This bit can be set to "1" or cleared to "0" by software.

12.2.5 Port P7 direction register

Input pins of the A-D converter are multiplexed with port P7. When using these pins as A-D converter's input pins, set the corresponding bits of the port P7 direction register to "0" to set these port pins for the input mode. Figure 12.2.6 shows the relationship between the port P7 direction register and A-D converter's input pins.

Fig. 12.2.6 Relationship between port P7 direction register and A-D converter's input pins

A-D CONVERTER

12.3 A-D conversion method

12.3 A-D conversion method

The A-D converter compares the comparison voltage (V_{ref}), which is internally generated according to the contents of the successive approximation register, with the analog input voltage (V_{IN}), which is input from the analog input pin (AN_i). By reflecting the comparison result on the successive approximation register, V_{IN} is converted into a digital value. When a trigger is generated, the A-D converter performs the following processing:

① **Determining bit 7 of the successive approximation register**

The A-D converter compares V_{ref} with V_{IN} . At this time, the contents of the successive approximation register is "1000000₂" (initial value).

Bit 7 of the successive approximation register changes according to the comparison result as follows:

When $V_{ref} < V_{IN}$, bit 7 = "1"

When $V_{ref} > V_{IN}$, bit 7 = "0"

② **Determining bit 6 of the successive approximation register**

After setting bit 6 of the successive approximation register to "1," the A-D converter compares V_{ref} with V_{IN} . Bit 6 changes according to the comparison result as follows:

When $V_{ref} < V_{IN}$, bit 6 = "1"

When $V_{ref} > V_{IN}$, bit 6 = "0"

③ **Determining bits 5 to 0 of the successive approximation register**

Operations in ② are performed for bits 5 to 0.

When bit 0 is determined, the contents (conversion result) of the successive approximation register is transferred to the A-D register i.

The comparison voltage (V_{ref}) is generated according to the latest contents of the successive approximation register. Table 12.3.1 lists the relationship between the successive approximation register's contents and V_{ref} . Table 12.3.2 lists changes of the successive approximation register and V_{ref} during the A-D conversion. Figure 12.3.1 shows the ideal A-D conversion characteristics.

Fig. 12.3.1 Ideal A-D conversion characteristics

A-D CONVERTER

12.4 Absolute accuracy and differential non-linearity error

12.4 Absolute accuracy and differential non-linearity error

The A-D converter's accuracy is described below. Refer to section "Appendix 12.3 A-D converter standard characteristics," also.

12.4.1 Absolute accuracy

The absolute accuracy is the difference expressed in the LSB between the actual A-D conversion result and the output code of an A-D converter with ideal characteristics. The analog input voltage when measuring the accuracy is assumed to be the mid point of the input voltage width that outputs the same output code from an A-D converter with ideal characteristics. For example, when $V_{REF} = 5.12\text{ V}$, 1 LSB width is 20 mV, and 0 mV, 20 mV, 40 mV, 60 mV, 80 mV, ... are selected as the analog input voltages.

The absolute accuracy = $\pm 3\text{ LSB}$ indicates that when the analog input voltage is 100 mV, the output code expected from an ideal A-D conversion characteristics is "005₁₆," however the actual A-D conversion result is between "002₁₆" to "008₁₆."

The absolute accuracy includes the zero error and the full-scale error.

The absolute accuracy is degraded when V_{REF} is lowered. Any of the output codes for analog input voltages from V_{REF} to AV_{CC} is "FF₁₆."

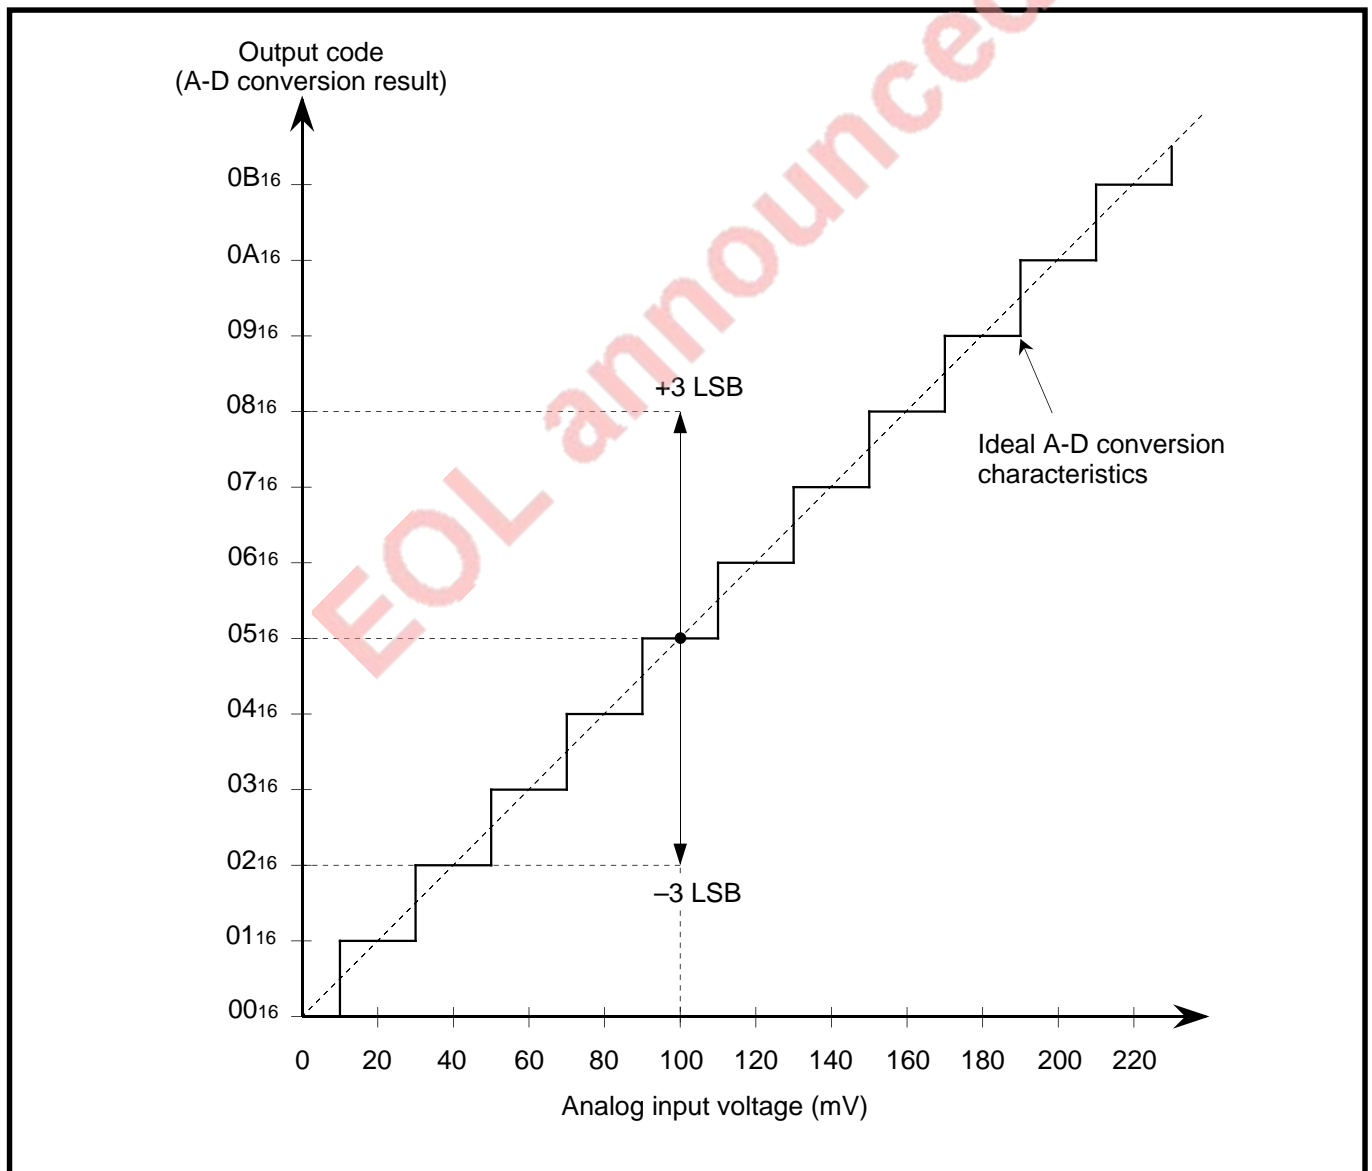

Fig. 12.4.1 Absolute accuracy of A-D converter

A-D CONVERTER

12.4 Absolute accuracy and differential non-linearity error

12.4.2 Differential non-linearity error

The differential non-linearity error indicates the difference between the 1 LSB step width (the ideal analog input voltage width while the same output code is expected to output) of an A-D converter with ideal characteristics and the actual measured step width (the actual analog input voltage width while the same output code is output). For example, when $V_{REF} = 5.12$ V, the 1 LSB width of an A-D converter with ideal characteristics is 20 mV, however when the differential non-linearity error is ± 1 LSB, the actual measured 1 LSB width is 0 to 40 mV.

Fig. 12.4.2 Differential non-linearity error

A-D CONVERTER

12.5 One-shot mode

12.5 One-shot mode

In the one-shot mode, the operation for the input voltage from the one selected analog input pin is performed once, and the A-D conversion interrupt request occurs when the operation is completed.

12.5.1 Settings for one-shot mode

Figure 12.5.1 shows an initial setting example for registers relevant to the one-shot mode.

When using an interrupt, it is necessary to set the relevant registers to enable the interrupt. Refer to “CHAPTER 7. INTERRUPTS” for more descriptions.

EOL announced

Fig. 12.5.1 Initial setting example for registers relevant to one-shot mode

A-D CONVERTER

12.5 One-shot mode

12.5.2 One-shot mode operation description

(1) When an internal trigger is selected

- ① The A-D converter starts operation when the A-D conversion start bit is set to “1.”
- ② The A-D conversion is completed after 57 cycles of ϕ_{AD} . Then, the contents of the successive approximation register (conversion result) are transferred to the A-D register i.
- ③ At the same time as step ②, the A-D conversion interrupt request bit is set to “1.”
- ④ The A-D conversion start bit is cleared to “0” and the A-D converter stops operation.

(2) When an external trigger is selected

- ① The A-D converter starts operation when the input level to the $\overline{AD_{TRG}}$ pin changes from “H” to “L” while the A-D conversion start bit is “1.”
- ② The A-D conversion is completed after 57 cycles of ϕ_{AD} . Then, the contents of the successive approximation register (conversion result) are transferred to the A-D register i.
- ③ At the same time as step ②, the A-D conversion interrupt request bit is set to “1.”
- ④ The A-D conversion stops.

The A-D conversion start bit remains set to “1” after the operation is completed. Accordingly, the operation of the A-D converter can be performed again from step ① when the level of the $\overline{AD_{TRG}}$ pin changes from “H” to “L.”

When the level of the $\overline{AD_{TRG}}$ pin changes from “H” to “L” during operation, the operation at that point is cancelled and is restarted from step ①.

Figure 12.5.2 shows the conversion operation in the one-shot mode.

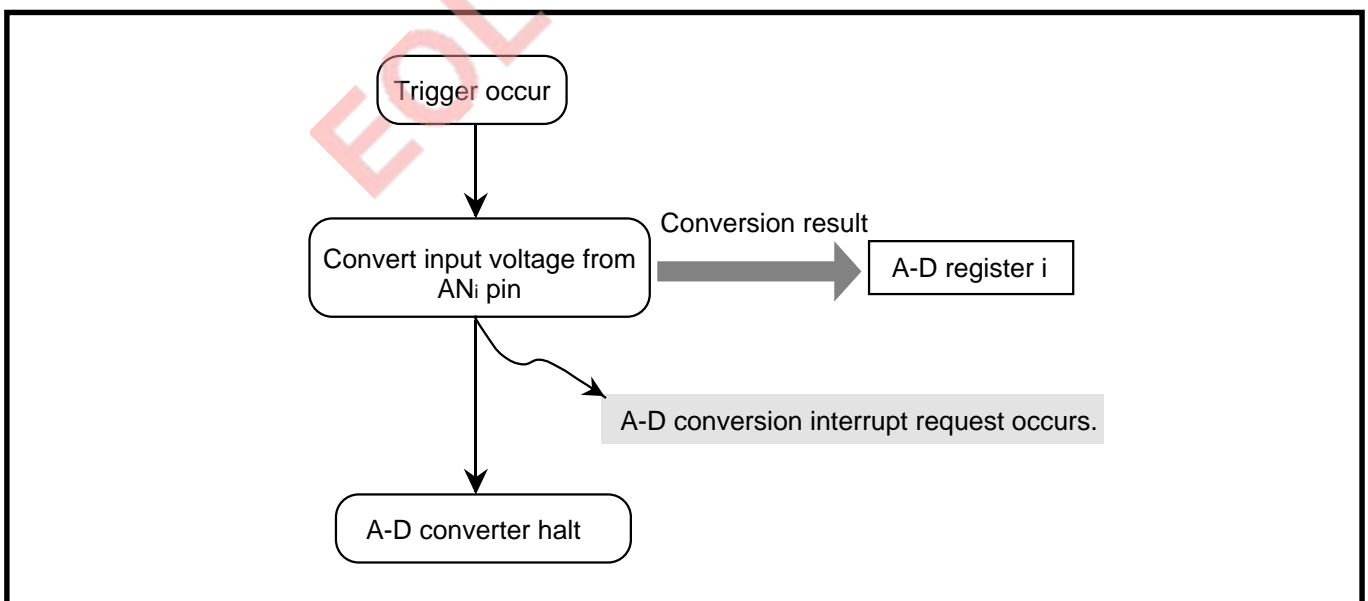

Fig. 12.5.2 Conversion operation in one-shot mode

12.6 Repeat mode

In the repeat mode, the operation for the input voltage from the one selected analog input pin is performed repeatedly.

In this mode, no A-D conversion interrupt request occurs. Additionally, the A-D conversion start bit (bit 6 at address 1E₁₆) remains set to "1" until it is cleared to "0" by software, and the operation is performed repeatedly while the A-D conversion start bit is "1."

A-D CONVERTER

12.9 Precautions for A-D converter

12.9 Precautions for A-D converter

1. Writing to the following must be performed before a trigger occurs (while the A-D converter halts).
 - Each bit (except bit 6) of the A-D control register
 - Each bit of the A-D sweep pin select register
2. When an external trigger is selected, the $\overline{AN_7/AD_{TRG}}$ pin is disconnected from the comparator. Therefore, this pin cannot be used as an analog input pin.
When the $\overline{AN_7}$ pin is selected as an analog input pin while an external trigger is selected, the A-D converter operates, however, an undefined value is stored into the A-D register 7.
3. Refer to “**Appendix. 8 Countermeasure against noise**” when using the A-D converter.

DMA CONTROLLER

13.1 Overview

13.1 Overview

The DMA controller (hereafter called DMAC) transfers data using the bus and bypassing the CPU. DMAC of the M37721 provides four independent channels of DMA0–DMA3, which have the same function each. In this chapter, the source and destination of each DMA transfer are represented as follows.

- Memory
A device which needs its own address to be specified
Examples: Internal RAM and SFRs, external memory, and memory-mapped I/Os
- I/O
A device which does not need its own address to be specified
Example: External I/O devices

13.1.1 Performance overview

Table 13.1.1 lists the performance overview.

Table 13.1.1 DMAC performance overview

Item	Performance specifications
Number of channels	4 channels
Transfer space	16 Mbytes (between arbitrary spaces)
Number of transfer bytes	Maximum of 16 Mbytes
DMA request source	Internal 14 sources and External 1 source
Channel priority	Fixed or Rotating
Transfer rate	Maximum of 12.5 Mbytes/sec (at $f(X_{IN}) = 25$ MHz, 1-bus cycle transfer) Maximum of 6.25 Mbytes/sec (at $f(X_{IN}) = 25$ MHz, 2-bus cycle transfer)
Data transfer method	1-bus cycle or 2-bus cycle transfer
Transfer unit	8 or 16 bits
Address direction of transfer	Fixed, Forward, or Backward (Directions of source and destination are independently selectable.)
Transfer mode	Burst transfer or Cycle-steal transfer mode
Continuous transfer mode	Single transfer, Repeat transfer, Array chain transfer, or Link array chain transfer mode

13.1.2 Bus use priority levels

The bus use priority levels are fixed by hardware as follows:

DRAMC > Hold function > DMAC > CPU
(DRAM refresh)

Because DMAC has the third priority, it actually operates as follows:

- **When DRAM refresh request or Hold request is generated during DMA transfer**
After the transfer of one transfer unit (8-bit or 16-bit data), which is being performed at that time, is complete, DMAC relinquishes the bus to a DRAM refresh or a Hold function.
When DMAC regains the right to use bus after the DRAM refresh ends or the Hold state is removed, DMA transfer is restarted at the following address.
- **When DMA request is generated during DRAM refresh or in Hold state**
DMAC gains the right to use bus after the DRAM refresh ends or the Hold state is removed.
- **When DMA request is generated while CPU uses bus**
Upon end of the bus cycle, DMAC gains the right to use bus if any DRAM refresh request or Hold request is not generated at that time.
If a DRAM refresh request or a Hold request is generated when the bus cycle ends, DMAC gains the right to use bus after the DRAM refresh ends or the Hold state is removed.

For details, refer to section “13.2.1 Bus access control circuit” and bus request sampling signals in timing diagrams.

13.1.3 Modes

DMAC has the following transfer methods and modes. Because these methods and modes are independent each other, any combination between them is selectable.

(1) Data transfer method

■ 2-bus cycle transfer

This is a method used to transfer data between memories. A DMA transfer consumes 2 cycles: a read and a write cycle of data.

For details, refer to section “13.4.1 2-bus cycle transfer.”

■ 1-bus cycle transfer

This is a method used to transfer data between a memory and an I/O. A read and write of data is carried out at the same time (in 1-bus cycle), so that high-speed transfer can be accomplished.

For details, refer to section “13.4.2 1-bus cycle transfer.”

(2) Transfer unit

■ 8-bit transfer

A minimum unit of DMA transfer is 8 bits; that is, an 8-bit data is transferred for one DMA request in the cycle-steal transfer mode.

In the burst transfer mode, if a DRAM refresh request or a Hold request is generated during DMA transfer, or if \overline{TC} input is driven from “H” to “L” to force DMA transfer into termination, DMAC relinquishes the bus after completion of 8-bit data transfer which is being performed at that time.

■ 16-bit transfer

A minimum unit of DMA transfer is 16 bits; that is, a 16-bit data is transferred for one DMA request in the cycle-steal transfer mode.

In the burst transfer mode, if a DRAM refresh request or a Hold request is generated during DMA transfer, or if \overline{TC} input is driven from “H” to “L” to force DMA transfer into termination, DMAC relinquishes the bus after completion of 16-bit data transfer which is being performed at that time.

DMA CONTROLLER

13.1 Overview

(3) Transfer modes

■ Burst transfer mode

When once a DMA request is accepted in this mode, an entire batch of data is transferred. Neither is the right to use bus returned to the CPU, nor the DMA request of the channel with the higher priority is accepted until the transfer is complete. However, if an external source ($\overline{\text{DMAREQ}}_i$) is selected as a DMA request source with the level sense selected, DMA transfer is performed when the $\overline{\text{DMAREQ}}_i$ pin's input level is "L," and the right to use bus is returned to the CPU when the $\overline{\text{DMAREQ}}_i$ pin's input level is "H." Even in this case, any DMA request of the other channels is not accepted until the entire batch of data has been transferred.

For details, refer to section "13.4.3 Burst transfer mode."

■ Cycle-steal transfer mode

For each DMA request, 1 transfer unit of data is transferred. (Hereafter, transferring 1-transfer-unit data, which is 8-bit or 16-bit data in the M37721, is called "1-unit transfer.")

When 1-unit transfer is complete and another DMA request (including that of other channels) is not generated, the DMAC relinquishes the right to use bus to the CPU.

In the cycle-steal transfer mode, all of the DMA request sources are available.

For details, refer to section "13.4.4 Cycle-steal transfer mode."

Figure 13.1.1 shows the outline of the DMA transfer modes.

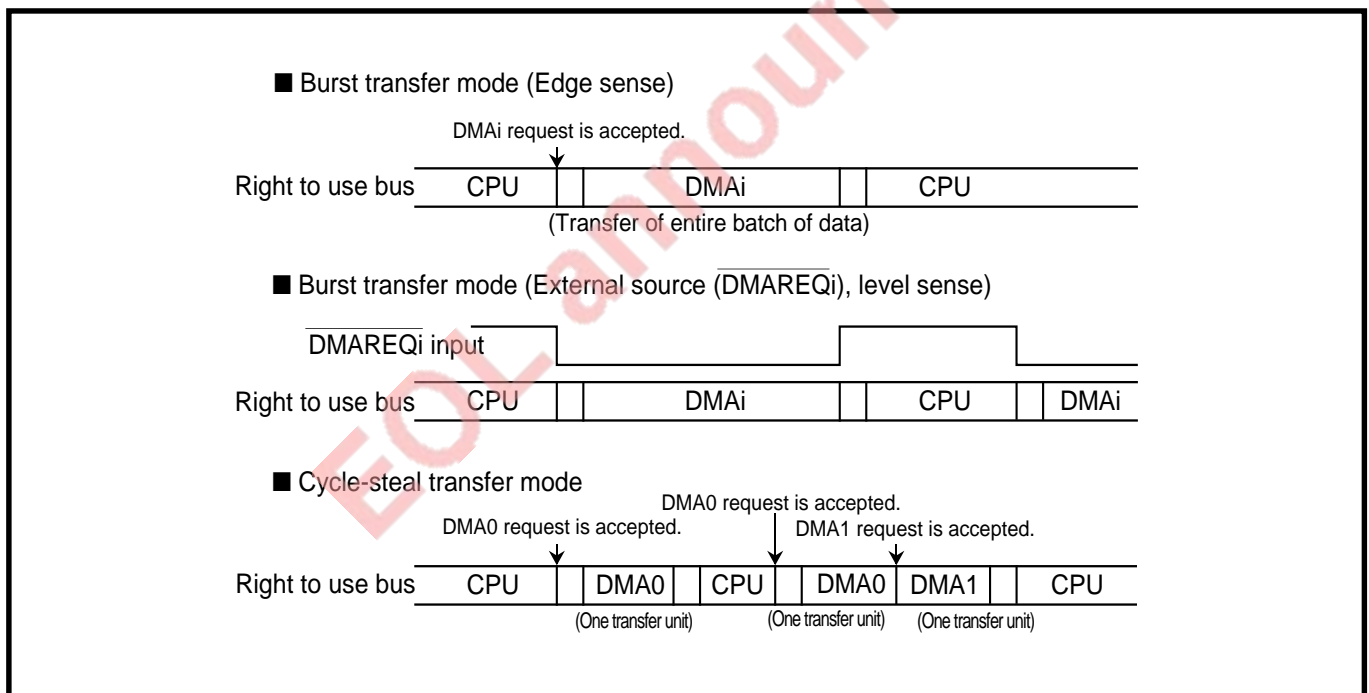

Fig. 13.1.1 Outline of DMA transfer modes

(4) Continuous transfer mode

■ Single transfer mode

1 block of data is transferred once.

For details, refer to section “13.5 Single transfer mode.”

■ Repeat transfer mode

1 block of data is transferred repeatedly.

For details, refer to section “13.6 Repeat transfer mode.”

■ Array chain transfer mode

Several blocks of data are transferred.

The transfer parameters (transfer source and destination addresses, the number of transfer bytes) of each block must be located on the memory in series.

For details, refer to section “13.7 Array chain transfer mode.”

■ Link array chain transfer mode

Several blocks of data are transferred.

Transfer parameters for each block can be located on the memory in separate, in a unit of 1-block's parameters.

For details, refer to section “13.8 Link array chain transfer mode.”

DMA CONTROLLER

13.2 Block description

13.2.1 Bus access control circuit

In the M37721, the bus is used by DRAMC, Hold function, DMAC, and CPU.

When each request of DRAM refresh, Hold, and DMA is generated, each of DRAMC, Hold function, and DMAC issues its bus request to the bus access control circuit in DMAC. (Refer to “Figure 13.2.2.”)

Table 13.2.1 lists the bus request generating sources.

Table 13.2.1 Bus request generating sources

Bus request	Bus request generating source
BUS REQUEST (DRAMC)	DRAM refresh request (Generated by an underflow of the refresh timer.)
BUS REQUEST (Hold)	Hold request (Generated by “L”-level input to the $\overline{\text{HOLD}}$ pin.)
BUS REQUEST (DMAC)	DMA request (Generated by a DMA request source.)

The bus access control circuit relinquishes the right to use bus to the function with the highest priority among functions, which issue bus requests when the BUS REQUEST signal is sampled. This is the bus request acceptance. If any bus request is not generated at bus request sampling, the CPU gains the right to use bus.

The bus use priority levels are fixed by hardware, and the bus status is reported by status signal outputs ST0 and ST1. Table 13.2.2 lists the relationship between the bus use priority level, bus status, and status signals.

Table 13.2.2 Relationship between bus use priority level, bus status, and status signals

Bus use priority level	Bus status	Status signals	
		ST1	ST0
1 (Highest)	DRAM refresh	0	0
2	Hold	0	1
3	DMAC	1	0
4 (Lowest)	CPU (Including the term while the CPU does not use the bus; for example, the term when the CPU is calculating and does not use the bus)	1	1

DMA CONTROLLER

13.2 Block description

The BUS REQUEST signal is sampled at a break in bus use. Table 13.2.3 and Figure 13.2.3 shows the timings of bus request sampling. Also, bus request sampling signals are shown in them.

Table 13.2.3 Bus request sampling timing

Bus user		Bus request sampling timing	
DRAM refresh		After completion of a DRAM refresh cycle	
Hold		Every 1 cycle of ϕ	
DMAC	S/R (Note 1)	All except the following	After completion of 1-unit transfer
		At the end of each block	After 1-unit transfer and terminate-processing (3 cycles of ϕ) etc. are performed sequentially
	Array/ Link (Note 1)	All except the following	After completion of 1-unit transfer
		At the end of each block (except the last block)	<p>■ During transfer in burst transfer mode After the last 1-unit transfer of 1 block, the subsequent 3 cycles of ϕ, and a read of the first 2 bytes in the array state of the next block are performed sequentially</p> <p>■ During transfer in cycle-steal transfer mode After the last 1-unit transfer of 1 block and the subsequent 3 cycles of ϕ are performed sequentially</p>
		At the end of the last block	After 1-unit transfer and terminate-processing (3 cycles of ϕ) are performed sequentially
At an array state	After a read of 2 bytes of a transfer parameter		
CPU	When an instruction is fetched into queue buffer		After completion of 1 bus cycle
	At a read from or a write into memory		After completion of 1 bus cycle, or after completion of the second bus cycle if a 16-bit data is accessed in a unit of 8 bits (Note 2) .
	While CPU does not use bus		Every 1 cycle of ϕ

Notes 1: S = Single transfer mode, R = Repeat transfer mode, Array = Array chain transfer mode, Link = Link array chain transfer mode

2: This applies when the data bus width is 8 bits or when memory is accessed starting at an odd address.

If a DRAM refresh request or a Hold request is generated during a data transfer in the burst transfer mode, the request is accepted at the above-mentioned bus request sampling. Another DMA request (including that of other channels) cannot be accepted until the DMA transfer which is in progress normally terminates or is forced into termination.

If a DRAM refresh request, a Hold request or another DMA request (including that of other channels) is generated during a data transfer in the cycle-steal transfer mode, the bus request with the highest priority is accepted at the above-mentioned bus request sampling. (If only several DMA requests are generated, the request of the channel whose priority is highest is accepted.)

If any bus request is not generated at the above-mentioned bus sampling, the right to use bus is relinquished to the CPU.

Note that no DMA request is accepted in array states.

Fig. 13.2.3 Timing of bus request sampling

DMA CONTROLLER

13.2 Block description

13.2.2 DMAC control register L

Figure 13.2.4 shows the structure of DMAC control register L. Bit 0 is described in section “13.3.3 Channel priority levels,” and bits 4–7 are also in section “13.3.2 DMA requests.”

(1) \overline{TC} pin validity bit (Bit 1)

When this bit is set to “1,” port P10₃ functions as the \overline{TC} pin. The \overline{TC} pin is of an N-channel open-drain type and provides the following functions:

- **Terminal count signal output**

When the transfer of an entire batch of data is normally terminated, the pin outputs “L” for 1 cycle of ϕ . (Refer to section “13.3.5 (1) Normal termination.”)

- **Forced termination signal input**

When the \overline{TC} pin’s input level goes from “H” to “L” during DMA transfer, this DMA transfer is forced into termination. (Refer to section “13.3.5 (2) Forced termination.”)

Fig. 13.2.4 Structure of DMAC control register L

DMA CONTROLLER

13.2 Block description

13.2.3 DMAC control register H

Figure 13.2.5 shows the structure of DMAC control register H. Each of bits 0–3 is a software DMA_i (i = 0 to 3) request bit, which corresponds to each channel. When a software DMA source is selected as a DMA request source, each of these bits is valid. (Refer to “13.3.2 DMA requests.”) Bits 4–7 are described in section “13.3.1 DMA enabling.”

Fig. 13.2.5 Structure of DMAC control register H

DMA CONTROLLER

13.2 Block description

13.2.4 Source address register i (SARi)

Source address register i (hereafter called SARi) is a 24-bit register with a latch.

SARi indicates the transfer source address of the data to be transferred next.

The SARi latch has the following functions:

- Maintains the value written to the address of SARi (in the single transfer and repeat transfer modes).
- Indicates the start address of the transfer parameter memory of the next block (in the array chain transfer and link array chain transfer modes).

When a value is written into the address of SARi, the same value is written into SARi and the SARi latch.

When writing a value to the address of SARi, all 24 bits must be written.

The contents of SARi can be read by reading the address of SARi; however, the value of the SARi latch cannot be read. (Refer to “**Tables 13.2.4 and 13.2.5.**”)

13.2.5 Destination address register i (DARi)

Destination address register i (hereafter called DARi) is a 24-bit register with a latch.

DARi indicates the transfer destination address of the data to be transferred next.

The DARi latch maintains the value written to the address of DARi.

When a value is written into the address of DARi, the same value is written into DARi and the DARi latch.

When writing a value to the address of DARi, all 24 bits must be written.

The contents of DARi can be read by reading the address of DARi; however, the value of the DARi latch cannot be read. (Refer to “**Tables 13.2.4 and 13.2.5.**”)

13.2.6 Transfer counter register i (TCRi)

Transfer counter register i (hereafter called TCRi) is a 24-bit register with a latch.

TCRi indicates the number of remaining bytes of the block under transfer.

The TCRi latch has the following functions:

- Maintains the value written to the address of TCRi (in the single transfer and repeat transfer modes).
- Indicates the number of remaining blocks (in the array chain transfer mode).

When a value is written into the address of TCRi, the same value is written into TCRi and the TCRi latch.

When writing a value to the address of TCRi, all 24 bits must be written.

The contents of TCRi can be read by reading the address of TCRi; however, the value of the TCRi latch cannot be read. (Refer to “**Tables 13.2.4 and 13.2.5.**”)

Table 13.2.4 Addresses of SARi, DARi, and TCRi

Channel	Source address register i (SARi)	Destination address register i (DARi)	Transfer counter register i (TCRi)
0	1FC2 ₁₆ –1FC0 ₁₆	1FC6 ₁₆ –1FC4 ₁₆	1FCA ₁₆ –1FC8 ₁₆
1	1FD2 ₁₆ –1FD0 ₁₆	1FD6 ₁₆ –1FD4 ₁₆	1FDA ₁₆ –1FD8 ₁₆
2	1FE2 ₁₆ –1FE0 ₁₆	1FE6 ₁₆ –1FE4 ₁₆	1FEA ₁₆ –1FE8 ₁₆
3	1FF2 ₁₆ –1FF0 ₁₆	1FF6 ₁₆ –1FF4 ₁₆	1FFA ₁₆ –1FF8 ₁₆

DMA CONTROLLER

13.2 Block description

Table 13.2.5 Functions of SARi, DARi, and TCRi

Register		Mode	Single transfer mode	Repeat transfer mode	Array chain transfer mode	Link array chain transfer mode
SARi	SARi		Indicates the transfer source address of the data to be transferred next.			
	SARi latch		Maintains the transfer start address of the source.		Indicates the start address of the transfer parameter memory of the next block.	
DARi	DARi		Indicates the transfer destination address of the data next to be transferred			
	DARi latch		Maintains the transfer start address of the destination.		(Not used)	(Not used)
TCRi	TCRi		Indicates the number of remaining bytes of the block under transfer.			
	TCRi latch		Maintains the byte number of the transfer data.		Indicates the number of remaining blocks.	(Not used) (Note)

Note: Any value other than 0 (000001₁₆–FFFFFF₁₆) must be written before DAM transfer.

13.2.7 Incrementer/Decrementer

The incrementer/decrementer is a 24-bit register. After every 1-unit transfer, that increments (adds) or decrements (subtract) the contents of SARi and DARi.

Table 13.2.6 lists the increment/decrement values.

Table 13.2.6 Increment/Decrement values

Transfer unit	Address directions	
	Forward	Backward
8 bits	+ 1	– 1
16 bits	+ 2	– 2

13.2.8 Decrementer

The decrementer is a 24-bit register. After every 1-unit transfer, that decrements the contents of TCRi by 1 when the transfer unit is 8 bits, and by 2 when 16 bits.

In the array chain transfer mode, every time a transfer parameter is read, the contents of the TCRi latch are also decremented by 1.

13.2.9 DMA latch

The DMA latch is a 16-bit latch.

In 2-bus cycle transfer mode, the DMA latch maintains the value read from the transfer source memory with a read cycle until this value is written into the transfer destination memory.

In 1-bus cycle transfer mode, the DMA latch is used to copy data. For copy, refer to section “13.4.2 1-bus cycle transfer.”

DMA CONTROLLER

13.2 Block description

13.2.10 DMAi mode register L

Figure 13.2.6 shows the structure of DMAi mode register L. For bit 0, refer to section “13.1.3 (2) Transfer unit.” For bit 1, refer to section “13.4.1 2-bus cycle transfer” and section “13.4.2 1-bus cycle transfer”; for bit 2, refer to section “13.4.3 Burst transfer mode” and section “13.4.4 Cycle-steal transfer mode.”

(1) Transfer source address direction select bits (bits 4 and 5) and Transfer destination address direction select bits (bits 6 and 7)

Address direction means an order of accessing memory in DMA transfer and is defined as follows:

- Fixed direction: an address does not move.
- Forward direction: an address moves upward from the specified start address.
- Backward direction: an address moves downward from the specified start address.

For details, refer to section “13.4.1 (3) Address directions in 2-bus cycle transfer” and section “13.4.2 (3) Address directions in 1-bus cycle transfer.”

Fig. 13.2.6 Structure of DMAi mode register L

13.2.11 DMAi mode register H

Figure 13.2.7 shows the structure of DMAi mode register H. Bits 0 and 1 are used in 1-bus cycle transfer. For details, refer to section “13.4.2 1-bus cycle transfer.” Bits 6 and 7 are the bits for selecting the continuous transfer mode. For details, refer to section “13.5 Single transfer mode” through section “13.8 Link array chain transfer mode.”

(1) Transfer source wait bit and Transfer destination wait bit (bits 4 and 5)

When each of these bits is set to “1,” 1-bus cycle in a DMA transfer consumes 3 cycles of ϕ , and when cleared to “0,” 2 cycles of ϕ .

These bits are valid for the internal and external areas. In the DRAM area, however, 1-bus cycle consumes 3 cycles of ϕ regardless of the states of these bits. (Refer to “CHAPTER 14. DRAM CONTROLLER.”)

The wait bit (bit 2 at address 5E₁₆) is invalid in DMA transfer. However, Ready function is still valid in DMA transfer.

Fig. 13.2.7 Structure of DMAi mode register H

DMA CONTROLLER

13.2 Block description

13.2.12 DMAi control register

Figure 13.2.8 shows the structure of the DMAi control register. For bits 0–4, refer to section “13.3.2 (1) DMA request sources.”

(1) DMAACKi validity bit (bit 5)

When this bit is set to “1,” the corresponding pin of port P9 serves as the DMAACKi pin and outputs “L” during a DMA transfer. For details, refer to each timing diagram of section “13.5 Single transfer mode” through section “13.8 Link array chain transfer mode.”

Fig. 13.2.8 Structure of DMAi control register

13.2.13 DMAi interrupt control register

Figure 13.2.9 shows the structure of the DMAi interrupt control register. For details about interrupts, refer to “CHAPTER 7. INTERRUPTS.”

Fig. 13.2.9 Structure of DMAi interrupt control register

(1) Interrupt priority level select bits (bits 2 to 0)

These bits select a DMAi interrupt's priority level. When using DMAi interrupts, select one of the priority levels (1 to 7). When a DMAi interrupt request occurs, its priority level is compared with the processor interrupt priority level (IPL). The requested interrupt is enabled only when its priority level is higher than the IPL. (However, this applies when the interrupt disable flag (I) = "0.")

To disable DMAi interrupts, set these bits to "000₂" (level 0).

(2) Interrupt request bit (bit 3)

This bit is set to "1" when a DMAi interrupt request occurs after the DMA transfer is complete. This bit is automatically cleared to "0" when the DMAi interrupt request is accepted. This bit can be set to "1" or cleared to "0" by software.

DMA CONTROLLER

13.2 Block description

13.2.14 Port P9 direction register

I/O pins of DMAi are multiplexed with port P9. When using these pins as the \overline{DMAREQ}_i input pins, set the corresponding bits of the port P9 direction register to “0” to set these port pins for the input mode. When using these pins as the \overline{DMAACK}_i output pins, these pins are forcibly set to the \overline{DMAACK}_i output pins regardless of the direction register’s contents. Figure 13.2.10 shows the relationship between the port P9 direction register and DMAi’s I/O pins.

Fig. 13.2.10 Relationship between port P9 direction register and DMAi’s I/O pins

[Precautions for DMAC]

Do not access the registers relevant to DMAC by using DMA transfers; the address of the accessing register collides with that of the accessed one on the DMAC internal bus.

13.3 Control

The conditions for performing DMA transfer of DMA_i (i = 0–3) are as follows:

- Neither a DRAM refresh request nor a Hold request is generated.
- A request of the channel with a higher priority than that of DMA_i is not generated; or the request is disabled though it has been generated.
- DMA_i is enabled (DMA_i enable bit = “1”).
- A DMA_i request is generated (DMA_i request bit = “1”).

The control method for each channel is described below.

13.3.1 DMA enabling

Each of DMA channels 0–3 has a DMA_i enable bit (bits 4–7 at address 69₁₆). Table 13.3.1 lists the conditions for changing each DMA_i enable bit.

Table 13.3.1 Conditions for changing DMA_i enable bit

DMA _i enable bit	Conditions for bit change
Is set to “1.”	A write of “1” to the DMA _i enable bit
Is cleared to “0.”	<ul style="list-style-type: none"> • A write of “0” to the DMA_i enable bit • Transfer of an entire batch of data is complete (normal termination). • A change of \overline{TC} input level from “H” to “L” during a DMA transfer of DMA_i (Note) (Forced termination, when \overline{TC} pin is valid.)

Note: In the burst transfer mode (level sense), however, the term from the DMA transfer start until the transfer completion of an entire batch of data is applied. (It is also valid while the CPU has the right to use bus.)

DMA CONTROLLER

13.3 Control

13.3.2 DMA requests

(1) DMA request sources

DMA request sources are specified by the DMA request source select bits and the edge sense/level sense select bit. (Refer to “**Figure 13.2.8.**”)

Table 13.3.2 lists the conditions for generating a DMA request.

Table 13.3.2 Conditions for generating DMA request

DMA request sources		Condition for generating DMA request
External source DMAREQ _i	Level sense	“L”-level input to the $\overline{\text{DMAREQ}}_i$ pin (only in the burst transfer mode)
	Edge sense	Change of the $\overline{\text{DMAREQ}}_i$ input pin’s level from “H” to “L”
Software DMA _i request		A write of “1” to the software DMA _i request bit (each of bits 0–3 at address 69 ₁₆ ; refer to “ Figure 13.2.5. ”)
Timers A0–A4, Timers B0–B2, UART0, UART1, A-D converter		When the interrupt request bit of each peripheral is set to “1” by the activity of peripherals (If “1” is written to any of these interrupt request bits by software, the DMA _i request bit does not change. Also, whatever value within 0–7 an interrupt priority level takes, this does not affect DMA requests.)

(2) Change of DMA_i request bit

A read of the DMA_i request bits (each of bits 4–7 at address 68₁₆) indicates whether the corresponding channel (0–3) is generating its DMA request or not. The DMA_i request bit changes synchronized with the falling edge of ϕ_1 . Table 13.3.3 lists the conditions for changing the DMA_i request bit.

For the timing of changing the DMA_i request bit, refer to “**Figures 13.3.2 and 13.3.3.**”

Table 13.3.3 Conditions for changing DMA_i request bit

DMA _i request bit	Mode	Burst transfer mode		Cycle-steal transfer mode
		Edge sense	Level sense	
Is set to “1.” (Note)		Generation of DMA _i request (Refer to “ Table 13.3.2. ”)	Generation of DMA _i request (“L”-level input to the $\overline{\text{DMAREQ}}_i$ pin)	Generation of DMA _i request (Refer to “ Table 13.3.2. ”)
Is cleared to “0.”		<ul style="list-style-type: none"> Normal termination Change of the $\overline{\text{TC}}$ pin’s input level from “H” to “L” during DMA transfer (when the $\overline{\text{TC}}$ pin is valid) 	<ul style="list-style-type: none"> “H”-level input to the $\overline{\text{DMAREQ}}_i$ pin Change of the $\overline{\text{TC}}$ pin’s input level from “H” to “L” (when the $\overline{\text{TC}}$ pin is valid) A write of “0” to the DMA_i request bit A write of “0” to the DMA_i enable bit 	<ul style="list-style-type: none"> Start of 1-unit transfer Change of the $\overline{\text{TC}}$ pin’s input level from “H” to “L” during DMA transfer (when the $\overline{\text{TC}}$ pin is valid) A write of “0” to the DMA_i request bit A write of “0” to the DMA_i enable bit

Note: While the DMA_i enable bit is “0,” the DMA_i request bit is not set to “1” even if a DMA request is generated. When the DMA_i enable bit is cleared to “0,” also the DMA_i request bit is cleared to “0.” However, the DMA request generated while the DMA_i enable bit = “0” is maintained; and when the DMA_i enable bit is set to “1,” the DMA_i request bit is also set to “1,” except for the burst transfer mode (level sense).

13.3.3 Channel priority levels

When the DMA enable bits of several channels are “1” and their DMA request bits are set to “1,” the request of the channel with the highest priority is accepted first.

The fixed or rotating channel priority can be selected by the priority select bit (bit 0 at address 68₁₆). The priority levels themselves cannot be specified arbitrary.

The channel priority levels are determined after the DMA requests are determined.

(1) Fixed priority

The fixed priority is selected when the priority select bit (bit 0 at address 68₁₆) = “0.”

In the fixed priority, the channel priority levels are as follows:

channel 0 > channel 1 > channel 2 > channel 3.

(2) Rotating priority

The rotating priority is selected when the priority select bit = “1.”

After reset, the priority levels are the same descending order as in the fixed priority:

channel 0 > channel 1 > channel 2 > channel 3.

Then, after every normal termination of a DMA transfer, the priority levels rotate in such a way that the lowest priority is given to the channel having been performed.

When DMA transfer is forced into termination, the channel priority levels does not rotate.

Figure 13.3.1 shows an example of determining the channel priority levels.

EOL announced

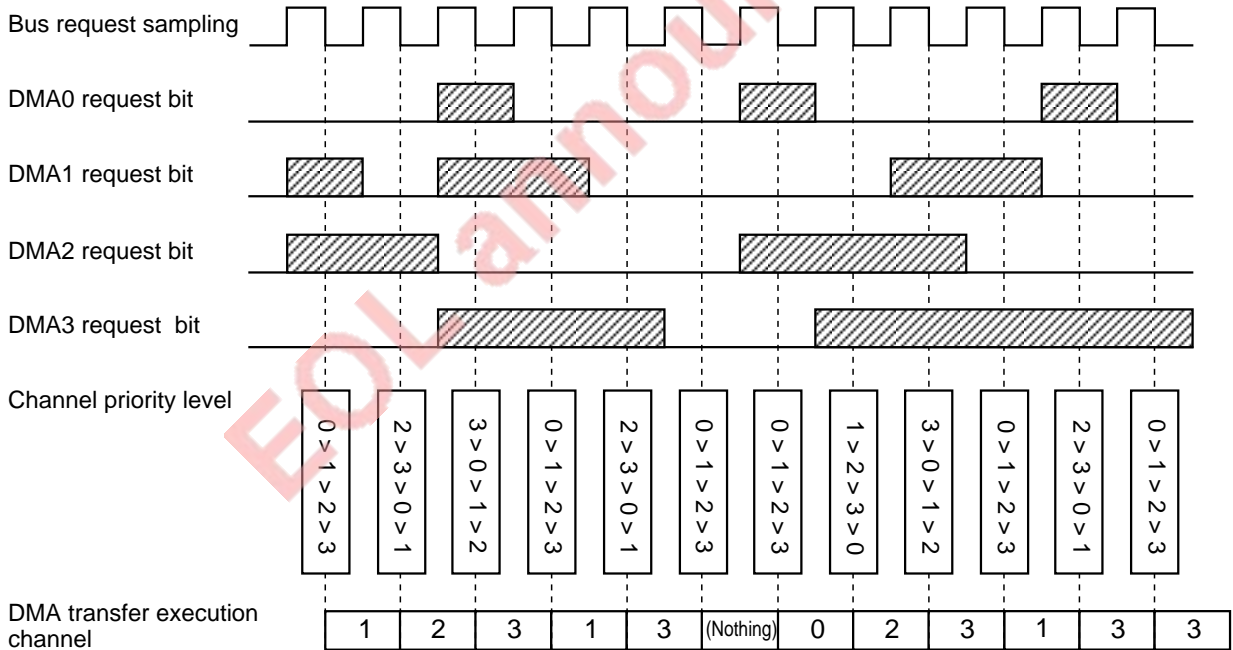

DMA CONTROLLER

13.3 Control

● Priority level: Fixed priority

● Priority level: Rotating priority

The above timing diagram applies on the following conditions:

- No DRAM refresh request, no Hold request
- All of DMA_i enable bits are "1."

Fig. 13.3.1 Example of determining channel priority levels

13.3.4 Processing from DMA request until DMA transfer execution

DMA requests are sampled at every falling edge of ϕ_1 ; when requested, the DMAi request bit is set to “1.” Then, the channel priority levels and bus use priority levels are determined, and BUS REQUEST (DMAC) goes “1” if any DRAM refresh request or Hold request is not generated (**Note**).

BUS REQUEST (DMAC) signal is sampled while the bus request sampling signal is “1” and is accepted (DMA request acceptance).

Figure 13.3.2 shows an example of timing from the determination of a DMA request until the DMA transfer execution.

Refer to section “13.9 DMA transfer time” for the time from DMA request generation until the CPU’s regaining the right to use bus via DMA transfer.

Note: In the following cases, BUS REQUEST (DMAC) does not go “1.” However, the DMAi request bit remains set to “1.” Accordingly, after completion of each state, the channel priority levels and bus use priority levels are determined, and BUS REQUEST (DMAC) goes “1” if any DRAM refresh request or Hold request is not generated.

- When a DMA request is generated during a burst transfer or in an array state (However, if a DRAM refresh request or Hold request is generated during this term, its BUS REQUEST goes “1.”)
- When a DMA request is not accepted with a DRAM refresh request or Hold request generated

EOL announced

DMA CONTROLLER

13.3 Control

Fig. 13.3.2 Example of timing from determination of DMA request until DMA transfer execution

13.3.5 Termination of DMA transfer

As the methods of terminating DMA transfer, normal and forced termination are used.

(1) Normal termination

All of the DMAi transfers terminate and DMAC stops. This method is used in the single transfer, array chain transfer, and link array chain transfer modes. In the repeat transfer mode, however, normal termination cannot be applied to terminating transfer; then, forced termination must be used. (Refer to “(2) Forced termination” of this section.)

Table 13.3.4 lists the states of DMAC at normal termination.

Table 13.3.4 States of DMAC at normal termination

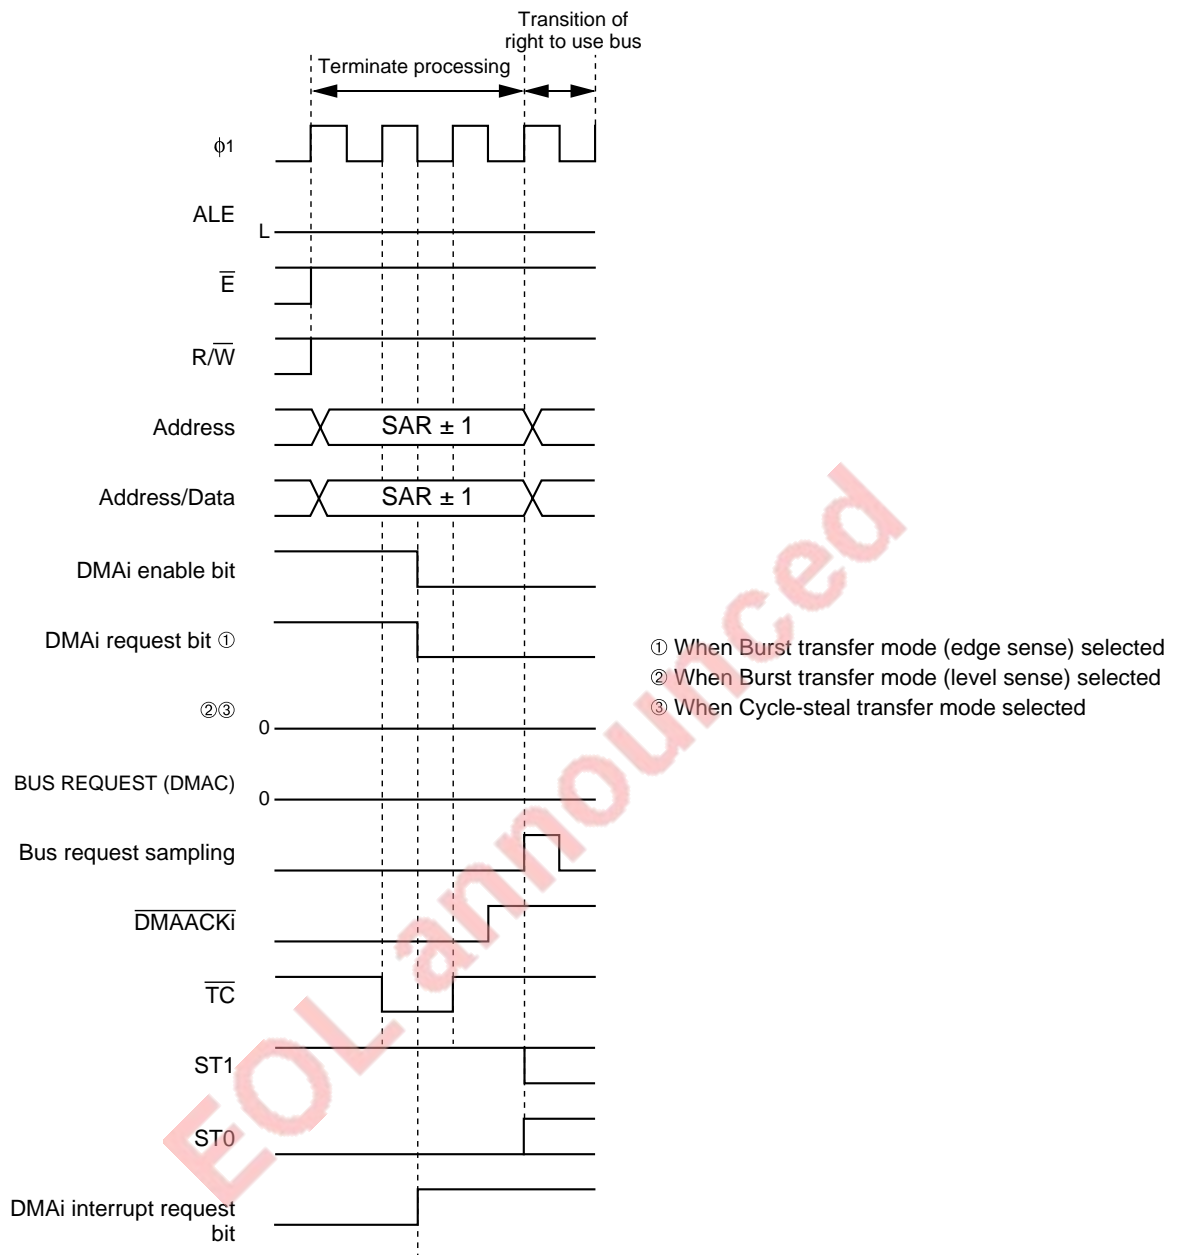

Item	State
DMAi interrupt request bit	1
DMAi request bit	In the burst transfer mode (edge sense): 0 In the burst transfer mode (level sense): not changed In the cycle-steal transfer mode: not changed (Note)
DMAi enable bit	0
$\overline{\text{TC}}$ output	Outputs “L” (when the $\overline{\text{TC}}$ pin is valid)
Channel priority levels	Rotating (when the rotating priority is selected)

Note: In the cycle-steal transfer mode, the DMAi request bit is cleared to “0” when a DMA request is accepted. This bit is does not change at normal termination.

At normal termination, the CPU regains the right to use bus after the terminate processing (3 cycles of ϕ) via the transition of the right to use bus (1 cycle of ϕ). Figure 13.3.3 shows a timing example at normal termination.

DMA CONTROLLER

13.3 Control

The above timing diagram applies on the following conditions:

- $\overline{\text{DMAACKi}}$ valid, \bar{TC} valid
- External source (DMAREQi)

Fig. 13.3.3 Timing example at normal termination

(2) Forced termination

The methods of terminating DMAC other than normal termination are as follows:

- Drives the \overline{TC} pin's input level from "H" to "L" during a DMA transfer (when the \overline{TC} pin is valid).
- Writes "0" to the DMAi enable bit.

Table 13.3.5 lists the states of DMAC at forced termination.

Table 13.3.5 States of DMAC at forced termination

Item	State
DMAi interrupt request bit	Not changed.
DMAi request bit	0
DMAi enable bit	0
\overline{TC} output	Not changed.
Channel priority levels	Not changed.

When the \overline{TC} pin is used for forced termination, select " \overline{TC} pin valid" (bit 1 at address $68_{16} = "1"$).

Forced termination by the \overline{TC} input is valid in the following cases:

- During a DMA transfer in the burst transfer mode (edge sense)
- During the term from the DMA transfer start until the transfer completion of an entire batch of data in the burst transfer mode with the level sense selected. (It is also valid while the CPU has the right to use bus).
- During a DMA transfer in the cycle-steal transfer mode (Forced termination by the \overline{TC} input is invalid while the CPU has the right to use bus.)

The \overline{TC} pin's input is determined at the falling edge of ϕ_1 , and DMAC will relinquish the right to use bus to the CPU upon completion of the 1-unit transfer under execution at that time.

At the forced termination by the DMAi enable bit, "0" is written to this bit at the rising edge of \overline{E} of a write cycle to the DMAi enable bit. Accordingly, DMAi is disabled after this write.

DMA CONTROLLER

13.3 Control

13.3.6 DMA transfer restart after termination

(1) Restarting the same DMA transfer as the previous one from the beginning

At normal and forced termination, the latches of SARi, DARi, and TCRI maintain their values written before the transfer start. (Refer to “**Figure 13.3.4-a.**”) Therefore, DMA transfer must be restarted according to the following procedures:

- **In single or repeat transfer mode**

Set the DMAi enable bit to “1.” It is not necessary to re-set the values of SARi, DARi, and TCRI by software. (Refer to “**Figure 13.3.4-b.**”)

- **In array chain or link array chain transfer mode**

- ① Re-set the values of SARi and TCRI.
- ② Set the DMAi enable bit to “1.”

(2) Restarting transfer of data subsequent to one which has been transferred just before forced termination

When reading values at the addresses of SARi, DARi, and TCRI after forced termination, the values of these registers (counters) can be read. These read values are the transfer source address, the transfer destination address which were to be transferred subsequently, and the number of remaining bytes.

When writing these read values to the addresses of SARi, DARi, and TCRI respectively, the same values are also written to their latches. When setting the DMAi enable bit to “1” under this condition, transfer of data subsequent to one which has been transferred just before forced termination is restarted. (Refer to “**Figure 13.3.4-c.**”)

- **In single transfer mode**

The remaining data can be transferred by the following procedure:

- ① Read the values at addresses of SARi, DARi and TCRI. Then, rewrite these values into these addresses.
- ② Set the DMAi enable bit to “1.”

- **In repeat transfer, array chain transfer, and link array chain transfer modes**

The remaining data of the block that was interrupted by forced termination can be transferred by the following procedure:

- ① Switch over the current mode to the single transfer mode.
- ② Read the values at addresses of SARi, DARi and TCRI. Then, rewrite these values into these addresses.
- ③ Set the DMAi enable bit to “1.” (Refer to “**Figure 13.3.4-c.**”)
- ④ In order to transfer the next block, switch over the current mode to the previous mode after the above-mentioned transfer is normally terminated. Then, re-set the values of SARi, DARi, and TCRI.

In the array chain or the link array chain transfer mode, information such as the next transfer parameters etc. cannot be read from each latch.

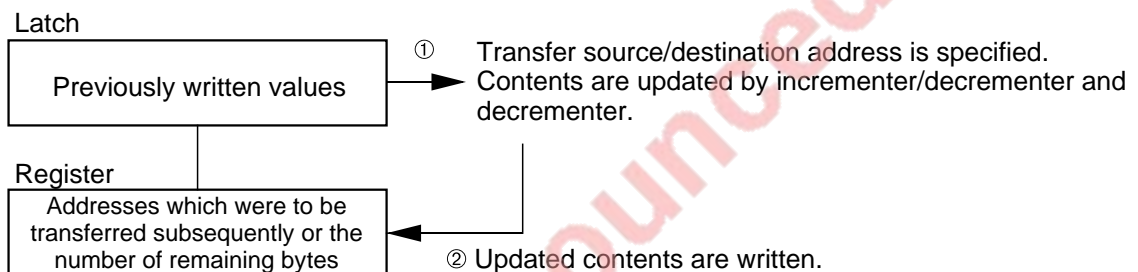

a. State at forced termination

b. When setting DMAi enable bit to "1" without rewriting values at addresses of SARi, DARI, and TCRI

A value read from each latch is used by hardware only at the first 1-unit transfer.

The contents updated by the incremter/decrementer and the decremter are loaded in each register. Values are used by reading them from registers at the second and the following 1-unit transfers.

c. When reading values at addresses of SARi, DARI, and TCRI after forced termination and rewriting them

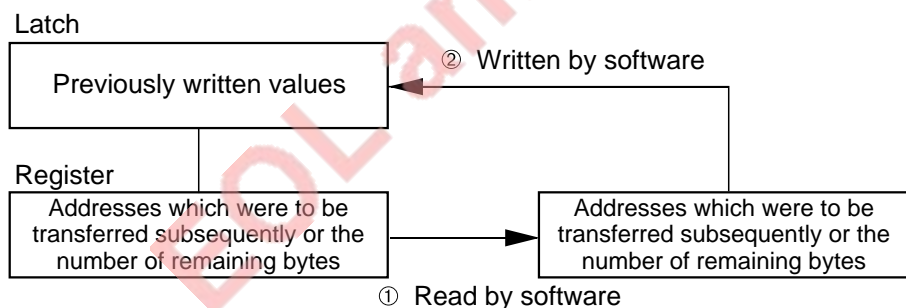

Fig.13.3.4 States of SARi, DARI, TCRI after forced termination

DMA CONTROLLER

13.4 Operation

13.4 Operation

Operation of 1-unit transfer varies according to the data transfer method (2-bus cycle or 1-bus cycle transfer). In addition, how many units of transfer data are transferred for a DMA request varies according to the transfer mode (burst transfer or cycle-steal transfer mode).

These data transfer methods and modes are described below.

13.4.1 2-bus cycle transfer

When the transfer method select bit (Refer to “**Figure 13.2.6.**”) = “0,” 2-bus cycle transfer is selected. 2-bus cycle transfer is the method used to transfer data between memories. Since this method has a read and a write cycle, it consumes a minimum of 2 bus cycles for 1-unit transfer.

Figure 13.4.1 shows an example of connecting external memories in 2-bus cycle transfer.

Fig. 13.4.1 Example of connecting external memories in 2-bus cycle transfer

(1) Register operation in 2-bus cycle transfer

Figure 13.4.2 shows a basic operation of registers for 1-unit transfer in 2-bus cycle transfer. For register values to be specified, refer to section “13.5 Single transfer mode” through section “13.8 Link array chain transfer mode.” It is because that these values vary according to continuous transfer modes.

In 2-bus cycle transfer, the data read at a read cycle is maintained temporarily in the DMA latch, and the contents of this latch are written to a memory at a write cycle.

Fig. 13.4.2 Basic operation of registers for 1-unit transfer in 2-bus cycle transfer

DMA CONTROLLER

13.4 Operation

(2) Bus operation in 2-bus cycle transfer

The time required for 1-unit transfer in 2-bus cycle transfer is given by the following formula:

$$\text{Transfer time per 1-unit transfer} = (\text{Read cycle}) + (\text{Write cycle})$$

Since any area can be specified as a transfer source or a transfer destination, a read cycle varies with the conditions of a transfer source, and a write cycle with that of a transfer destination.

Table 13.4.1 lists the time required for a read or write cycle per 1-unit transfer in 2-bus cycle transfer, and Figure 13.4.3 shows the bus-cycle operation waveforms in 2-bus cycle transfer.

Table 13.4.1 Time required for a read or write cycle per 1-unit transfer in 2-bus cycle transfer

External bus width	Transfer unit	Address directions	Data's start address	Read/Write cycle (Unit: ϕ cycle)			
				Formula	No Wait	With Wait	DRAM area
16 bits (including internal bus)	16 bits	Fixed/Forward	Even	$1 + i$	2 (a)	3 (d)	
			Odd	$2 + 2i$	4 (c)	6 (f)	
		Backward	Even	$2 + 2i$	4 (c)	6 (f)	
			Odd	$2 + i$	3 (b)	4 (e)	4 (e) (Note)
	8 bits	Fixed/Forward/Backward	Even/Odd	$1 + i$	2 (a)	3 (d)	
8 bits	16 bits	Fixed/Forward/Backward	Even/Odd	$2 + 2i$	4 (c)	6 (f)	
	8 bits	Fixed/Forward/Backward	Even/Odd	$1 + i$	2 (a)	3 (d)	

Address directions: Refer to section “13.4.1 (3) Address directions in 2-bus cycle transfer.”

i: A term of $\bar{E} = \text{“L”}$ in 1-bus cycle; $i = 1$ at “No Wait”, and $i = 2$ at “With Wait” or “DRAM area”.

When Ready function is used (Refer to section “3.3 Ready function.”), the number of cycles extended by Ready must be added.

(): Indicates the corresponding waveform in Figure 13.4.3.

Note: When a transfer destination applies to this condition, 2-bus cycle transfer cannot be performed. When a transfer source applies to this condition and a transfer destination is in the DRAM area, 2-bus cycle transfer cannot also be performed.

Fig. 13.4.3 Bus-cycle operation waveforms in 2-bus cycle transfer

DMA CONTROLLER

13.4 Operation

(3) Address directions in 2-bus cycle transfer

In 2-bus cycle transfer, the address direction of a transfer source and that of a transfer destination each can be selected independently. (Refer to “Figure 13.2.6.”) Addresses move in the specified direction by the transfer unit. Tables 13.4.2 through 13.4.4 list address directions in 2-bus cycle transfer and examples of transfer result.

[Precautions for 2-bus cycle transfer]

When the 16-bit external data bus width = 16 bits and the transfer unit = 16 bits under the following conditions, 2-bus cycle transfer cannot be performed. (Refer to “**Table 13.4.1.**”)

- **Conditions for transfer destination**

Transfer destination = DRAM area, Address direction = Backward, Data's start address = Odd address

- **Conditions for transfer source and destination**

Transfer source = DRAM area, Address direction = Backward, Data's start address = Odd address
Transfer destination = DRAM area

EOL announced

DMA CONTROLLER

13.4 Operation

13.4.2 1-bus cycle transfer

When the transfer method select bit (Refer to “Figure 13.2.6.”) = “1,” 1-bus cycle transfer is selected. 1-bus cycle transfer is the method used to transfer data between a memory and an I/O. In this method, a read and write of 1-transfer-unit data are simultaneously performed during 1-bus cycle. The address bus, \overline{BHE} , \overline{BLE} , and R/\overline{W} indicate the states of memory.

Figure 13.4.4 shows an example of connecting external memories and I/Os in 1-bus cycle transfer.

Fig. 13.4.4 Example of connecting external memories and I/Os in 1-bus cycle transfer

In 1-bus cycle transfer, the following considerations must be taken in designing the system:

- Achieve the condition that 1-transfer-unit data can be accessed in 1-bus cycle. (Refer to “Table 13.4.5.”)
- Specify the transfer address direction and I/O connections. (Refer to “Figure 13.2.7.”)
- Compose the read and write signal generating circuit externally. (These signals are for I/Os.)

The M37721 outputs signals to the memory. Accordingly, make sure to compose the circuit which generates write signals for I/Os when the M37721 outputs read signals; which generates read signals for I/Os when the M37721 outputs write signals. Figure 13.4.5 shows an example of the circuit generating a write signal and a read signal for I/Os.

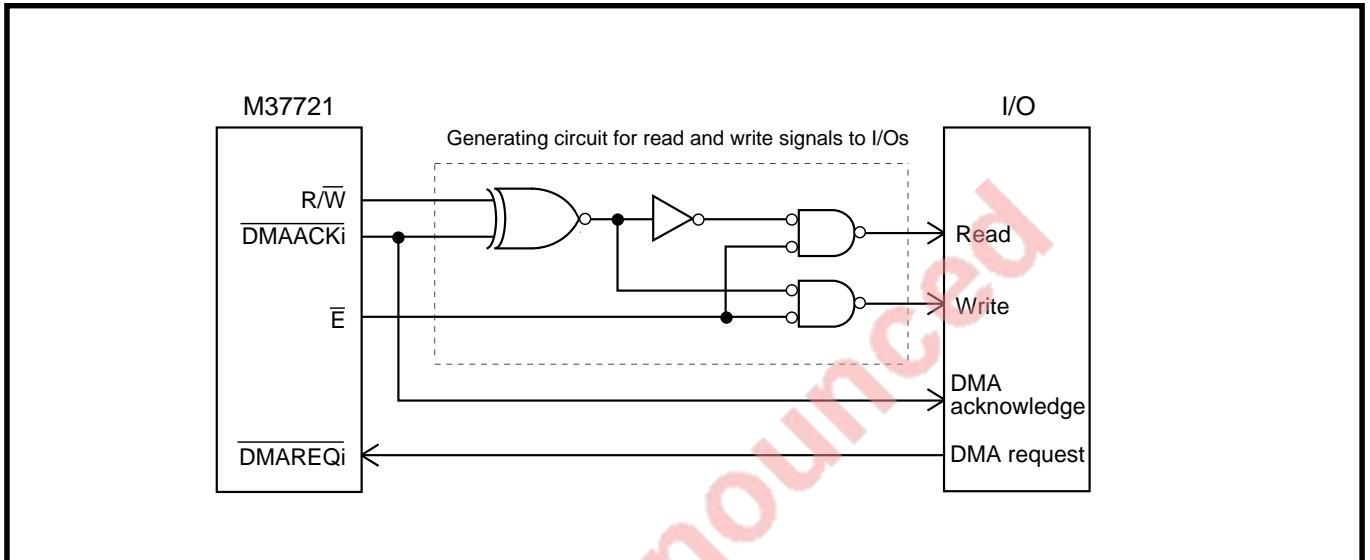

Fig. 13.4.5 Example of circuit generating write signal and read signal for I/Os

DMA CONTROLLER

13.4 Operation

(1) Register operation in 1-bus cycle transfer

Figure 13.4.6 shows a basic operation of registers for 1-unit transfer in 1-bus cycle transfer. For register values to be specified, refer to section “13.5 Single transfer mode” through section “13.8 Link array chain transfer mode.” It is because these values vary depending on each continuous transfer mode. In 1-bus cycle transfer, a read and write of 1-transfer-unit data are simultaneously performed during 1-bus cycle.

Fig. 13.4.6 Basic operation of registers for 1-unit transfer in 1-bus cycle transfer

(2) Bus operation in 1-bus cycle transfer

The time required for 1-unit transfer in 1-bus cycle transfer is given by the following formulas:

- Transfer from memory to I/O: Transfer time per 1-unit transfer = (Read cycle of memory)
- Transfer from I/O to memory: Transfer time per 1-unit transfer = (Write cycle of memory)

In 1-bus cycle transfer, 1-transfer-unit data is accessed in 1-bus cycle, so that limitations are imposed on the transfer conditions to be applied. Table 13.4.5 lists the conditions of 1-bus cycle transfer and the transfer time per 1-unit transfer, and Figure 13.4.7 shows the bus-cycle operation waveforms in 1-bus cycle transfer.

Table 13.4.5 Conditions of 1-bus cycle transfer and Transfer time per 1-unit transfer

External bus width	Transfer unit	Address directions	Data's start address	Read/Write cycle (Unit: ϕ cycle)				
				Formula	No Wait	With Wait	DRAM area	
16 bits (including internal bus)	16 bits	Fixed/Forward	Even	$1 + i$	2 (a)	3 (c)		
			Odd					
		Backward	Even					
			Odd	$2 + i$	3 (b)	4 (d)		
	8 bits	Fixed/Forward/Backward	Even/Odd	$1 + i$	2 (a)	3 (c)		
8 bits	16 bits	Fixed/Forward/Backward	Even/Odd					
	8 bits	Fixed/Forward/Backward	Even/Odd	$1 + i$	2 (a)	3 (c)		

Address directions: Refer to section “13.4.2 (3) Address directions in 1-bus cycle transfer.”

There is no address direction on the I/O side.

i: A term of $\bar{E} = 'L'$ in 1-bus cycle; $i = 1$ at “No Wait”, and $i = 2$ at “With Wait” or “DRAM area”.

When Ready function is used (Refer to section “3.3 Ready function.”), the number of cycles extended by Ready must be added.

(): Indicates the corresponding waveform in Figure 13.4.7.

/: 1-bus cycle transfer cannot be performed.

When the external data bus width = 16 bits and the transfer unit = 8 bits are selected, the data bus which the memory uses and the data bus to which I/O is connected may be different. In such a case, data is copied from the data bus of a transfer source to that of a transfer destination by using the DMA latch. For the combination that data copy may occur, data copy delay time $t_{d(data)}$ must be taken into consideration.

Table 13.4.6 lists the data flows on the data bus in 1-bus cycle transfer, and Table 13.4.7 lists the outputs of the address bus, the data bus, and the bus control signals in 1-bus cycle transfer.

* : Transfer start

[Precautions for 1-bus cycle transfer]

1. The area that overlaps with internal RAM and SFRs must not be assigned to an external memory.
When the contents in the overlapped area are read, the data of internal RAM or SFRs and that of external memory are simultaneously placed on the data bus; and they collide with each other.
2. For the system that transfers data with 16-bit external data bus width from an external memory to an 8-bit I/O, the external memory must be composed to be read in a unit of 8 bits.
If the external memory cannot be read in a unit of 8 bits, the data read from the external memory at data copy collides with the copied data on the data bus.
3. Under the following conditions, 1-bus cycle transfer cannot be performed. (Refer to “**Table 13.4.5.**”):
 - External data bus width = 16 bits, Transfer unit = 16 bits, Address direction of memory = Fixed or Forward, Data's start address of memory = Odd
 - External data bus width = 16 bits, Transfer unit = 16 bits, Address direction of memory = Backward, Data's start address of memory = Even
 - External data bus width = 16 bits, Transfer unit = 16 bits, Target memory of DMA transfer = DRAM area, Address direction of memory = Backward, Data's start address of memory = Odd
 - External data bus width = 8 bits, Transfer unit = 16 bits

EOL announced

DMA CONTROLLER

13.4 Operation

13.4.3 Burst transfer mode

The burst transfer mode can operate in either edge sense or level sense mode.

(1) Burst transfer mode (edge sense)

When the transfer mode select bit = "0" and the edge sense/level sense select bit = "0," this mode is selected. (Refer to "Figures 13.2.6 and 13.2.8.")

In this mode, all of the DMA request sources are available.

Figure 13.4.8 shows a transfer example in the burst transfer mode (edge sense).

When once a DMA request is accepted in this mode, an entire batch of data is transferred: the right to use bus is not returned to the CPU until the transfer is complete.

During a burst transfer, any DMA request (including that of other channels) cannot be accepted. However, the BUS REQUEST signal is sampled basically at every completion of 1-unit transfer. (Refer to "Table 13.2.3.") When a DRAM refresh request or Hold request is generated at this time, the right to use bus is not returned to the CPU, and the request is accepted.

When the transfer of an entire batch of data is complete, the DMAC relinquishes the right to use bus to the CPU. When the next DMA request is generated, the right is once returned to the CPU to sample the DMA request.

(2) Burst transfer mode (level sense)

When the transfer mode select bit = "0" and the edge sense/level sense select bit = "1," this mode is selected. (Refer to "Figures 13.2.6 and 13.2.8.")

In this mode, only the external source is used as a DMA request source. Set the DMA request source select bits to "0001₂." (Refer to "Figure 13.2.8.")

Figure 13.4.9 shows a transfer example in the burst transfer mode (level sense).

When the $\overline{\text{DMAREQ}}_i$ pin's input level = "L," the DMA_i request bit is cleared to "0"; when this pin's input level = "L," the DMA_i request bit is set to "1."

Therefore, when the $\overline{\text{DMAREQ}}_i$ pin's input level is "L" with the DMA_i enable bit = "1," a DMA transfer starts. When the $\overline{\text{DMAREQ}}_i$ pin's input level goes from "L" to "H," the right to use bus will be returned to the CPU at completion of 1-unit transfer under execution at that time. When the $\overline{\text{DMAREQ}}_i$ pin's input level goes "L" again, the DMA transfer restarts at the next address.

Once a DMA_i transfer starts, any DMA request (including that of other channels) cannot be accepted, even if the $\overline{\text{DMAREQ}}_i$ pin's input level is "H," until the transfer is terminated normally or forcibly. However, the BUS REQUEST signal is sampled basically at every completion of 1-unit transfer. (Refer to "Table 13.2.3.") When a DRAM refresh request or Hold request is generated at this time, the right to use bus is not returned to the CPU, and the request is accepted.

When the transfer of an entire batch of data is complete, the DMAC relinquishes the right to the CPU. If the next DMA request is generated, the right is once returned to the CPU to sample the DMA request.

Fig. 13.4.8 Transfer example in the burst transfer mode (edge sense)

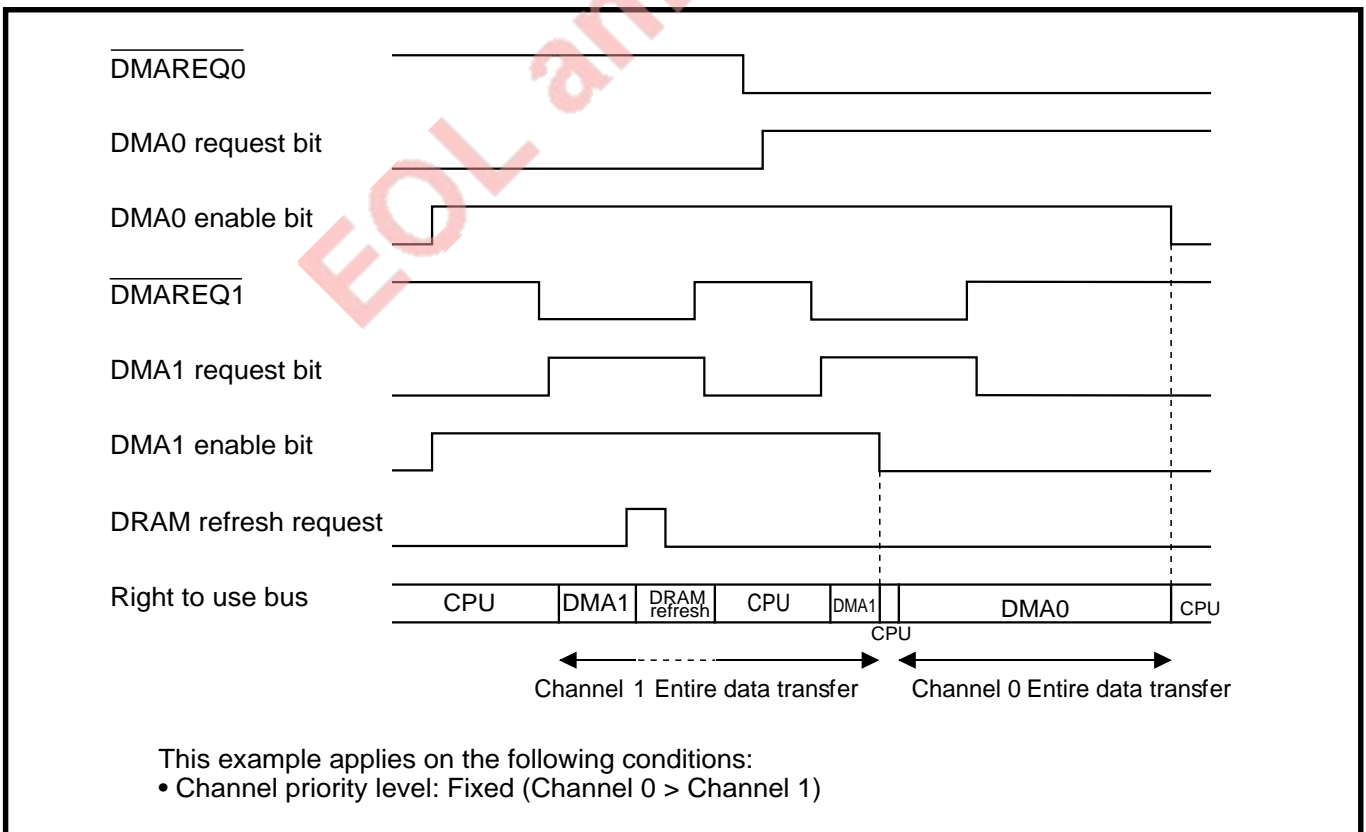

Fig. 13.4.9 Transfer example in the burst transfer mode (level sense)

DMA CONTROLLER

13.4 Operation

[Precautions for burst transfer mode]

1. In the burst transfer mode (edge sense), the DMAi request bit is cleared to "0" when the transfer of an entire batch of data is complete or the transfer is forced into termination. Therefore, another DMA request of the same channel i is invalid if generated during DMAi transfer.

Fig. 13.4.10 Timing when clearing DMAi request bit to "0" in burst transfer mode

2. Because interrupt priority levels are determined while the CPU fetches an operation code, interrupt requests are not accepted during a DMA transfer. In the burst transfer mode (edge sense), therefore, interrupt requests cannot be accepted until the transfer of an entire batch of data is complete or the transfer is forced into termination.

13.4.4 Cycle-steal transfer mode

When the transfer mode select bit = "1" and the edge sense/level sense select bit = "0," this mode is selected. (Refer to "Figures 13.2.6 and 13.2.8.")

In this mode, all of the DMA request sources are available.

Figure 13.4.11 shows a transfer example in the cycle-steal transfer mode
1-transfer-unit data is transferred for each DMA request.

The BUS REQUEST signal is sampled basically at every completion of 1-unit transfer. (Refer to "Table 13.2.3.") When a DRAM refresh request or Hold request is generated at this time, the right to use bus is not returned to the CPU, and the request is accepted. When several DMA requests are generated, the request of the channel which has the highest priority among them is accepted, and DMA transfer is performed without returning the right to use bus to the CPU. When any request is not generated, the CPU gains the right.

Fig. 13.4.11 Transfer example in cycle-steal transfer mode

DMA CONTROLLER

13.4 Operation

[Precautions for cycle-steal transfer mode]

1. When DMA transfers of the same channel are continuously performed

In the cycle-steal transfer mode, the DMAi request bit is cleared to "0" in every 1-unit transfer. Also, it takes 1.5 cycles of ϕ from the generation of a DMA request until that of a BUS REQUEST (DMAC). Therefore, if another DMA request of the same channel i is generated during a DMAi transfer in the cycle-steal transfer mode, any one of the following three cases occurs depending on the timing of request generation:

- The DMA request becomes invalid.
- The DMA transfer continues without returning the right to use bus.
- After returning the right to use bus to the CPU, the DMAC regains the right and restarts the DMA transfer.

Fig. 13.4.12 Conditions for performing DMA transfers of the same channel continuously

2. When a DMA transfer of another channel is subsequently performed

In the cycle-steal transfer mode, it takes 1.5 cycles of ϕ from the generation of a DMA request until that of a BUS REQUEST (DMAC).

Therefore, if a DMA request of another channel is generated during a DMAi transfer in the cycle-steal mode, either one of the following two cases occurs depending on its timing of request generation:

- The DMAC performs the DMA transfer subsequently without returning the right to use bus.
- After returning the right to use bus to the CPU once, the DMAC regains the right and performs the DMA transfer.

Fig. 13.4.13 Conditions for performing DMA transfers of another channel subsequently

DMA CONTROLLER

13.5 Single transfer mode

13.5 Single transfer mode

This mode is used to transfer a block of data once.

Table 13.5.1 lists the specifications of the single transfer mode, and Figure 13.5.1 shows the register structures of SAR_i, DAR_i, and TCR_i in this mode.

Table 13.5.1 Specifications of single transfer mode

Item	Performance specifications
Transfer parameter memory	Not required.
Condition of normal termination	TCR _i = 0
Conditions of forced termination	<ul style="list-style-type: none">● Falling edge of the $\overline{\text{TC}}$ pin's input from "H" to "L" (when the $\overline{\text{TC}}$ pin validity bit = "1")● Write "0" to the DMA_i enable bit
Interrupt request generation timing	At normal termination
Functions of registers	SAR _i latch: Indicates the transfer start address of data block at the transfer source. SAR _i : Indicates the address of the next transfer source. DAR _i latch: Indicates the transfer start address of data block at the transfer destination. DAR _i : Indicates the address of the next transfer destination. TCR _i latch: Indicates the number of transfer bytes. TCR _i : Indicates the number of remaining transfer bytes.

$\overline{\text{TC}}$ pin validity bit: Bit 1 at address 68₁₆

13.7 Array chain transfer mode

13.7 Array chain transfer mode

This mode is used to transfer several blocks of data. According to the information of each block stored in memory area (**Note**), several blocks of data are transferred. All of the transfer parameters must be located in series. Table 13.7.1 lists the specifications of the array chain transfer mode, and Figure 13.7.1 shows the register structures of SARi, DARI, and TCRi in this mode.

Note: Each of the following information is called “transfer parameter”: transfer start addresses of transfer source and destination, and transfer data’s byte number.

Table 13.7.1 Specifications of array chain transfer mode

Item	Performance specifications
Transfer parameter memory	Required. <ul style="list-style-type: none">● In 2-bus cycle transfer: 12 bytes per one block (transfer source’s transfer start address, transfer destination’s transfer start address, transfer data’s byte number)● In 1-bus cycle transfer: 8 bytes per one block (from memory to I/O: transfer source’s transfer start address, transfer data’s byte number) (from I/O to memory: transfer destination’s transfer start address, transfer data’s byte number)
Condition of normal termination	TCRi latch = 0 and TCRi = 0
Conditions of forced termination	<ul style="list-style-type: none">● Falling edge of the \overline{TC} pin’s input from “H” to “L” (when the \overline{TC} pin validity bit = “1”)● Write “0” to the DMAi enable bit
Interrupt request generation timing	At normal termination
Functions of registers	SARi latch: Indicates the transfer parameter memory’s start address of the next block. SARi: Indicates the address of the next transfer source. DARI latch: Not used. DARI: Indicates the address of the next transfer destination. TCRi latch: Indicates the number of remaining transfer blocks. TCRi: Indicates the number of remaining transfer bytes.

\overline{TC} pin validity bit: Bit 1 at address 68₁₆

13.7.1 Transfer parameter memory in array chain transfer mode

The transfer parameters required for each transfer method are described below. These parameters must be located in series starting at an even addresses.

Figure 13.7.2 shows a transfer parameter memory map in the array chain transfer mode.

(1) In 2-bus cycle transfer

All of the following transfer parameters are required for each block of data; that is, a transfer parameter memory consumes 12 bytes for each block.

- Transfer source's transfer start address (24 bits) + Dummy data (8 bits)
- Transfer destination's transfer start address (24 bits) + Dummy data (8 bits)
- Transfer data's byte number (24 bits) + Dummy data (8 bits)

(2) In 1-bus cycle transfer from memory to I/O

All of the following transfer parameters are required for each block of data; that is, a transfer parameter memory consumes 8 bytes for each block.

- Transfer source's transfer start address (24 bits) + Dummy data (8 bits)
- Transfer data's byte number (24 bits) + Dummy data (8 bits)

(3) In 1-bus cycle transfer from I/O to memory

All of the following transfer parameters are required for each block of data; that is, a transfer parameter memory consumes 8 bytes for each block.

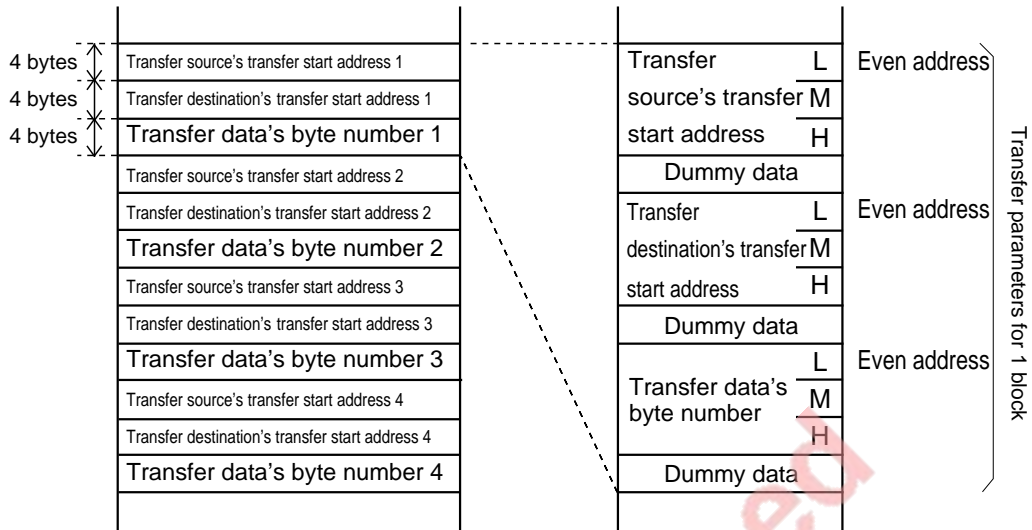

- Transfer destination's transfer start address (24 bits) + Dummy data (8 bits)
- Transfer data's byte number (24 bits) + Dummy data (8 bits)

13.7.3 Operation in array chain transfer mode

Figure 13.7.6 shows the operation flowchart of the array chain transfer mode, and Figures 13.7.7 and 13.7.8 show timing diagrams of the array chain transfer mode (burst transfer mode).

For the cycle-steal transfer mode, refer to the following:

- Transfer of transfer parameters in an array state: Figures 13.8.10 and 13.8.11
- All transfers except in an array state and except the last 1-unit transfer of each block: Figure 13.8.12
- Last 1-unit transfer of each block except the last block: Figure 13.8.13
- Last 1-unit transfer of the last block: Figure 13.8.14

The processing performed in the array chain transfer mode consists of an array state and a transfer state.

(1) Array state

In an array state, transfer parameters are read from the transfer parameter memory in a unit of 2 bytes and transferred to registers SAR_i, DAR_i, and TCR_i and their latches. As shown in Figure 13.7.2, a transfer parameter consists of 4 bytes (24 bits of data + 8 bits of dummy data).

One bus cycle always consumes 3 cycles of ϕ .

During an array state, the $\overline{\text{DMAACK}}_i$ pin outputs "H" level.

For the bus request sampling in an array state, refer to section "13.2.1 Bus access control circuit."

(2) Transfer state

Data is transferred in a transfer state.

For the bus request sampling in a transfer state, refer to section "13.2.1 Bus access control circuit."

DMA CONTROLLER

13.8 Link array chain transfer mode

● **Initial term for processing each block in array chain and link array chain transfer modes**

The operation from an array state to the first 1-unit transfer is continuously performed by one DMAi request.

Continue to "Figure 13.8.11." →

● The above figure is the example of initial term for processing the first block in "Figure 13.8.9."

● The Bus request caused by DRAM refresh or Hold is sampled while the bus request sampling signal is "1," and is accepted.

● The Bus request caused by DMA is sampled while the bus request sampling signal (*1) is "1" in the transition of the right to use bus, and is accepted.
 The DMA requests of the other channels are not accepted in an array state.

Fig. 13.8.10 Timing diagram of cycle-steal transfer mode (1)

- The above figure is the example of initial term for processing the first block in "Figure 13.8.9." When the array chain transfer mode is selected, there is not the term of *2.
- The Bus request caused by DRAM refresh or Hold is sampled while the bus request sampling signal is "1," and is accepted.
- The Bus request caused by DMA is sampled while the bus request sampling signal (*1) is "1" in transition of the right to use bus, and is accepted. The DMA requests of the other channels are not accepted in an array state.

Fig. 13.8.11 Timing diagram of cycle-steal transfer mode (2)

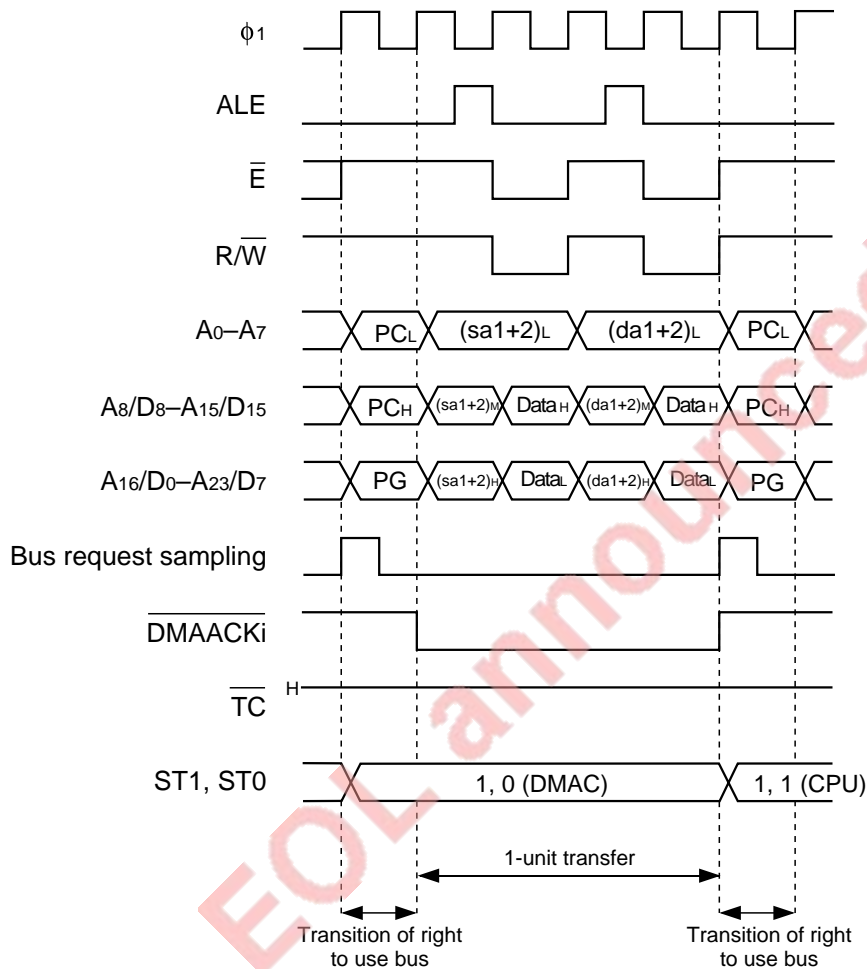

DMA CONTROLLER

13.8 Link array chain transfer mode

● 1-unit transfer

1-unit transfer is performed with a DMAi request on the following conditions:

- Single transfer mode (except for the last 1-unit transfer)
- Repeat transfer mode (except for the last 1-unit transfer of block)
- Array chain transfer mode (except for the first and last 1-unit transfers of each block)
- Link array chain transfer mode (except for the first and last 1-unit transfers of each block)

- The above figure is the example of the second 1-unit transfer for processing the first block in “Figure 13.8.9.”
- The Bus request caused by DRAM refresh, Hold, or DMA is sampled while the Bus request sampling signal is “H,” and is accepted.

Fig. 13.8.12 Timing diagram of cycle-steal transfer mode (3)

DMA CONTROLLER

13.8 Link array chain transfer mode

● Last transfer of each block

At the last term (except for the last block) for processing of each block in the repeat, array chain, and link array chain transfer modes, 1-unit transfer is performed with one DMAi request, and the right to use bus is relinquished after 3 cycles of ϕ .

- The above figure is the example of the last term for processing the first block in "Figure 13.8.9."
- The Bus request caused by DRAM refresh, Hold, or DMA is sampled while the bus request sampling signal is "H," and is accepted.

Fig. 13.8.13 Timing diagram of cycle-steal transfer mode (4)

DMA CONTROLLER

13.8 Link array chain transfer mode

● Last transfer of last block

At the last term for processing the last block in the single, array chain, and link array chain transfer modes, 1-unit transfer and terminate processing are subsequently performed with one DMAi request.

- The above figure is the example of the last term for processing the second block in “Figure 13.8.9.”
- The Bus request caused by DRAM refresh, Hold, or DMA is sampled while the bus request sampling signal is “H,” and is accepted.

Fig. 13.8.14 Timing diagram of cycle-steal transfer mode (5)

[Precautions for link array chain transfer mode]

If the following two conditions are satisfied when the transfer unit is 16 bits and the address direction of transfer source or destination is fixed, the link array chain transfer mode can be used:

- The external data bus width = 16 bits or the internal memory is used.
- The transfer start address on the address-direction-fixed side is an even address.

EOL announced

DMA CONTROLLER

13.9 DMA transfer time

13.9 DMA transfer time

Calculation of time from the CPU's relinquishing the right to use bus until its regaining the right under the following conditions is described with reference to cycles of ϕ :

- A DMAi request is generated while the CPU holds the right to use bus.
- The above right is returned to the CPU after completion of DMA transfer for one DMA request.

For the time per 1-unit transfer, refer to section “13.4.1 (2) Bus operation in 2-bus cycle transfer” and section “13.4.2 (2) Bus operation in 1-bus cycle transfer.”

Also, for the time from DMA request generation until the start of the DMA transfer, refer to section “13.3.4 Processing from DMA request until DMA transfer execution”: and for that from issuing instructions for forced termination until returning the right to use bus to the CPU, refer to section “13.3.5 (2) Forced termination.”

13.9.1 Cycle-steal transfer mode

(1) 1-unit transfer

In the following cases, 1-unit transfer is performed at one DMAi transfer. (Refer to “Figure 13.8.12.”)

- Single transfer mode: except for the last 1-unit transfer
- Repeat transfer mode: except for the last 1-unit transfer of a block
- Array chain transfer mode: except for the first and last 1-unit transfers of each block
- Link array chain transfer mode: except for the first and last 1-unit transfers of each block

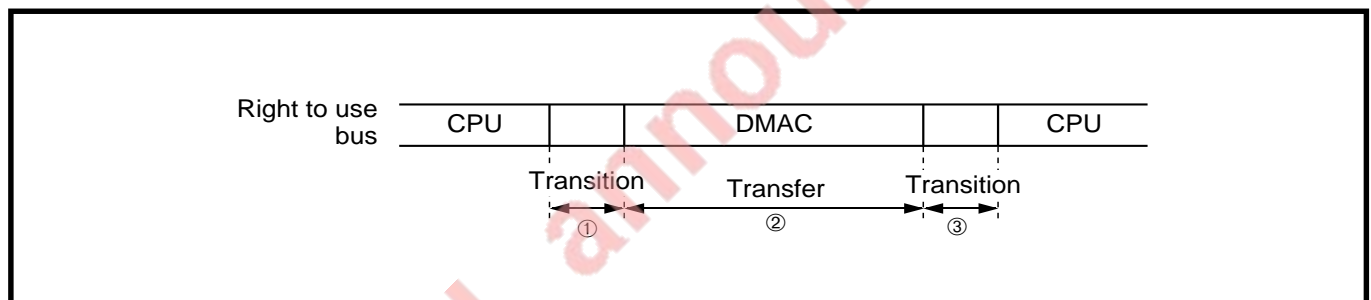

Fig. 13.9.1 1-unit transfer

- ① Transition of the right to use bus from CPU to DMAC: 1 cycle
- ② DMA transfer per 1-transfer unit:
 - In 2-bus cycle transfer...Read cycle + Write cycle
(Add a value which satisfies the read/write conditions. Refer to “Table 13.4.1.”)
 - In 1-bus cycle transfer...Refer to “Table 13.4.5.”
- ③ Transition of the right to use bus from DMAC to CPU: 1 cycle

[Example]

2-bus cycle transfer, transfer unit = 16 bits, external data bus width = 16 bits, and under the following conditions:

- Transfer source: address direction = forward, start address of data = even, with Wait
- Transfer destination: address direction = backward, start address of data = even, without Wait

$$\textcircled{1} + \textcircled{2} + \textcircled{3} = 1 + (3 + 4) + 1 = 9 \text{ cycles}$$

(2) Last transfer of each block

In the following cases, 1-unit transfer and the processing for 3 cycles are performed sequentially. (Refer to “**Figures 13.8.13 and 13.8.14.**”)

- Single transfer mode: the last 1-unit transfer
- Repeat transfer mode: the last 1-unit transfer of a block
- Array chain transfer mode: the last 1-unit transfer of each block (including the last block)
- Link array chain transfer mode: the last 1-unit transfer of each block (including the last block)

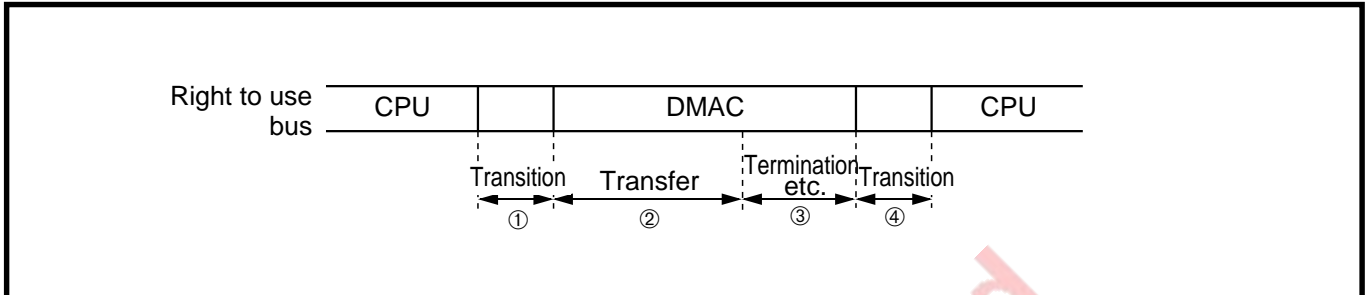

Fig. 13.9.2 Last transfer of each block

- ① Transition of the right to use bus from CPU to DMAC: 1 cycle
- ② DMA transfer per 1-unit transfer:
 - In 2-bus cycle transfer...Read cycle + Write cycle
(Add a value which satisfies the read/write conditions. Refer to “**Table 13.4.1.**”)
 - In 1-bus cycle transfer...Refer to “**Table 13.4.5.**”
- ③ Terminate processing or the last processing of each block: 3 cycles
- ④ Transition of the right to use bus from DMAC to CPU: 1 cycle

[Example]

2-bus cycle transfer, transfer unit = 16 bits, external data bus width = 16 bits, and under the following conditions:

- Transfer source: address direction = forward, start address of data = even, with Wait
- Transfer destination: address direction = backward, start address of data = even, without Wait

$$\text{①} + \text{②} + \text{③} + \text{④} = 1 + (3 + 4) + 3 + 1 = 12 \text{ cycles}$$

DMA CONTROLLER

13.9 DMA transfer time

(3) Transfer of array state

In the following cases, the processing in an array state and the first 1-unit transfer are performed sequentially. (Refer to “**Figures 13.8.10 and 13.8.11.**”)

- Array chain transfer mode: the first transfer of each block
- Link array chain transfer mode: the first transfer of each block

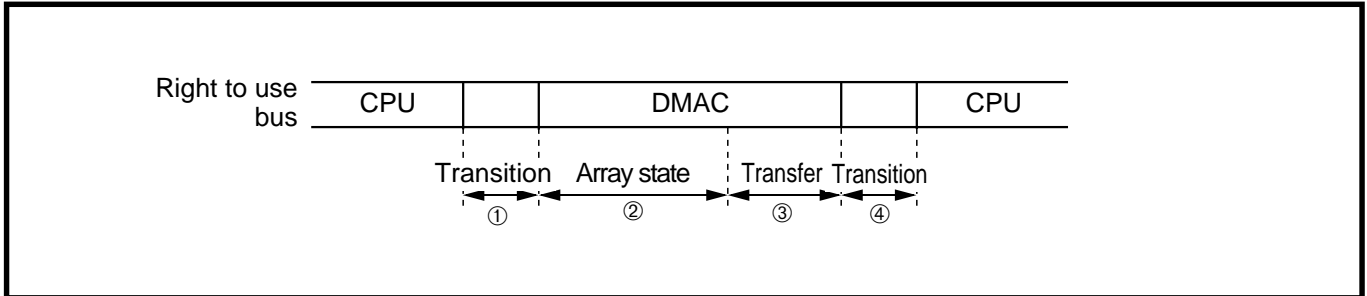

Fig. 13.9.3 Transfer of array state

- ① Transition of the right to use bus from CPU to DMAC: 1 cycle
- ② Array state:
The number of transfer parameters × the number of reads of a transfer parameter × the number of bus cycles for a read + 1 cycle (Refer to “**Table 13.9.1.**”)
- ③ DMA transfer per 1-unit transfer:
 - In 2-bus cycle transfer...Read cycle + Write cycle
(Add a value which satisfies the read/write conditions. Refer to “**Table 13.4.1.**”)
 - In 1-bus cycle transfer...Refer to “**Table 13.4.5.**”
- ④ Transition of the right to use bus from DMAC to CPU: 1 cycle

[Example]

Link array chain transfer mode, external data bus width = 16 bits, 2-bus cycle transfer, transfer unit =16 bits, and under the following conditions:

- Transfer source: address direction = forward, start address of data = even, with Wait
 - Transfer destination: address direction = backward, start address of data =odd, with Wait
- ① + ② + ③ + ④ = 1 + 25 + (3 + 4) + 1 = 34 cycles

Table 13.9.1 Time required for processing in array state

Mode	External data bus width	Transfer method	Number of transfer parameters	Number of reads of a transfer parameter	Time required for processing in array state (Unit: ϕ cycle)
Array chain transfer mode	16 bits (Including internal bus)	2-bus cycle transfer	3	2	$3 \times 2 \times 3 + 1 = 19$
		1-bus cycle transfer	2	2	$2 \times 2 \times 3 + 1 = 13$
	8 bits	2-bus cycle transfer	3	4	$3 \times 4 \times 3 + 1 = 37$
		1-bus cycle transfer	2	4	$2 \times 4 \times 3 + 1 = 25$
Link array chain transfer mode	16 bits (Including internal bus)	2-bus cycle transfer	4	2	$4 \times 2 \times 3 + 1 = 25$
		1-bus cycle transfer	3	2	$3 \times 2 \times 3 + 1 = 19$
	8 bits	2-bus cycle transfer	4	4	$4 \times 4 \times 3 + 1 = 49$
		1-bus cycle transfer	3	4	$3 \times 4 \times 3 + 1 = 37$

13.9.2 Burst transfer mode

(1) Single transfer mode

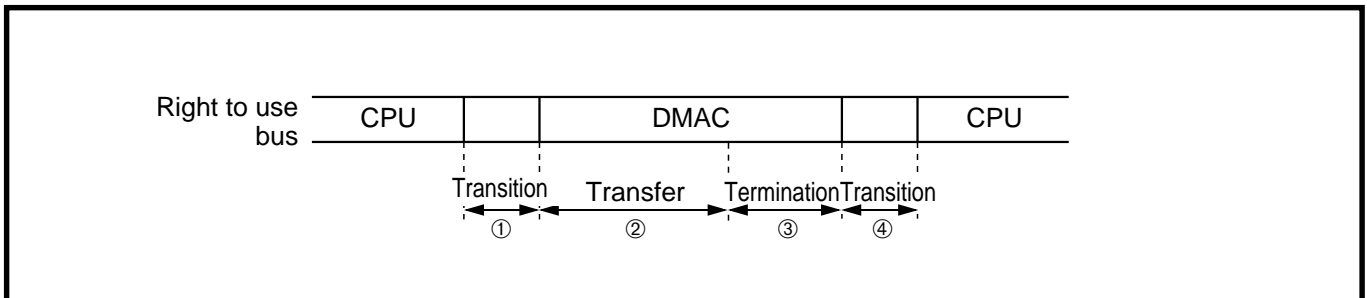

Fig. 13.9.4 Single transfer mode (burst transfer mode selected)

- ① Transition of the right to use bus from CPU to DMAC: 1 cycle
- ② DMA transfer per an entire batch of data:
 - In 2-bus cycle transfer... $(\text{Read cycle} + \text{Write cycle}^{*1}) \times \text{the number of transfers}^{*2}$
 - *1: Add a value which satisfies the read/write conditions. Refer to “Table 13.4.1.”
 - *2: When the transfer unit is 16 bits, the number of transfers = the number of transfer bytes/2
 - When the transfer unit is 8 bits, the number of transfers = the number of transfer bytes
 - In 1-bus cycle transfer...Refer to “Table 13.4.5.”
- ③ Terminate processing: 3 cycles
- ④ Transition of the right to use bus from DMAC to CPU: 1 cycle

[Example]

External data bus width = 16 bits, 2-bus cycle transfer, transfer unit =16 bits, the number of the transfer bytes = 10 bytes, and under the following conditions:

- Transfer source: address direction = forward, start address of data = even, with Wait
- Transfer destination: address direction = backward, start address of data = even, without Wait

$$\text{①} + \text{②} + \text{③} + \text{④} = 1 + 5 (3 + 4) + (3 + 1) = 40 \text{ cycles}$$

DMA CONTROLLER

13.9 DMA transfer time

(2) Repeat transfer mode

In the repeat transfer mode of burst transfer (edge sense), the method of terminating DMA transfer is only the forced termination by the \overline{TC} input. Therefore, the time from the CPU's relinquishing the right to use bus until regaining the right depends on the timing of the \overline{TC} input.

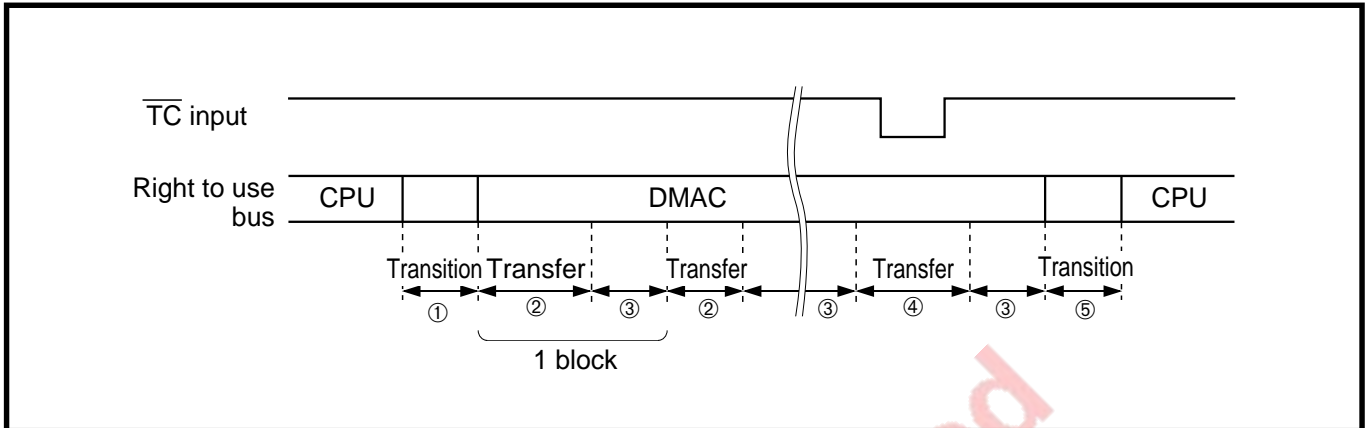

Fig. 13.9.5 Repeat transfer mode (burst transfer mode and edge sense selected)

- ① Transition of the right to use bus from CPU to DMAC: 1 cycle
- ② DMA transfer per 1 block:
 - In 2-bus cycle transfer... $(\text{Read cycle} + \text{Write cycle}^{*1}) \times \text{the number of transfers}^{*2}$
 - *1: Add a value which satisfies the read/write conditions. Refer to "Table 13.4.1."
 - *2: When the transfer unit is 16 bits, the number of transfers = the number of transfer bytes/2
 - When the transfer unit is 8 bits, the number of transfers = the number of transfer bytes
 - In 1-bus cycle transfer...Refer to "Table 13.4.5."
- ③ Terminate processing: 3 cycles
- ④ DMA transfer of the block at the \overline{TC} input: above ②
The number of transfers is assumed to be up to the DMA transfer of 1-unit transfer which was in progress at the \overline{TC} input.
- ⑤ Transition of the right to use bus from DMAC to CPU: 1 cycle

[Example]

External data bus width = 16 bits, 2-bus cycle transfer, transfer unit = 16 bits, the number of the transfer bytes = 10 bytes, and under the following conditions:

- Transfer source: address direction = forward, start address of data = even, with Wait
 - Transfer destination: address direction = backward, start address of data = even, without Wait
 - \overline{TC} is input when the "m"th byte ($m = \text{even}$) of the "n"th block is in transfer.
- $$\text{①} + (n - 1) (\text{②} + \text{③}) + \text{④} + \text{⑤} = 1 + (n - 1)\{5(3 + 4) + 3\} + m/2 + 1 = 38n + m/2 - 36 \text{ cycles}$$

(3) Array chain transfer mode and Link array chain transfer mode

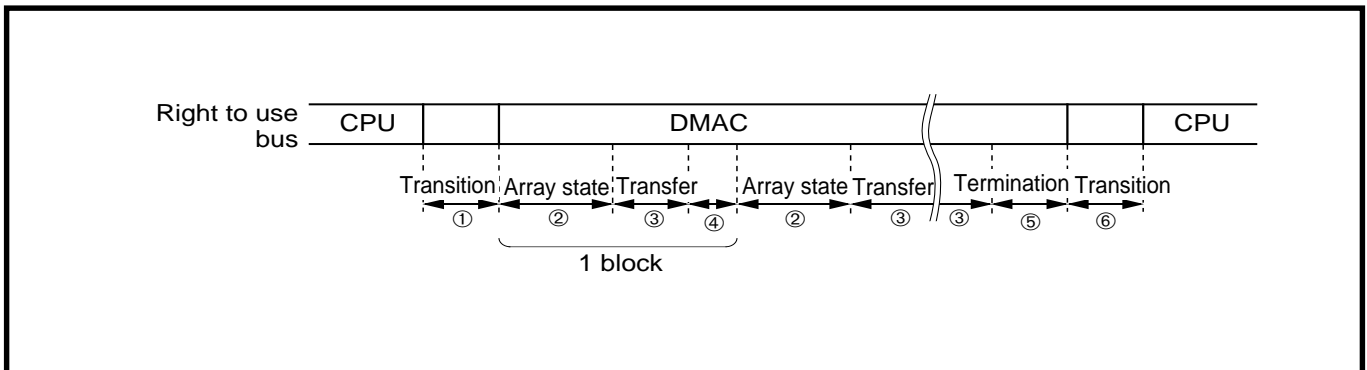

Fig 13.9.6 Array chain transfer mode and Link array chain transfer mode

- ① Transition of the right to use bus from CPU to DMAC: 1 cycle
- ② Array state:
The number of transfer parameters × the number of reads of a transfer parameter × the number of bus cycles for a read + 1 cycle (Refer to “Table 13.9.1.”)
- ③ DMA transfer per an entire batch of data:
 - In 2-bus cycle transfer... (Read cycle + Write cycle*¹) × the number of transfers*²
 - *1: Add a value which satisfies the read/write conditions. Refer to “Table 13.4.1.”
 - *2: When the transfer unit is 16 bits, the number of transfers = the number of transfer bytes/2
When the transfer unit is 8 bits, the number of transfers = the number of transfer bytes
 - In 1-bus cycle transfer... Refer to “Table 13.4.5.”
- ④ Last processing of each block: 3 cycles
- ⑤ Terminate processing: 3 cycles
- ⑥ Transition of the right to use bus from DMAC to CPU: 1 cycle

[Example]

Array chain transfer mode, external data bus width = 16 bits, 2-bus cycle transfer, transfer unit = 16 bits, the number of transfer blocks = 3, and under the following conditions:

- Transfer source: address direction = forward, without Wait
- Transfer destination: address direction = backward, without Wait
- First block: transfer source's data start address = even, transfer destination's data start address = even, the number of transfer bytes = 10 bytes
- Second block: transfer source's data start address = even, transfer destination's data start address = odd, the number of transfer bytes = 12 bytes
- Third block: transfer source's data start address = odd, transfer destination's data start address = odd, the number of transfer bytes = 14 bytes

$$\textcircled{1} + \textcircled{2} + \textcircled{3} + \textcircled{4} + \textcircled{2} + \textcircled{3} + \textcircled{4} + \textcircled{2} + \textcircled{3} + \textcircled{5} + \textcircled{6}$$

$$= 1 + 19 + 5(2 + 4) + 3 + 19 + 6(2 + 3) + 3 + 19 + 7(4 + 3) + 3 + 1 = 177 \text{ cycles}$$

DRAM CONTROLLER

14.2 Block description

14.2.2 Refresh timer

The refresh timer is an 8-bit timer with a reload register and is used to generate refresh requests for DRAM data. Assuming that the set value of the refresh timer = "n," the refresh timer counts f_{16} (n + 1) times. Figure 14.2.4 shows the structure of the refresh timer, and the following formula gives the value to be written to the refresh timer.

$$n = \{m [\mu\text{s}] \times \frac{f(X_{IN})}{16}\} - 1$$

n: a set value of the refresh timer (n = 01₁₆–FF₁₆)

m: a refresh interval

Examples of "m": an average of 15.625 μs for 512 refresh cycles at 8-ms intervals
an average of 125 μs for 512 refresh cycles at 64-ms intervals

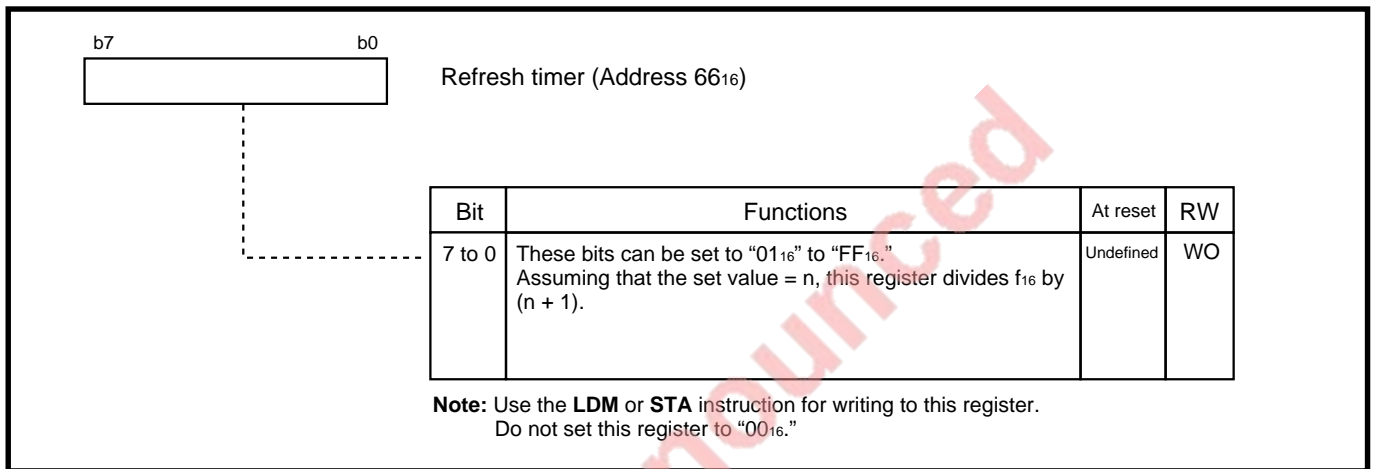

Fig. 14.2.4 Structure of refresh timer

DRAM CONTROLLER

14.2 Block description

14.2.3 Address comparator

The address comparator examines whether the address to be accessed is within the DRAM area. When this address is within DRAM area, control signals are sent to the $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ generating circuit and the address multiplexer.

14.2.4 $\overline{\text{RAS}}$ and $\overline{\text{CAS}}$ generating circuit

The $\overline{\text{RAS}}$ signal (a timing signal to latch a row address) and the $\overline{\text{CAS}}$ signal (a timing signal to latch a column address) are generated by a control signal from the address comparator.

14.2.5 Address multiplexer

Address data is time-shared by the control signal from the address comparator and is output to the MA_0 – MA_9 pins. The time-sharing method depends on the external bus width. Table 14.2.2 lists the time-sharing method for the address at DRAM access. When the 8-bit external bus width is selected, A_0 – A_{19} are time-shared and are output; when the 16-bit external bus width is selected, A_1 – A_{20} are time-shared and are output.

Table 14.2.2 Time-sharing method for address at DRAM access

Pin name		A_0/MA_0	A_1/MA_1	A_2/MA_2	A_3/MA_3	A_4/MA_4	A_5/MA_5	A_6/MA_6	A_7/MA_7	$\text{P10}_6/\text{MA}_8$	$\text{P10}_7/\text{MA}_9$	
Output signal	8-bit external bus width	Row address	A_0	A_1	A_2	A_3	A_4	A_5	A_6	A_7	A_{16}	A_{18}
		Column address	A_8	A_9	A_{10}	A_{11}	A_{12}	A_{13}	A_{14}	A_{15}	A_{17}	A_{19}
	16-bit external bus width	Row address	A_{16}	A_1	A_2	A_3	A_4	A_5	A_6	A_7	A_{18}	A_{20}
		Column address	A_8	A_9	A_{10}	A_{11}	A_{12}	A_{13}	A_{14}	A_{15}	A_{17}	A_{19}

14.3 Setting for DRAMC

Figure 14.3.1 shows an initial setting example for registers relevant to DRAMC.

Fig. 14.3.1 Initial setting example for registers relevant to DRAMC

DRAM CONTROLLER

14.4 DRAMC operation

14.4 DRAMC operation

14.4.1 Waveform example of DRAM control signals

Figure 14.4.1 shows a waveform example of the DRAM control signals. When DRAM is accessed, the bus cycle is always with “wait” (the low-level width of \overline{E} is equivalent to 2 cycles of ϕ). It is not affected by the wait bit, the wait bit of the transfer source, and the wait bit of the transfer destination.

(1) Read Cycle

In the read cycle, the \overline{CAS} signal falls with a delay of 0.5 cycle of ϕ after the \overline{RAS} signal has changed from “H” to “L.” The address bus signal changes from “row address” to “column address” within a period from a fall of \overline{RAS} until a fall of \overline{CAS} .

Pins $A_{16}/D_0-A_{23}/D_7$ and $A_8/D_8-A_{15}/D_{15}$ output addresses and input data in the same way as in reading external devices other than DRAM.

(2) Write Cycle

In the write cycle, the \overline{CAS} signal falls with a delay of 1 cycle of ϕ after the \overline{RAS} signal has changed from “H” to “L.” The address bus signal changes “row address” to “column address” within a period from a fall of \overline{RAS} until a fall of \overline{CAS} .

Pins $A_{16}/D_0-A_{23}/D_7$ and $A_8/D_8-A_{15}/D_{15}$ output addresses and data in the same way as in writing external devices other than DRAM.

(3) Refresh Cycle

In the refresh cycle, the \overline{RAS} signal falls with a delay of 0.5 cycle of ϕ after the \overline{CAS} signal has changed from “H” to “L.”

R/W is undefined.

One refresh request requires 5 cycle of ϕ , including the time for passing the right to use buses.

EOL announced

DRAM CONTROLLER

14.4 DRAMC operation

Fig. 14.4.1 Waveform example of DRAM control signals

DRAM CONTROLLER

14.4 DRAMC operation

14.4.2 Refresh request

- ① When the DRAM validity bit is set to "1," the refresh timer starts counting down. The count source is f_{16} .
- ② When the contents of the refresh timer reach "00₁₆," a refresh request occurs. The refresh timer reloads the contents of address 66₁₆ and continues counting.
- ③ Refresh requests are sampled as bus requests (DRAMC) by using the bus access controller. As soon as a refresh request is acknowledged by sampling, the following ④ is performed because DRAM refresh has the highest priority in using the bus. However, when the CPU or DMAC uses the bus, no bus request is sampled until the CPU or DMAC releases the bus. Therefore, in a period from when a refresh request occurs until DRAM refresh is performed, the delay listed in Table 14.4.1 occurs depending on the refresh request generating timing. Figures 14.4.2 and 14.4.3 show refresh delay time examples when CPU is operating and during DMA transfer. For a bus request, refer to "13.2.1 Bus access control circuit."
- ④ When the refresh request is accepted, the right to use the bus is passed to DRAM refresh (1 cycle of ϕ). Both of the output levels of ST1 and ST0 are "L." (The bus status is indicated as [0, 0].)
- ⑤ The RAS and the CAS signals are output and the DRAM data is refreshed (refresh cycle: 3 cycles of ϕ).
- ⑥ The right to use the bus is passed to the CPU, DRAM or Hold (1 cycle of ϕ). The outputs of ST1 and ST0 change.

Note: In Stop or Wait mode, DRAM refresh is not performed because no refresh request occurs.

Table 14.4.1 Delay time from when refresh request occurs until DRAM refresh is performed

Source of using bus		Delay time (unit: ϕ cycle)		
		Minimum	Maximum (no Wait)	Maximum (with Wait)
CPU		1.5	4.5	6.5
DMAC	Transfer (a unit of 1 transfer)	1.5	8.5	12.5
	Transfer (a unit of 1 transfer) + Complete cycle		11.5	15.5
	Array state		6.5	6.5
Hold		1.5	1.5	1.5

Note: The above is applied when Ready is not used. The delay time includes the time for passing the right to use buses to DRAM refresh (1 cycle).

DRAM CONTROLLER

14.4 DRAMC operation

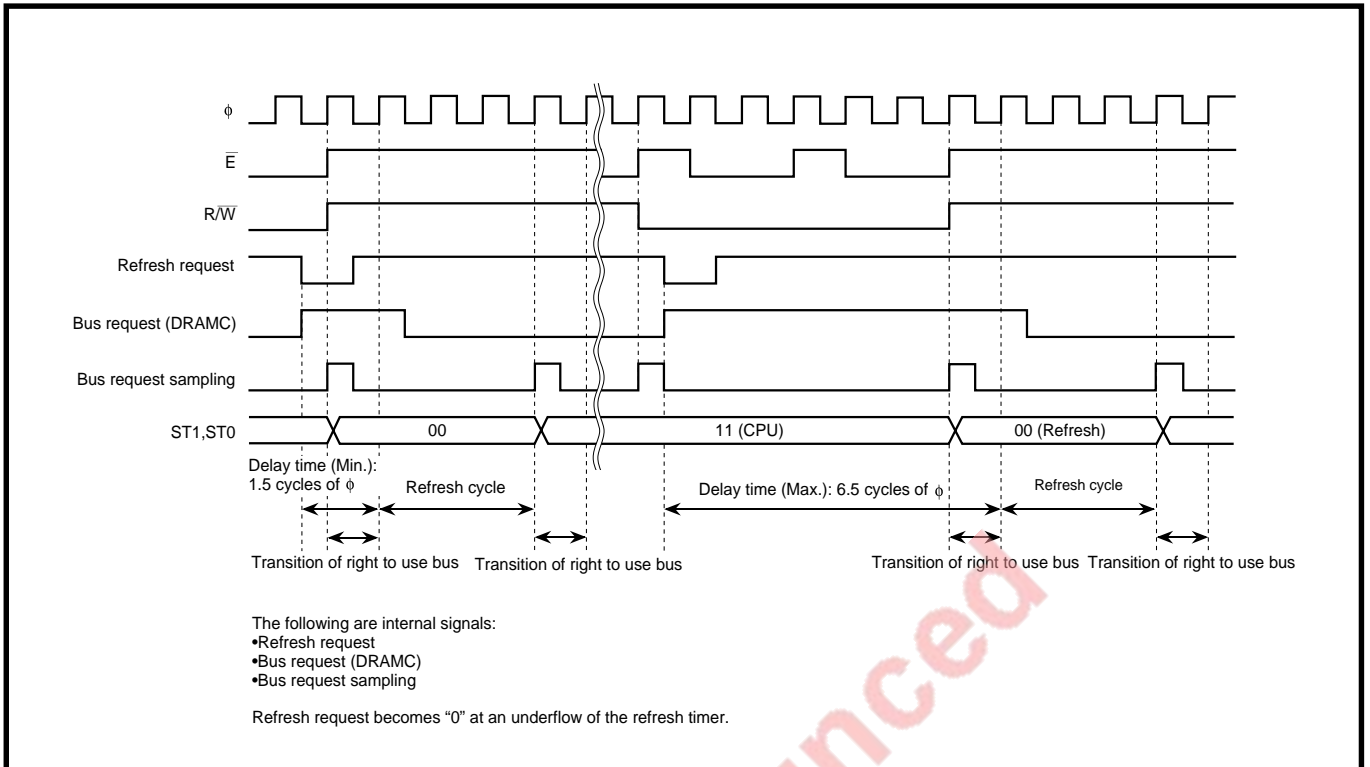

Fig. 14.4.2 Refresh delay time example when CPU is operating

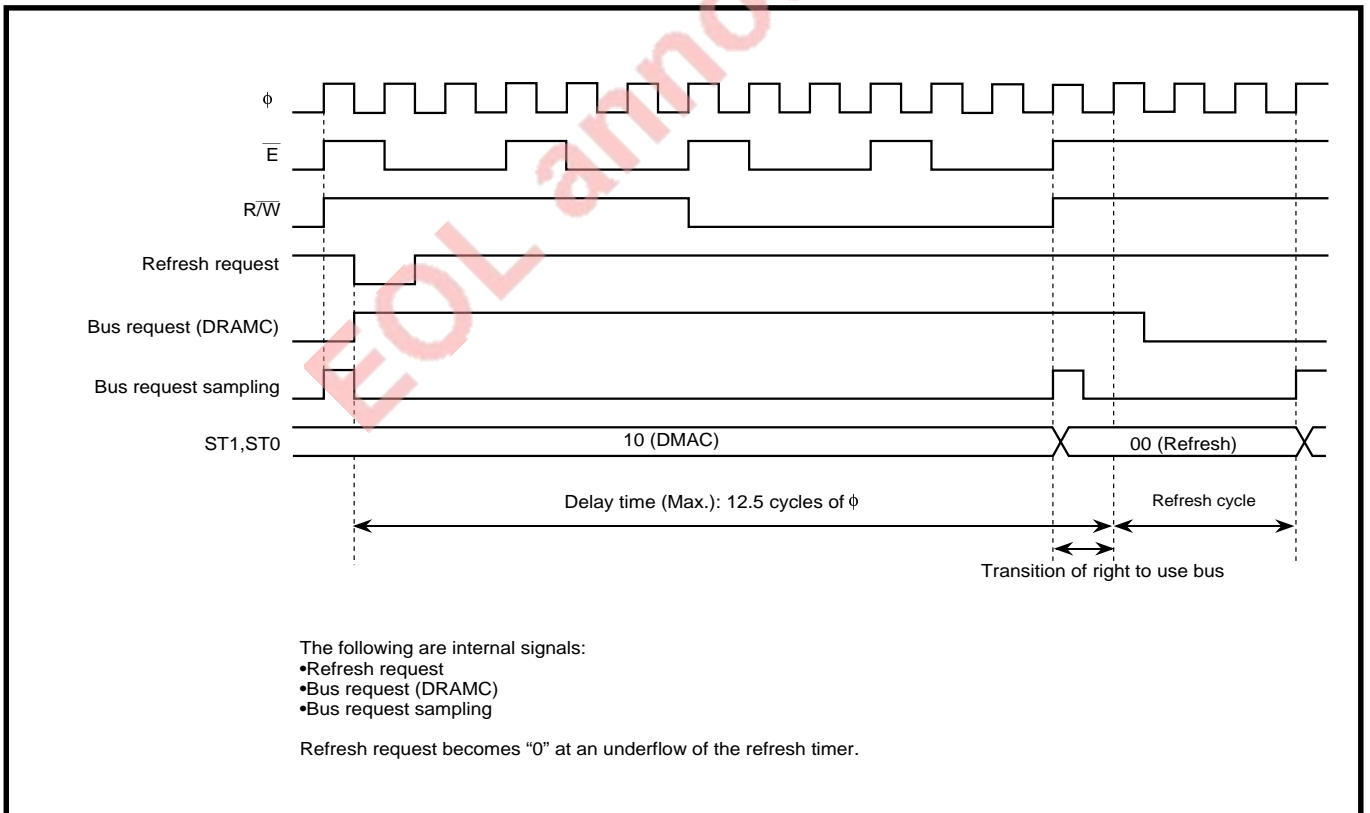

Fig. 14.4.3 Refresh delay time example during DMA transfer

DRAM CONTROLLER

14.5 Precautions for DRAMC

14.5 Precautions for DRAMC

1. Set the refresh timer (address 66₁₆) to any of 01₁₆–FF₁₆.
2. When a DRAM refresh request occurs during Hold state, a refresh cycle is activated regardless of the bus state. It is because a bus request is always sampled during Hold state. Therefore, in order to use the DRAMC together with the Hold function, an external circuit which is controlled depending on the states of ST0 and ST1 is required.
3. DRAM refresh is not performed in Stop or Wait mode.

WATCHDOG TIMER

15.1 Block description

15.2 Operation description

15.3 Precautions for Watchdog timer

EOL announced

WATCHDOG TIMER

15.1 Block description

Watchdog functions as follows:

- Detects a program runaway.
- Measures a certain time from when oscillation starts owing to terminating Stop mode.
(Refer to section “5.3 Stop mode.”)

15.1 Block description

Figure 15.1.1 shows the block diagram of Watchdog timer.

Fig. 15.1.1 Block diagram of Watchdog timer

WATCHDOG TIMER

15.1 Block description

15.1.1 Watchdog timer

Watchdog timer is a 12-bit counter where the count source which is selected with the watchdog timer frequency select bit (bit 0 at address 61_{16}) is counted down. A value “ FFF_{16} ” is automatically set in Watchdog timer in the cases listed below. An arbitrary value cannot be set to Watchdog timer.

- When dummy data is written to the watchdog timer register (Refer to “**Figure 15.1.2.**”)
- When the most significant bit of Watchdog timer becomes “0”
- When the **STP** instruction is executed (Refer to section “**5.3 Stop mode.**”)
- At reset

Fig. 15.1.2 Structure of watchdog timer register

15.1.2 Watchdog timer frequency select register

This is used to select a Watchdog timer's count source. Figure 15.1.3 shows the structure of the watchdog timer frequency select register.

Fig. 15.1.3 Structure of watchdog timer frequency select register

WATCHDOG TIMER

15.2 Operation description

15.2 Operation description

15.2.1 Basic operation

- ① Watchdog timer starts counting down from “FFF₁₆.”
- ② When the Watchdog timer’s most significant bit becomes “0” (counted 2048 times), a watchdog timer interrupt request occurs. (Refer to “**Table 15.2.1.**”)
- ③ When the interrupt request occurs at above ②, a value “FFF₁₆” is set to Watchdog timer.

The watchdog timer interrupt is a non-maskable interrupt. When the watchdog timer interrupt request is accepted, the processor interrupt priority level (IPL) is set to “111₂.”

Table 15.2.1 Occurrence interval of watchdog timer interrupt request

Watchdog timer frequency select bit	f(X _{IN}) = 25 MHz	
	Count source	Occurrence interval
0	f ₅₁₂	41.94 ms
1	f ₃₂	2.62 ms

EOL announced

WATCHDOG TIMER

15.2 Operation description

Write dummy data to the watchdog timer register (address 60_{16}) before the most significant bit of Watchdog timer becomes “0.” When Watchdog timer is used to detect a program runaway, a watchdog timer interrupt request occurs if writing to address 60_{16} is not performed owing to a program runaway and the most significant bit of Watchdog timer becomes “0.” This means that a program runaway has occurred. In order to reset the microcomputer when a program runaway is detected, write “1” to the software reset bit (bit 3 at address $5E_{16}$) in the watchdog timer interrupt routine.

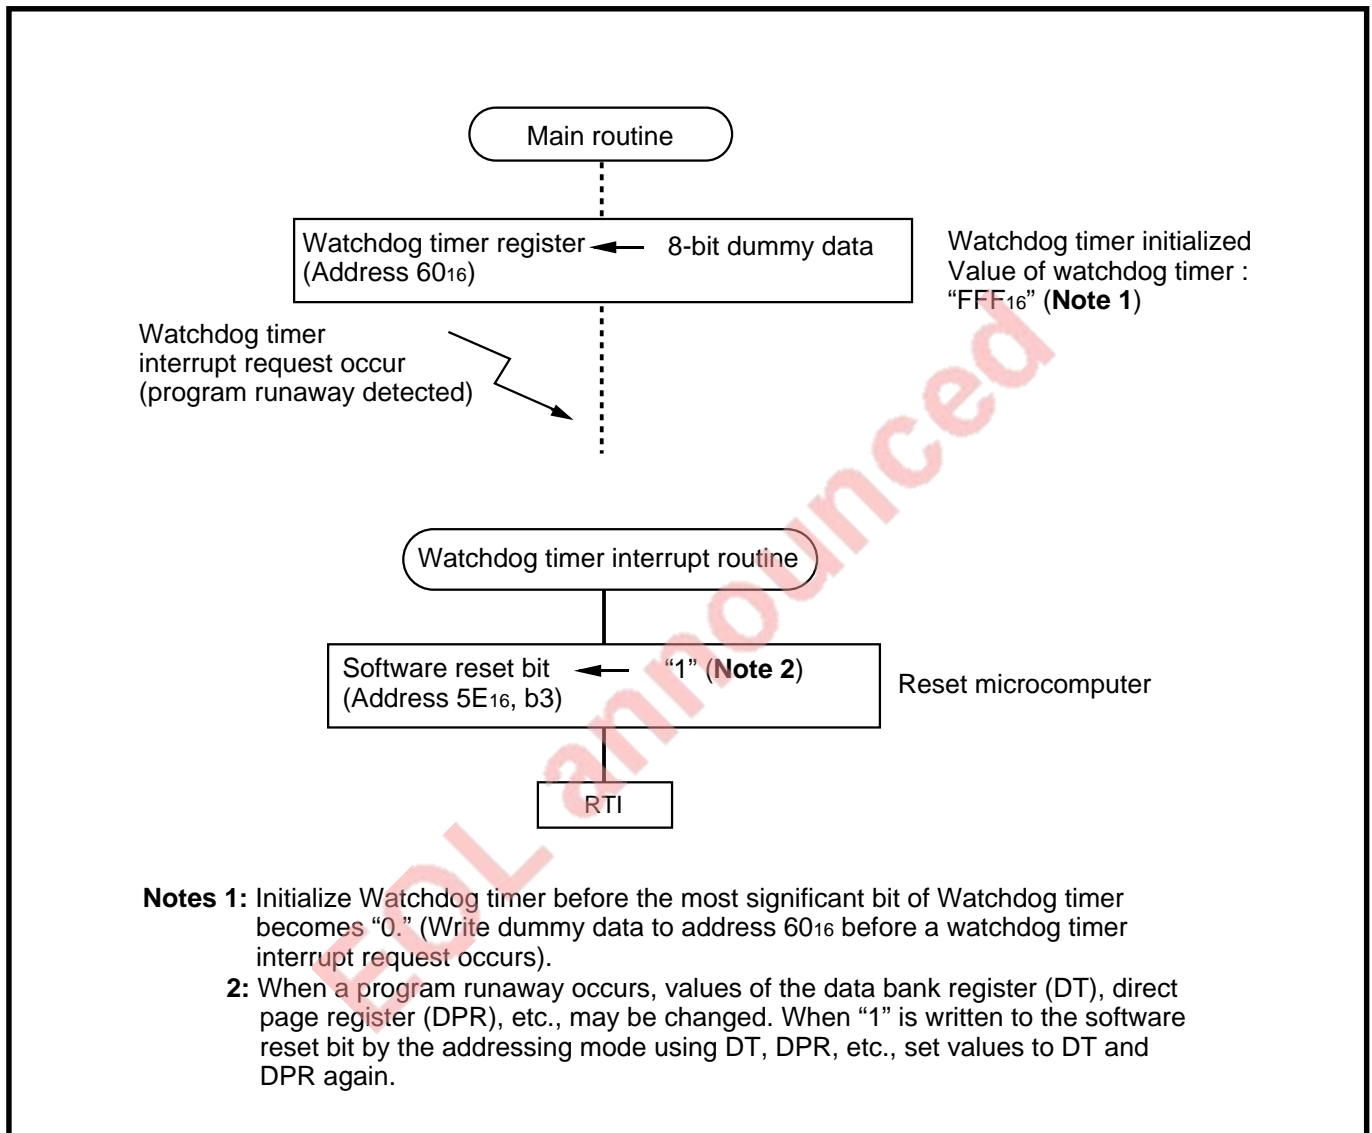

Fig. 15.2.1 Example of program runaway detection by Watchdog timer

WATCHDOG TIMER

15.2 Operation description

15.2.2 Stop period

Watchdog timer stops operation in the following period:

- ① Hold state (Refer to section “**3.4 Hold function.**”)
- ② During DMAC operation (Refer to “**CHAPTER 13. DMA CONTROLLER.**”)
- ③ During DRAM refresh (Refer to “**CHAPTER 14. DRAM CONTROLLER.**”)
- ④ Stop mode

When states ① to ③ are terminated, Watchdog timer restarts counting from the state before it stops operation. For Watchdog timer’s operation when state ④ is terminated, refer to section “**15.2.3 Operation in Stop mode.**”

15.2.3 Operation in Stop mode

In Stop mode, Watchdog timer stops operation. Immediately after Stop mode is terminated, Watchdog timer operates as follows. (Refer to section “**5.3 Stop mode.**”)

(1) When Stop mode is terminated by hardware reset

Supply of ϕ and ϕ_{CPU} starts immediately after Stop mode is terminated, and the microcomputer performs “operation after reset.” (Refer to “**CHAPTER 4. RESET.**”) The watchdog timer frequency select bit becomes “0,” and Watchdog timer starts counting of f_{512} from “ FFF_{16} .”

(2) When Stop mode is terminated by interrupt request occurrence

Immediately after Stop mode is terminated, Watchdog timer starts counting of f_{32} from “ FFF_{16} ” regardless of the contents of watchdog timer frequency select bit (bit 0 at address 61_{16}). Supply of ϕ and ϕ_{CPU} starts when Watchdog timer’s most significant bit becomes “0.” (At this time, a watchdog timer interrupt request does not occur.)

When supply of ϕ_{CPU} starts, the microcomputer executes the routine of the interrupt which is used to terminate Stop mode. Watchdog timer restarts counting of the count source (f_{32} or f_{512}), which was counted immediately before executing the **STP** instruction, from “ FFF_{16} .”

WATCHDOG TIMER

15.3 Precautions for Watchdog timer

15.3 Precautions for Watchdog timer

1. When dummy data is written to address 60_{16} with the 16-bit data length, writing to address 61_{16} is simultaneously performed. Accordingly, when the user does not want to change a value of the watchdog timer frequency select bit (bit 0 at address 61_{16}), write the previous value to the bit simultaneously with writing to address 60_{16} .
2. When the **STP** instruction is executed, Watchdog timer stops. (Refer to section “5.3 Stop mode.”)
3. Watchdog timer stops during DRAM refresh, hold state, and DMAC operation. (For Watchdog timer’s structure, refer to “Figure 15.1.1.”) Accordingly, when a bus request is changed in the period which is shorter than 1 cycle of the count source (**Note**), Watchdog timer’s count may gain. (Refer to “Figure 15.3.1.”)

Note: f_{32} or f_{512} , which is selected by the watchdog timer frequency select bit

Fig. 15.3.1 Count source for Watchdog timer

WATCHDOG TIMER

15.3 Precautions for Watchdog timer

MEMORANDUM

EOL announced

CHAPTER 16

APPLICATION

- 16.1 Memory connection
- 16.2 Examples of using DMA controller
- 16.3 Comparison of sample program execution rate

EOL announced

APPLICATION

16.1 Memory connection

This chapter describes application. Application shown here is just examples. The user shall modify them according to the actual application and test them.

16.1 Memory connection

This section shows examples for memory and I/O connection. Refer to “**CHAPTER 3. CONNECTION WITH EXTERNAL DEVICES**” for details about the functions and operations of used pins when connecting a memory or I/O. Refer to section “**Appendix 11. Electrical characteristics**” for timing requirements of the microcomputer.

16.1.1 Memory connection model

For the M37721, the level of the external data bus width select signal makes it possible to select the memory connection model from the four models listed in Table 16.1.1.

(1) Minimum model

This is a connection model of which external data bus width is 8 bits and access space is expanded up to 64 Kbytes. It is unnecessary to connect the address latch externally, so this model gives priority to cost and is most suitable when connecting the memory of which data bus width is 8 bits.

(2) Medium model A

This is a connection model of which external data bus width is 8 bits and access space is expanded up to 16 Mbytes. In this model, the high-order 8 bits of the external address bus (A_{16} to A_{23}) are multiplexed with the external data bus. Therefore, an n-bit ($n \leq 8$) address latch is required for latching n bits of the address in A_{16} to A_{23} .

(3) Medium model B

This is a connection model of which external data bus width is 16 bits and access space is expanded up to 64 Kbytes. This model gives priority to rate performance. In this model, the middle-order 8 bits of the external address bus (A_8 to A_{15}) are multiplexed with the external data bus. Therefore, an 8-bit address latch is required for latching A_8 to A_{15} .

(4) Maximum model

This is a connection model of which external data bus width is 16 bits and access space is expanded up to 16 Mbytes. In this model, the high- and middle-order 16 bits of the external address bus (A_8 to A_{23}) are multiplexed with the external data bus. Therefore, an 8-bit address latch for latching A_8 to A_{15} and an n-bit ($n \leq 8$) address latch for latching n bits of A_{16} to A_{23} are required.

Table 16.1.1 Memory connection model

Access space External data bus width	Maximum 64 Kbytes	Maximum 16 Mbytes
8-bit width; BYTE = "H"	<p>Memory connection model Minimum model</p>	<p>Memory connection model Medium model A</p>
16-bit width; BYTE = "L"	<p>Memory connection model Medium model B</p>	<p>Memory connection model Maximum model</p>

Notes 1: Refer to "CHAPTER 3. CONNECTION WITH EXTERNAL DEVICES" for details about the functions and operations of used pins when connecting a memory. Refer to section "Appendix 11. Electrical characteristics" for timing requirements.

2: Because the address bus can be expanded up to 24 bits when connecting a memory, strengthen the M37721's Vss and Vcc lines on the system. (Refer to section "Appendix 8. Countermeasure against noise.")

APPLICATION

16.1 Memory connection

16.1.2 How to calculate timing

Timings at which data is read or written when connecting a memory and precautions when connecting a memory are described below.

For timing requirements of the memory and detailed account except limits described below, also refer to the memory's Data book etc. When using bus buffers, various logical circuits, etc., be sure to consider the propagation delay time etc.

(1) Timing for reading data

When reading data, the external data bus is placed in a floating state, and data is read from the external memory. This floating state is maintained after the falling edge of the \bar{E} signal until an interval of $t_{pzx(E-DLZ/DHZ)}$ has passed after the rising edge of the \bar{E} signal. Satisfy $t_{su(DL/DH-E)}$ when inputting data read from the external memory.

The following are described below:

- Timing for reading data from the flash memory, SRAM, and DRAM
 - Calculation formulas for the external memory's access time, which are for $t_{su(DL/DH-E)}$ to be satisfied
- The memory output enable signal (\bar{OE}) is assumed to be generated from the \bar{E} signal.

● Timing for reading data from flash memory and SRAM

APPLICATION

16.1 Memory connection

(2) Timing for writing data

When writing data, the output data is stabilized when an interval of $t_{d(E-DLQ/DHQ)}$ has passed after the falling edge of the \bar{E} signal. This data is continuously output until when an interval of $t_{h(E-DLQ/DHQ)}$ has passed after the rising edge of the \bar{E} signal.

Data to be written to an external memory must satisfy the data setup time ($t_{su(D)}$) (for DRAM, the data hold time (t_{DH})) of the external memory.

The following are described below:

- Timing for writing data to flash memory, SRAM, and DRAM
- Calculation formulas which are for $t_{su(D)}$ and t_{DH} to be satisfied

● Timing for writing data to flash memory and SRAM

Fig. 16.1.5 Timing for writing data to flash memory and SRAM

$$\text{Data setup time : } t_{su(D)} \leq t_{w(EL)} - t_{d(E-DLQ/DHQ)}$$

Table 16.1.4 lists the calculation formulas and values for each parameter in Figure 16.1.5, Figure 16.1.6 shows the relationship between $t_{su(D)}$ and $f(X_{IN})$.

Table 16.1.4 Calculation formulas and Values for each parameter in Figure 16.1.5 (unit : ns)

APPLICATION

16.1 Memory connection

(3) Precautions on memory connection

As described in ① to ③ below, if specifications of the external memory do not match those of the M37721, some considerations must be incorporated into circuit design:

- ① When using an external memory that requires a long access time
- ② When data is output from an external memory before falling edge of the \bar{E} signal
- ③ When using an external memory that outputs data for more than $t_{pzx}(E-DLZ/DHZ)$ after rising edge of the \bar{E} signal

① When using external memory that requires long access time

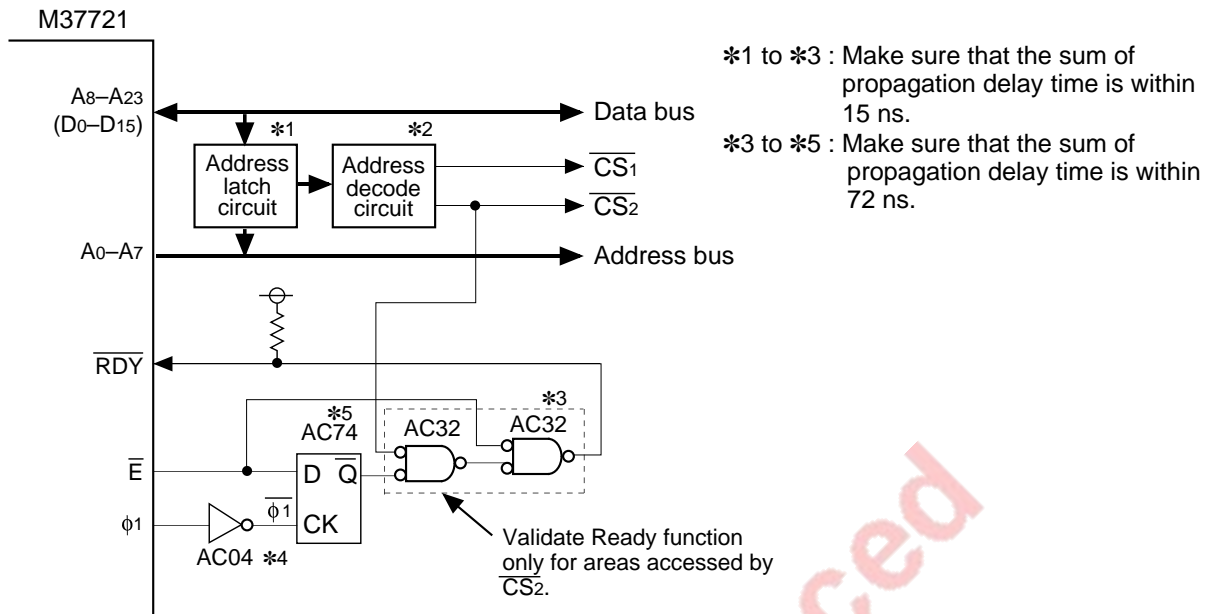

If the M37721's $t_{su}(DL/DH-E)$ cannot be satisfied because the external memory requires a long access time, try to carry out the following:

- Lower $f(X_{IN})$.
- Select "software Wait is inserted." (Refer to section "3.2 Software Wait.")
- Use Ready function. (Refer to section "3.3 Ready function.")

Figure 16.1.9 shows an example of using Ready function (no software Wait). Figure 16.1.10 shows an example of using Ready function (software Wait).

Ready function is valid for the internal areas, so that the circuits in Figures 16.1.9 and 16.1.10 use the chip select signal (\overline{CS}_2) to specify areas where Ready function is valid. In these cases, the \overline{CS}_2 signal is externally generated.

EOL announced

Circuit conditions : $f(X_{IN}) \leq 15.7 \text{ MHz}$, no software Wait

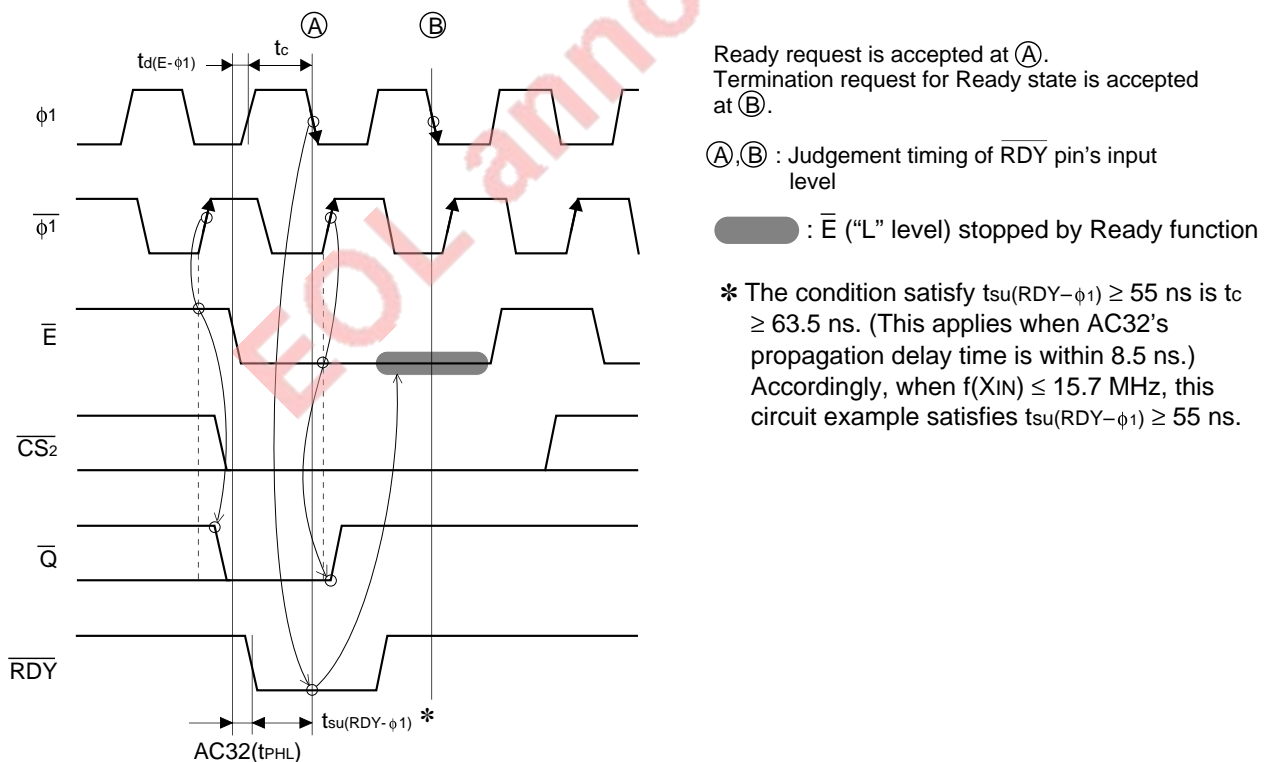

Fig. 16.1.9 Example of using Ready function (no software Wait)

APPLICATION

16.1 Memory connection

Fig. 16.1.10 Example of using Ready function (software Wait)

② When data is output from external memory before falling edge of \bar{E} signal

Because the external memory outputs data before the falling edge of the \bar{E} signal, there is a possibility that the tail of address collides with the head of data. In such a case, generate the external memory read signal (\overline{OE}) by using \bar{E} . (Refer to “Figure 16.1.11.”)

Fig. 16.1.11 Example of making data output timing delayed

③ When using external memory that outputs data for more than $t_{pzx(E-DLZ/DHZ)}$ after rising edge of \bar{E} signal

Because the external memory outputs data for more than $t_{pzx(E-DLZ/DHZ)}$ after the rising edge of the \bar{E} signal, there is a possibility that the tail of data collides with the head of address. In such a case, try to carry out the following:

- Cut the tail of data output from the memory by using, for example, a bus buffer.
- Use the Mitsubishi's memory chips that can be connected without a bus buffer.

Figures 16.1.12 to 16.1.15 show examples of using bus buffers and the timing charts. Table 16.1.6 lists the Mitsubishi's memory chips that can be connected without a bus buffer. When using one of these memory chips, timing parameters t_{DF} and $t_{dis(OE)}$ listed below are guaranteed. Accordingly, no bus buffer is necessary for the system where the external memory's read signal (\overline{OE}) goes high within $t_{pzx(E-DLZ/DHZ)} - t_{DF}$ (or $t_{dis(OE)}$) [ns] after the rising edge of the \bar{E} signal.

Table 16.1.6 Mitsubishi's memory chips that can be connected without bus buffers

Memory	Type	$t_{DF}/t_{dis(OE)}$ (Maximum)
Flash memory	M5M28F101AP, FP, J, VP, RV-85, -10	15 ns (Guaranteed as kit.)
	M5M28F102AFP, J, VP-85, -10	
SRAM	M5M5256DP, FP, KP, VP, RV-45LL, -45XL, -55LL, -55XL, -70LL, -70XL	(Note)
	M5M5278DP, J-12	6 ns
	M5M5278DP, FP, J-15, -15L	7 ns
	M5M5278DP, FP, J-20, -20L	8 ns

Note: t_{DF} or $t_{dis(OE)}$ listed above is guaranteed when these memory chips are connected with the M37721. When the user wants specifications of these memory chips, add a comment " $t_{DF}/t_{dis(OE)} = 15$ ns, microcomputer and kit."

16.1.4 Example of I/O expansion

(1) Example of port expansion circuit using M66010FP

Figure 16.1.36 shows an example of a port expansion circuit using the M66010FP. Make sure that the frequency of Serial I/O transfer clock must be 1.923 MHz or less.

About Serial I/O control in this expansion example is described below.

In this example, 8-bit data transmission/reception is performed 3 times by using UART0, so that 24-bit port expansion is realized. Setting of UART0 is described below:

- Clock synchronous serial I/O mode: Transmission/Reception enable state
- Internal clock is selected. Transfer clock frequency is 1.66 MHz.
- LSB first

The control procedure is described below:

- ① Output "L" level from port P4₅. (Expanded I/O ports of the M66010FP enter a floating state by this signal.)
- ② Output "H" level from port P4₅.
- ③ Output "L" level from port P4₄.
- ④ Transmit/Receive 24-bit data by using UART0.
- ⑤ Output "H" level from port P4₄.

Figure 16.1.37 shows the serial transfer timing between the M37721 and the M66010FP.

16.2 Examples of using DMA controller

16.2.1 Example of Centronics interface configuration

The following is an example of Centronics interface configured by using DMA0, Timers A2 and A3.

(1) Specifications

- Octal latch's contents are transferred to the data buffer (RAM) by using DMA0. The trigger is the STB signal. (Refer to "**Figure 16.2.1.**")
- "L" level width of the $\overline{\text{ACK}}$ signal is generated by using Timer A2; one-shot pulse mode; the trigger is the rising edge of the $\overline{\text{DMAACK0}}$ signal. (Refer to "**Figure 16.2.2.**")
- Timer A3 generates the time from when the $\overline{\text{ACK}}$ signal rises until the BUSY signal falls; one-shot pulse mode; the trigger is the rising edge of the $\overline{\text{DMAACK0}}$ signal. (Refer to "**Figure 16.2.2.**")
- P4₃ is used for BUSY signal generation. When outputting "H" level, the next transfer can wait. In that case, the contents of the preceding transfer are hold in the octal latch.
- When the data buffer is filled (in other words, DMA transfer is completed), a DMA interrupt occurs.

16.2.2 Example of stepping motor control

The following is an example where the slow-up or slow-down control for the stepping motor is performed by using DMA1, DMA2, and RTP0.

(1) Specifications

- DMA1 transfers the stepping motor's phase output data from the phase output data table to the RTP0 pulse output data register. (Refer to "Figure 16.2.6" and "Table 16.2.1.")
- DMA2 transfers the step time for slow up or slow down from the timer A0 set value data table to the timer A0 register. (Refer to "Figure 16.2.6.")
After slow up or slow down is completed, a DMA2 interrupt occurs.
- Phase output is performed by RTP0; pulse output mode 0 (Refer to "Figures 16.2.6 and 16.2.7.")
- After slow up or slow down is completed, the motor operates with the definite rate.

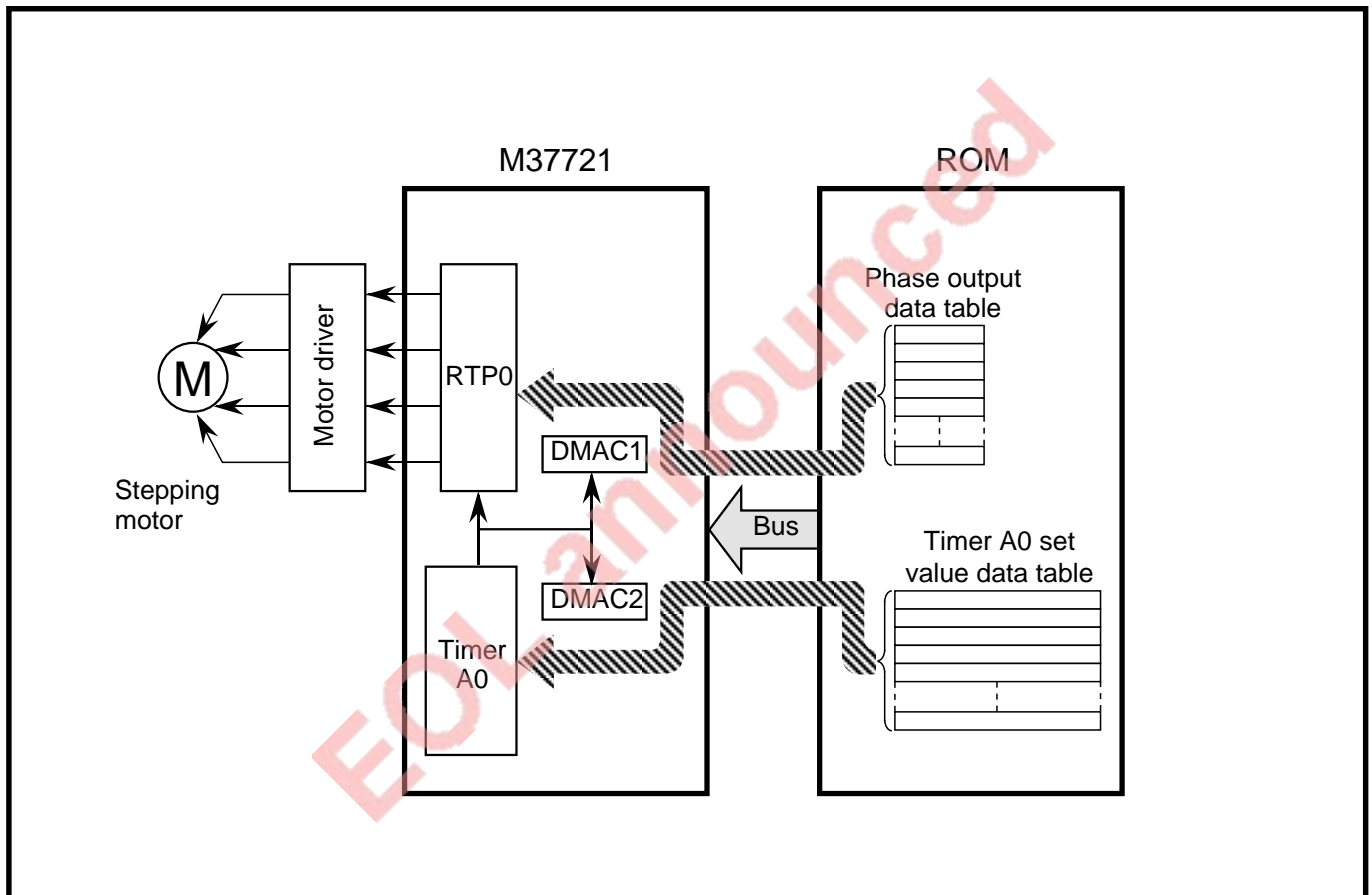

Fig. 16.2.6 Example of stepping motor control

16.2.3 Example of dynamic lighting for LED

The following is an example of dynamic lighting for LED by using DMA3 and Timer B0.

(1) Specifications

- The eight 7-segment LEDs are lighted up; port P6 outputs the segment data; port P7 outputs the digit data. (Refer to “Figure 16.2.11.”)
- The display data and the segment data are transferred from the data buffer to the port P6 and P7 registers by DMA3.
- Digit switch interval is generated by Timer B0.
- 16 bytes of RAM are used as the data buffer. 1-digit display data consists of 2 bytes; the digit data is placed in the high-order byte; the segment data is placed in the low-order byte. (Refer to “Table 16.2.2.”)

When the digit data and segment data are “0,” the LED is lighted up (ON): when they are “1,” the light goes out (OFF).

Assuming that the segment pattern is generated by another processing.

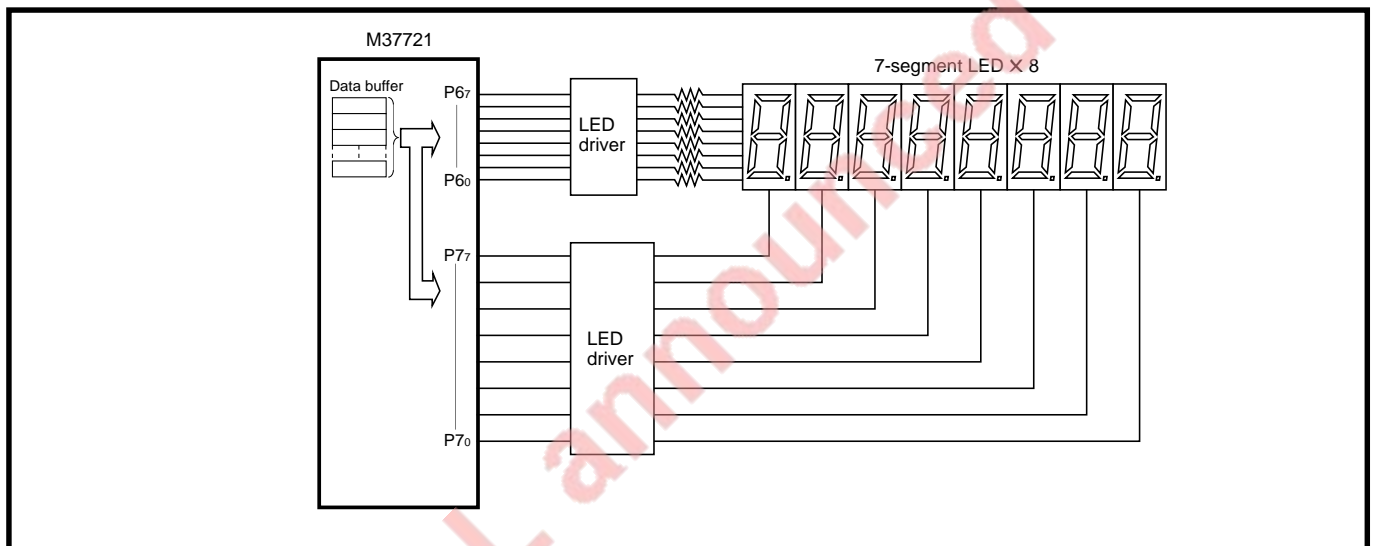

Fig. 16.2.11 Example of dynamic lighting for LED

Table 16.2.2 Data buffer

Data buffer	
Digit data	Segment pattern
00000001	Segment pattern of the contents to be displayed in each digit

APPLICATION

16.3 Comparison of sample program execution rate

16.3 Comparison of sample program execution rate

Sample program execution rates are compared in this paragraph.

The execution time ratio depends on the program or the usage conditions.

16.3.1 Differences depending on data bus width and software Wait

Internal areas are always accessed with data bus of which width is 16 bits and no software Wait. In the external areas, the external data bus width and software Wait are selectable. Table 16.3.1 lists the sample program (Refer to “**Figure 16.3.1.**”) execution time ratio depending on these selection and usable memory areas.

Table 16.3.1 Sample program execution time ratio (external data bus width and software Wait)

Memory area		External data bus width (unit : bit)	Software Wait	Sample program execution time ratio	
RAM	ROM			Sample A	Sample B
Internal	External	16	None	1.00	1.00
			Inserted	1.17	1.10
		8	None	1.19	1.08
			Inserted	1.67	1.46
External	Internal	16	None	1.00	1.00
			Inserted	1.25	1.17
		8	None	1.19	1.13
			Inserted	1.78	1.65
Calculated value *				0.92	0.90

Calculated value * : The value is calculated from the shortest execution cycle number of each instruction described in “**7700 Family Software Manual.**”

16.3 Comparison of sample program execution rate

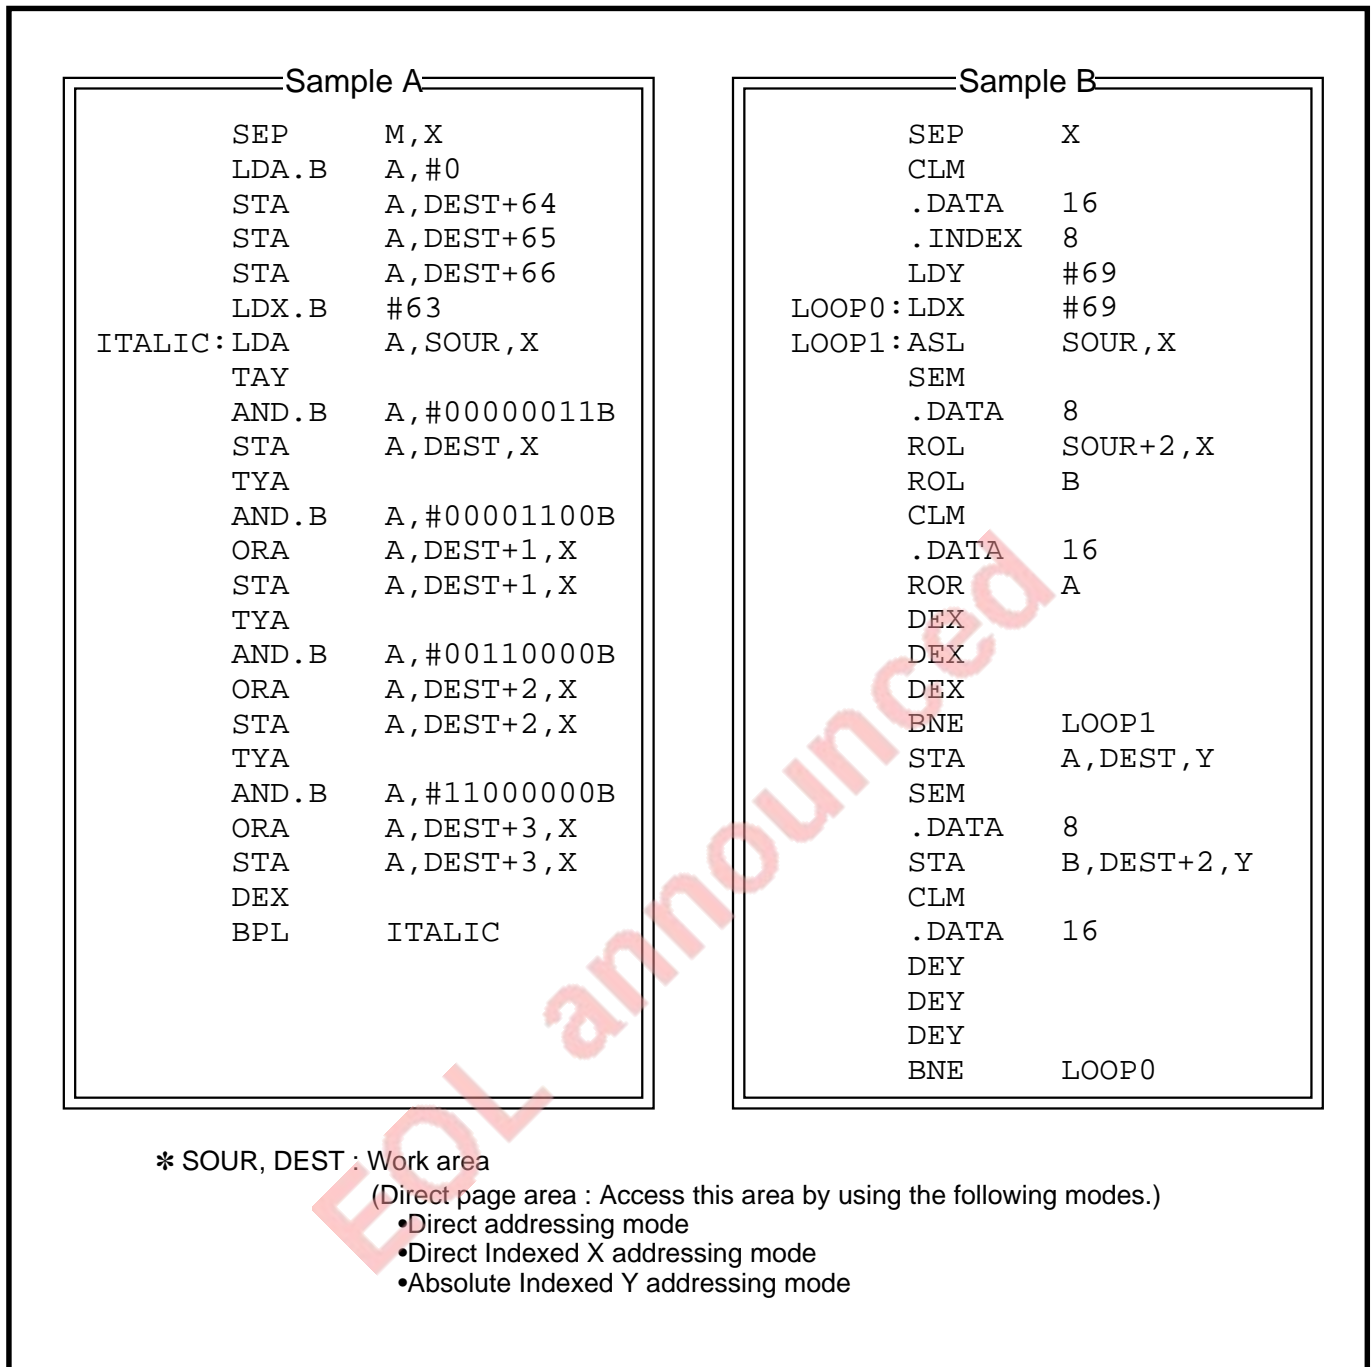

Fig. 16.3.1 Sample program list

APPLICATION

16.3 Comparison of sample program execution rate

16.3.2 Comparison between software Wait ($f(X_{IN}) = 20 \text{ MHz}$) and software Wait + Ready ($f(X_{IN}) = 25 \text{ MHz}$)

Figure 16.3.3 shows the execution time ratio when sample programs in Figure 16.3.1 are executed on the two conditions in Table 16.3.2. Figure 16.3.2 shows the memory assignment at execution rate comparison. The execution time ratio depends on the program or the usage conditions.

Table 16.3.2 Comparison conditions

Item	Condition ①	Condition ②
Processor mode	Microprocessor mode	Microprocessor mode
$f(X_{IN})$	20 MHz	25 MHz
External data bus width	16 bits	16 bits
Software Wait	Inserted	Inserted
Ready	Invalid	Valid only for external EPROM area
Program area	External EPROM	External EPROM
Work area	Internal or External SRAM	Internal or External SRAM

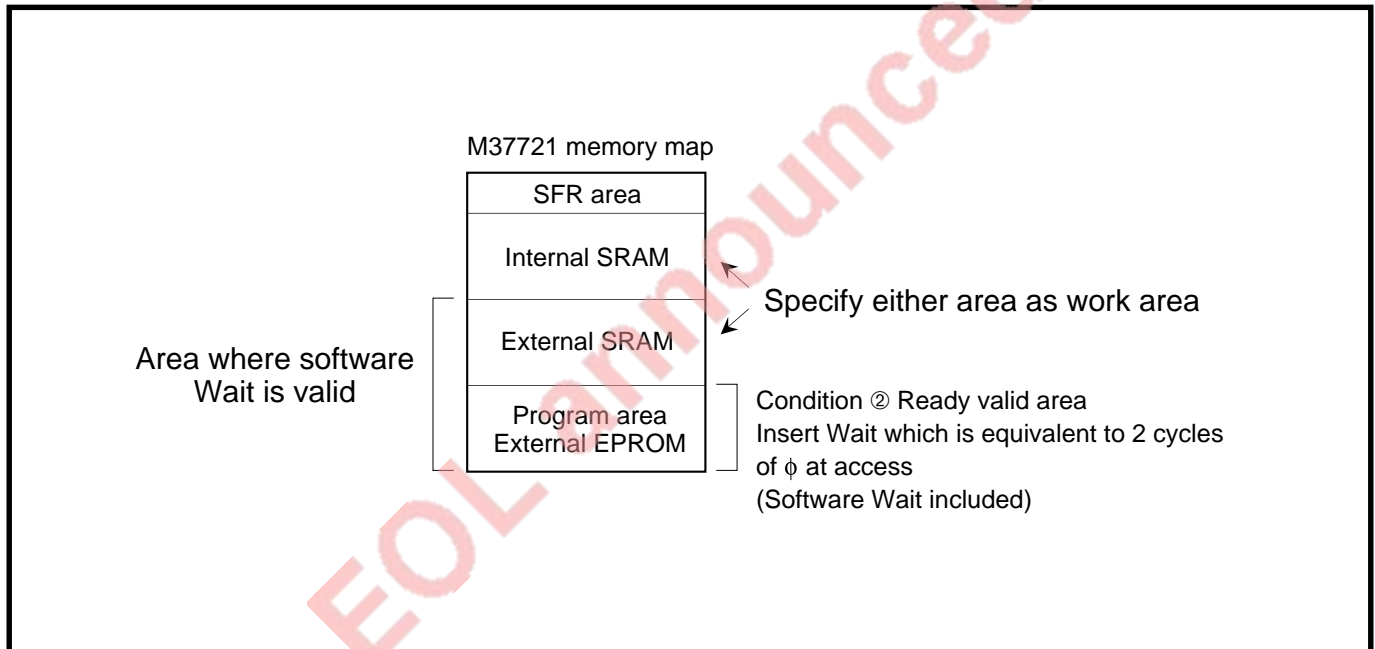

Fig. 16.3.2 Memory assignment at execution rate comparison

16.3 Comparison of sample program execution rate

Figure 16.3.3 shows that there is almost no difference between conditions ① and ② about the execution time. The bus buffers become unnecessary when using the specified memory. (Refer to “Table 16.1.6.”) Considering this, the case where software Wait is inserted with $f(X_{IN}) = 20$ MHz (condition ①) is superior in the cost performance.

Fig. 16.3.3 Execution time ratio

Access characteristics

RW : It is possible to read the bit state at reading. The written value becomes valid.

RO : It is possible to read the bit state at reading. The written value becomes invalid.

WO : The written value becomes valid. It is impossible to read the bit state.

□ : Nothing is assigned. It is impossible to read the bit state. The written value becomes invalid.

State immediately after reset

0 : "0" immediately after reset.

1 : "1" immediately after reset.

? : Undefined immediately after reset.

0 : Always "0" at reading.

1 : Always "1" at reading.

? : Always undefined at reading.

0 : "0" immediately after reset. Fix this bit to "0."

Address	Register name	Access characteristics		State immediately after reset

5F ₁₆	Processor mode register 1	RW		? (Note 4) ?	

Notes 1: The access characteristics at addresses 4A₁₆ to 4F₁₆ vary according to Timer A's operating mode. (Refer to "CHAPTER 8. TIMER A.")

2: The access characteristics at addresses 50₁₆ to 53₁₆ vary according to Timer B's operating mode. (Refer to "CHAPTER 9. TIMER B.")

3: The access characteristics for bit 5 at addresses 5B₁₆ and 5C₁₆ vary according to Timer B's operating mode. Bit 5 at address 5D₁₆ is invalid. (Refer to "CHAPTER 9. TIMER B.")

4: Bit 1 at address 5F₁₆ becomes "0" immediately after reset. For the M37721S1BFP, fix this bit to "0."

APPENDIX

Appendix 2. Memory assignment in SFR area

Access characteristics

RW : It is possible to read the bit state at reading. The written value becomes valid.

RO : It is possible to read the bit state at reading. The written value becomes invalid.

WO : The written value becomes valid. It is impossible to read the bit state.

□ : Nothing is assigned. It is impossible to read the bit state. The written value becomes invalid.

State immediately after reset

0 : "0" immediately after reset.

1 : "1" immediately after reset.

? : Undefined immediately after reset.

0 : Always "0" at reading.

1 : Always "1" at reading.

? : Always undefined at reading.

0 : "0" immediately after reset. Fix this bit to "0."

Appendix 3. Control registers

The control registers allocated in the SFR area are shown on the following pages. Below is the structure diagram for all registers.

- *1**
- Blank : Set to "0" or "1" according to the usage.
 - 0 : Set to "0" at writing.
 - 1 : Set to "1" at writing.
 - X : Invalid depending on the mode or state. It may be "0" or "1."
 - : Nothing is assigned.
- *2**
- 0 : "0" immediately after reset.
 - 1 : "1" immediately after reset.
 - Undefined : Undefined immediately after reset.
- *3**
- RW : It is possible to read the bit state at reading. The written value becomes valid.
 - RO : It is possible to read the bit state at reading. The written value becomes invalid. Accordingly, the written value may be "0" or "1."
 - WO : The written value becomes valid. It is impossible to read the bit state. The value is undefined at reading. However, when ["0" is at reading"] is indicated in the "Function" or "Note" column, the bit is always "0" at reading. (See *4 above.)
 - : It is impossible to read the bit state. The value is undefined at reading. However, when ["0" is at reading"] is indicated in the "Function" or "Note" column, the bit is always "0" at reading. (See *4 above.) The written value becomes invalid. Accordingly, the written value may be "0" or "1."
- *4**

APPENDIX

Appendix 3. Control registers

Port Pi register

Port Pi register (i = 4 to 10)
(Addresses A₁₆, B₁₆, E₁₆, F₁₆, 12₁₆, 13₁₆, 16₁₆)

Bit	Bit name	Functions	At reset	RW
0	Port Pi ₀ 's pin	Data is input from or output to a pin by reading from or writing to the corresponding bit. 0 : "L" level 1 : "H" level	Undefined	RW
1	Port Pi ₁ 's pin		Undefined	RW
2	Port Pi ₂ 's pin		Undefined	RW
3	Port Pi ₃ 's pin		Undefined	RW
4	Port Pi ₄ 's pin		Undefined	RW
5	Port Pi ₅ 's pin		Undefined	RW
6	Port Pi ₆ 's pin		Undefined	RW
7	Port Pi ₇ 's pin		Undefined	RW

Note: For bits 0 to 2 of the port P4 register, nothing is assigned and these bits are fixed to "0" at reading.

Port Pi direction register

Port Pi direction register (i = 4 to 10)
(Addresses C₁₆, D₁₆, 10₁₆, 11₁₆, 14₁₆, 15₁₆, 18₁₆)

Bit	Bit name	Functions	At reset	RW
0	Port Pi ₀ direction bit	0 : Input mode (The port functions as an input port) 1 : Output mode (The port functions as an output port)	0	RW
1	Port Pi ₁ direction bit		0	RW
2	Port Pi ₂ direction bit		0	RW
3	Port Pi ₃ direction bit		0	RW
4	Port Pi ₄ direction bit		0	RW
5	Port Pi ₅ direction bit		0	RW
6	Port Pi ₆ direction bit		0	RW
7	Port Pi ₇ direction bit		0	RW

Note: For bits 0 to 2 of the port P4 direction register, nothing is assigned and these bits are fixed to "0" at reading.

Pulse output data register 0

Pulse output data register 0 (Address 1A₁₆)

Bit	Bit name	Functions	At reset	RW
0	RTP0 ₀ pulse output data bit	0 : "L" level output 1 : "H" level output	Undefined	WO
1	RTP0 ₁ pulse output data bit		Undefined	WO
2	RTP0 ₂ pulse output data bit (Valid in pulse mode 0)		Undefined	WO
3	RTP0 ₃ pulse output data bit (Valid in pulse mode 0)		Undefined	WO
7 to 4	Nothing is assigned.		Undefined	—

Note: Use the LDM or STA instruction for writing to this register

Pulse output data register 1

Pulse output data register 1 (Address 1C₁₆)

Bit	Bit name	Functions	At reset	RW
0, 1	Nothing is assigned.		Undefined	—
2	RTP0 ₂ pulse output data bit (Valid in pulse mode 1)	0 : "L" level output 1 : "H" level output	Undefined	WO
3	RTP0 ₃ pulse output data bit (Valid in pulse mode 1)		Undefined	WO
4	RTP1 ₀ pulse output data bit		Undefined	WO
5	RTP1 ₁ pulse output data bit		Undefined	WO
6	RTP1 ₂ pulse output data bit		Undefined	WO
7	RTP1 ₃ pulse output data bit		Undefined	WO

Note: Use the LDM or STA instruction for writing to this register.

APPENDIX

Appendix 3. Control registers

A-D control register

A-D control register (Address 1E₁₆)

Bit	Bit name	Functions	At reset	RW
0	Analog input select bits (Valid in one-shot and repeat modes) (Note 1)	^{b2 b1 b0} 0 0 0 : AN ₀ selected 0 0 1 : AN ₁ selected 0 1 0 : AN ₂ selected 0 1 1 : AN ₃ selected 1 0 0 : AN ₄ selected 1 0 1 : AN ₅ selected 1 1 0 : AN ₆ selected 1 1 1 : AN ₇ selected (Note 2)	Undefined	RW
1			Undefined	RW
2			Undefined	RW
3	A-D operation mode select bit	^{b4 b3} 0 0 : One-shot mode 0 1 : Repeat mode 1 0 : Single sweep mode 1 1 : Repeat sweep mode	0	RW
4			0	RW
5	Trigger select bit	0 : Internal trigger 1 : External trigger	0	RW
6	A-D conversion start bit	0 : Stop A-D conversion 1 : Start A-D conversion	0	RW
7	A-D conversion frequency (Φ _{AD}) select bit	0 : f ₂ divided by 4 1 : f ₂ divided by 2	0	RW

- Notes**
- 1: These bits are invalid in the single sweep and repeat sweep mode. (They may be either "0" or "1.")
 - 2: When selecting an external trigger, the AN₇ pin cannot be used as an analog input pin.
 - 3: Writing to each bit (except bit 6) of the A-D control register must be performed while the A-D converter halts.

A-D sweep pin select register

A-D sweep pin select register (Address 1F₁₆)

Bit	Bit name	Functions	At reset	RW
0	A-D sweep pin select bits (Valid in single sweep and repeat sweep modes) (Note 1)	^{b1 b0} 0 0 : AN ₀ , AN ₁ (2 pins) 0 1 : AN ₀ to AN ₃ (4 pins) 1 0 : AN ₀ to AN ₅ (6 pins) 1 1 : AN ₀ to AN ₇ (8 pins) (Note 2)	1	RW
1			1	RW
7 to 2	Nothing is assigned.		Undefined	—

- Notes**
- 1: These bits are invalid in the one-shot and repeat modes. (They may be either "0" or "1.")
 - 2: When selecting an external trigger, the AN₇ pin cannot be used as an analog input pin.
 - 3: Writing to each bit of the A-D sweep pin select register must be performed while the A-D converter halts.

A-D register i

A-D register i (i = 0 to 7) (Addresses 20₁₆, 22₁₆, 24₁₆, 26₁₆, 28₁₆, 2A₁₆, 2C₁₆, 2E₁₆)

Bit	Functions	At reset	RW
7 to 0	Reads an A-D conversion result.	Undefined	RO

UARTi transmit/receive mode register

UART0 transmit/receive mode register (Address 30₁₆)
 UART1 transmit/receive mode register (Address 38₁₆)

Bit	Bit name	Functions	At reset	RW
0	Serial I/O mode select bits	b ₂ b ₁ b ₀ 0 0 0 : Serial I/O disabled (P8 functions as a programmable I/O port.) 0 0 1 : Clock synchronous serial I/O mode	0	RW
1		0 1 0 : Do not select. 0 1 1 : Do not select. 1 0 0 : UART mode (Transfer data length = 7 bits) 1 0 1 : UART mode (Transfer data length = 8 bits)	0	RW
2		1 1 0 : UART mode (Transfer data length = 9 bits) 1 1 1 : Do not select.	0	RW
3	Internal/External clock select bit	0 : Internal clock 1 : External clock	0	RW
4	Stop bit length select bit (Valid in UART mode) (Note)	0 : One stop bit 1 : Two stop bits	0	RW
5	Odd/Even parity select bit (Valid in UART mode when parity enable bit is "1") (Note)	0 : Odd parity 1 : Even parity	0	RW
6	Parity enable bit (Valid in UART mode) (Note)	0 : Parity disabled 1 : Parity enabled	0	RW
7	Sleep select bit (Valid in UART mode) (Note)	0 : Sleep mode terminated (Invalid) 1 : Sleep mode selected	0	RW

Note: Bits 4 to 6 are invalid in the clock synchronous serial I/O mode. (They may be either "0" or "1.") Additionally, fix bit 7 to "0."

UARTi baud rate register

UART0 baud rate register (Address 31₁₆)
 UART1 baud rate register (Address 39₁₆)

Bit	Functions	At reset	RW
7 to 0	Can be set to "00 ₁₆ " to "FF ₁₆ ." Assuming that the set value = n, BRG _i divides the count source frequency by (n + 1).	Undefined	WO

Note: Writing to this register must be performed while the transmission/reception halts. Use the **LDM** or **STA** instruction for writing to this register.

APPENDIX

Appendix 3. Control registers

UARTi transmit buffer register

UART0 transmit buffer register (Addresses 33₁₆, 32₁₆)
 UART1 transmit buffer register (Addresses 3B₁₆, 3A₁₆)

Bit	Functions	At reset	RW
8 to 0	Transmit data is set.	Undefined	WO
15 to 9	Nothing is assigned.	Undefined	—

Note: Use the **LDM** or **STA** instruction for writing to this register.

UARTi transmit/receive control register 0

UART0 transmit/receive control register 0 (Address 34₁₆)
 UART1 transmit/receive control register 0 (Address 3C₁₆)

Bit	Bit name	Functions	At reset	RW
0	BRG count source select bits	b1 b0 0 0 : f ₂ 0 1 : f ₁₆ 1 0 : f ₆₄ 1 1 : f ₅₁₂	0	RW
1			0	RW
2	CTS/RTS select bit	0 : CTS function selected 1 : RTS function selected	0	RW
3	Transmit register empty flag	0 : Data present in transmit register (During transmission) 1 : No data present in transmit register (Transmission completed)	1	RO
7 to 4	Nothing is assigned.		Undefined	—

UARTi transmit/receive control register 1

UART0 transmit/receive control register 1 (Address 35₁₆)
 UART1 transmit/receive control register 1 (Address 3D₁₆)

Bit	Bit name	Functions	At reset	RW
0	Transmit enable bit	0 : Transmission disabled 1 : Transmission enabled	0	RW
1	Transmit buffer empty flag	0 : Data present in transmit buffer register 1 : No data present in transmit buffer register	1	RO
2	Receive enable bit	0 : Reception disabled 1 : Reception enabled	0	RW
3	Receive complete flag	0 : No data present in receive buffer register 1 : Data present in receive buffer register	0	RO
4	Overrun error flag (Note 1)	0 : No overrun error 1 : Overrun error detected	0	RO
5	Framing error flag (Notes 1, 2) (Valid in UART mode)	0 : No framing error 1 : Framing error detected	0	RO
6	Parity error flag (Notes 1, 2) (Valid in UART mode)	0 : No parity error 1 : Parity error detected	0	RO
7	Error sum flag (Notes 1, 2) (Valid in UART mode)	0 : No error 1 : Error detected	0	RO

Notes 1: Bit 4 is cleared to "0" when the receive enable bit is cleared to "0" or when the serial I/O mode select bits (bits 2 to 0 at addresses 30₁₆, 38₁₆) are cleared to "000₂."
 Bits 5 and 6 are cleared to "0" when one of the following is performed:
 • Clearing the receive enable bit to "0"
 • Reading the low-order byte of the UARTi receive buffer register (addresses 36₁₆, 3E₁₆)
 out
 • Clearing the serial I/O mode select bits (bits 2 to 0 at addresses 30₁₆, 38₁₆) to "000₂"
 Bit 7 is cleared to "0" when all of bits 4 to 6 become "0."
2: Bits 5 to 7 are invalid in the clock synchronous serial I/O mode.

UARTi receive buffer register

UART0 receive buffer register (Addresses 37₁₆, 36₁₆)
 UART1 receive buffer register (Addresses 3F₁₆, 3E₁₆)

Bit	Functions	At reset	RW
8 to 0	Receive data is read out from here.	Undefined	RO
15 to 9	Nothing is assigned. The value is "0" at reading.	0	—

APPENDIX

Appendix 3. Control registers

Count start register

Count start register (Address 40₁₆)

Bit	Bit name	Functions	At reset	RW
0	Timer A0 count start bit	0 : Stop counting 1 : Start counting	0	RW
1	Timer A1 count start bit		0	RW
2	Timer A2 count start bit		0	RW
3	Timer A3 count start bit		0	RW
4	Timer A4 count start bit		0	RW
5	Timer B0 count start bit		0	RW
6	Timer B1 count start bit		0	RW
7	Timer B2 count start bit		0	RW

One-shot start register

One-shot start register (Address 42₁₆)

Bit	Bit name	Functions	At reset	RW
0	Fix these bits to "0." The value is "0" at reading.		0	WO
1			0	WO
2	Timer A2 one-shot start bit	1 : Start outputting one-shot pulse (valid when internal trigger is selected.) The value is "0" at reading.	0	WO
3	Timer A3 one-shot start bit		0	WO
4	Timer A4 one-shot start bit		0	WO
7 to 5	Nothing is assigned.		Undefined	—

Up-down register

Up-down register (Address 44₁₆)

Bit	Bit name	Functions	At reset	RW
0	Fix these bits to "0."		0	RW
1			0	RW
2	Timer A2 up-down bit	0 : Countdown 1 : Countup	0	RW
3	Timer A3 up-down bit	This function is valid when the contents of the up-down register is selected as the up-down switching factor.	0	RW
4	Timer A4 up-down bit		0	RW
5	Timer A2 two-phase pulse signal processing select bit (Note)	0 : Two-phase pulse signal processing function disabled 1 : Two-phase pulse signal processing function enabled	0	WO
6	Timer A3 two-phase pulse signal processing select bit (Note)		0	WO
7	Timer A4 two-phase pulse signal processing select bit (Note)	When not using the two-phase pulse signal processing function, set the bit to "0." The value is "0" at reading.	0	WO

Note: Use the LDM or STA instruction for writing to bits 5 to 7.

APPENDIX

Appendix 3. Control registers

Timer Ai register

Timer A0 register (Addresses 47₁₆, 46₁₆)
 Timer A1 register (Addresses 49₁₆, 48₁₆)
 Timer A2 register (Addresses 4B₁₆, 4A₁₆)
 Timer A3 register (Addresses 4D₁₆, 4C₁₆)
 Timer A4 register (Addresses 4F₁₆, 4E₁₆)

Bit	Functions	At reset	RW
15 to 0	These bits have different functions according to the operating mode.	Undefined	RW (Note 1)

Notes 1: The access characteristics for the timer A2 register, timer A3 register, and timer A4 register differ according to Timer A's operating mode.

2: Read from or write to this register in a unit of 16 bits.

Timer Ai mode register

Timer Ai mode register (i = 0 to 4) (Addresses 56₁₆ to 5A₁₆)

Bit	Bit name	Functions	At reset	RW
0	Operating mode select bits	b1 b0 0 0 : Timer mode 0 1 : Event counter mode 1 0 : One-shot pulse mode 1 1 : Pulse width modulation (PWM) mode	0	RW
1			0	RW
2	These bits have different functions according to the operating mode.		0	RW
3			0	RW
4			0	RW
5			0	RW
6			0	RW
7			0	RW

Timer Mode

Timer A0 register (Addresses 47₁₆, 46₁₆)
 Timer A1 register (Addresses 49₁₆, 48₁₆)
 Timer A2 register (Addresses 4B₁₆, 4A₁₆)
 Timer A3 register (Addresses 4D₁₆, 4C₁₆)
 Timer A4 register (Addresses 4F₁₆, 4E₁₆)

Bit	Functions	At reset	RW
15 to 0	These bits can be set to "0000 ₁₆ " to "FFFF ₁₆ ." Assuming that the set value = n, the counter divides the count source frequency by (n + 1). When reading, the register indicates the counter value.	Undefined	RW

Note: Read from or write to this register in a unit of 16 bits.

Timer A0 mode register (Address 56₁₆)
 Timer A1 mode register (Address 57₁₆)

Bit	Bit name	Functions	At reset	RW
0	Fix these bits to "0."		0	RW
1			0	RW
2			0	RW
3			0	RW
4			0	RW
5			0	RW
6	Count source select bits	b7 b6 0 0 : f ₂ 0 1 : f ₁₆ 1 0 : f ₆₄ 1 1 : f ₅₁₂	0	RW
7			0	RW

Timer A_j mode register (j = 2 to 4) (Addresses 58₁₆ to 5A₁₆)

Bit	Bit name	Functions	At reset	RW
0	Operating mode select bits	b1 b0 0 0 : Timer mode	0	RW
1			0	RW
2	Pulse output function select bit	0 : No pulse output (TA _{JOUT} pin functions as a programmable I/O port.) 1 : Pulse output (TA _{JOUT} pin functions as a pulse output pin.)	0	RW
3	Gate function select bits	b4 b3 0 0 : No gate function 0 1 : (TA _{JIN} pin functions as a programmable I/O port.) 1 0 : Counter counts only while TA _{JIN} pin's input signal is at "L" level. 1 1 : Counter counts only while TA _{JIN} pin's input signal is at "H" level.	0	RW
4			0	RW
5	Fix this bit to "0" in timer mode.		0	RW
6	Count source select bits	b7 b6 0 0 : f ₂ 0 1 : f ₁₆ 1 0 : f ₆₄ 1 1 : f ₅₁₂	0	RW
7			0	RW

APPENDIX

Appendix 3. Control registers

Event counter mode

Timer A2 register (Addresses 4B₁₆, 4A₁₆)
 Timer A3 register (Addresses 4D₁₆, 4C₁₆)
 Timer A4 register (Addresses 4F₁₆, 4E₁₆)

Bit	Functions	At reset	RW
15 to 0	These bits can be set to "0000 ₁₆ " to "FFFF ₁₆ ." Assuming that the set value = n, the counter divides the count source frequency by (n + 1) during countdown, or by (FFFF ₁₆ - n + 1) during countup. When reading, the register indicates the counter value.	Undefined	RW

Note: Read from or write to this register in a unit of 16 bits.

Timer A_j mode register (j = 2 to 4) (Addresses 58₁₆ to 5A₁₆)

Bit	Bit name	Functions	At reset	RW
0	Operating mode select bits	b ₁ b ₀ 0 1 : Event counter mode	0	RW
1			0	RW
2	Pulse output function select bit	0 : No pulse output (TA _j OUT pin functions as a programmable I/O port.) 1 : Pulse output (TA _j OUT pin functions as a pulse output pin.)	0	RW
3	Count polarity select bit	0 : Counts at falling edge of external signal 1 : Counts at rising edge of external signal	0	RW
4	Up-down switching factor select bit	0 : Contents of up-down register 1 : Input signal to TA _j OUT pin	0	RW
5	Fix this bit to "0" in event counter mode.		0	RW
6	These bits are invalid in event counter mode.		0	RW
7			0	RW

One-shot pulse mode

Timer A2 register (Addresses 4B₁₆, 4A₁₆)
 Timer A3 register (Addresses 4D₁₆, 4C₁₆)
 Timer A4 register (Addresses 4F₁₆, 4E₁₆)

Bit	Functions	At reset	RW
15 to 0	These bits can be set to "0001 ₁₆ " to "FFFF ₁₆ ." Assuming that the set value = n, the "H" level width of the one-shot pulse output from the TA _{jOUT} pin is expressed as follows : $\frac{n}{f_i}$.	Undefined	WO

f_i: Frequency of count source (f₂, f₁₆, f₆₄, or f₅₁₂)

Note: Use the **LDM** or **STA** instruction for writing to this register.
 Read from or write to this register in a unit of 16 bits.

Timer A_j mode register (j = 2 to 4) (Addresses 58₁₆ to 5A₁₆)

Bit	Bit name	Functions	At reset	RW
0	Operating mode select bits	b ₁ b ₀ 1 0 : One-shot pulse mode	0	RW
1			0	RW
2	Fix this bit to "1" in one-shot pulse mode.		0	RW
3	Trigger select bits	b ₄ b ₃ 0 0 : Writing "1" to one-shot start register 0 1 : (TA _{JIN} pin functions as a programmable I/O port.) 1 0 : Falling edge of TA _{JIN} pin's input signal 1 1 : Rising edge of TA _{JIN} pin's input signal	0	RW
4			0	RW
5	Fix this bit to "0" in one-shot pulse mode.		0	RW
6	Count source select bits	b ₇ b ₆ 0 0 : f ₂ 0 1 : f ₁₆ 1 0 : f ₆₄ 1 1 : f ₅₁₂	0	RW
7			0	RW

APPENDIX

Appendix 3. Control registers

Pulse width modulation (PWM) mode

<When operating as a 16-bit pulse width modulator>

Timer A2 register (Addresses 4B₁₆, 4A₁₆)
 Timer A3 register (Addresses 4D₁₆, 4C₁₆)
 Timer A4 register (Addresses 4F₁₆, 4E₁₆)

Bit	Functions	At reset	RW
15 to 0	These bits can be set to "0000 ₁₆ " to "FFFE ₁₆ ." Assuming that the set value = n, the "H" level width of the PWM pulse output from the TAJ _{OUT} pin is expressed as follows: $\frac{n}{f_i}$ (PWM pulse period = $\frac{n^{16} - 1}{f_i}$)	Undefined	WO

f_i: Frequency of count source (f₂, f₁₆, f₆₄, or f₅₁₂)

Note: Use the **LDM** or **STA** instruction for writing to this register.
 Read from or write to this register in a unit of 16 bits.

<When operating as an 8-bit pulse width modulator>

Timer A2 register (Addresses 4B₁₆, 4A₁₆)
 Timer A3 register (Addresses 4D₁₆, 4C₁₆)
 Timer A4 register (Addresses 4F₁₆, 4E₁₆)

Bit	Functions	At reset	RW
7 to 0	These bits can be set to "00 ₁₆ " to "FF ₁₆ ." Assuming that the set value = m, PWM pulse's period output from the TAJ _{OUT} pin is expressed as follows: $\frac{(m + 1)(2^8 - 1)}{f_i}$	Undefined	WO
15 to 8	These bits can be set to "00 ₁₆ " to "FE ₁₆ ." Assuming that the set value = n, the "H" level width of the PWM pulse output from the TAJ _{OUT} pin is expressed as follows: $\frac{n(m + 1)}{f_i}$	Undefined	WO

f_i: Frequency of count source (f₂, f₁₆, f₆₄, or f₅₁₂)

Note: Use the **LDM** or **STA** instruction for writing to this register.
 Read from or write to this register in a unit of 16 bits.

Timer A_j mode register (j = 2 to 4) (Addresses 58₁₆ to 5A₁₆)

Bit	Bit name	Functions	At reset	RW
0	Operating mode select bits	b ₁ b ₀ 1 1 : PWM mode	0	RW
1			0	RW
2	Fix this bit to "1" in PWM mode.		0	RW
3	Trigger select bits	b ₄ b ₃ 0 0 : Writing "1" to count start register 0 1 : (TAJ _{IN} pin functions as a programmable I/O port.)	0	RW
4		1 0 : Falling edge of TAJ _{IN} pin's input signal 1 1 : Rising edge of TAJ _{IN} pin's input signal	0	RW
5	16/8-bit PWM mode select bit	0 : 16-bit pulse width modulator 1 : 8-bit pulse width modulator	0	RW
6	Count source select bits	b ₇ b ₆ 0 0 : f ₂ 0 1 : f ₁₆	0	RW
7		1 0 : f ₆₄ 1 1 : f ₅₁₂	0	RW

Timer Bi register

Timer B0 register (Addresses 51₁₆, 50₁₆)
 Timer B1 register (Addresses 53₁₆, 52₁₆)
 Timer B2 register (Addresses 55₁₆, 54₁₆)

Bit	Functions	At reset	RW
15 to 0	These bits have different functions according to the operating mode.	Undefined	RW (Note 1)

Notes 1: The access characteristics for the timer B0 register and timer B1 register differ according to Timer B's operating mode.
2: Read from or write to this register in a unit of 16 bits.

Timer Bi mode register

Timer Bi mode register (i = 0 to 2) (Addresses 5B₁₆ to 5D₁₆)

Bit	Bit name	Functions	At reset	RW
0	Operating mode select bits	b1 b0 0 0 : Timer mode 0 1 : Event counter mode 1 0 : Pulse period/Pulse width measurement mode 1 1 : Do not select.	0	RW
1			0	RW
2	These bits have different functions according to the operating mode.		0	RW
3			0	RW
4	Nothing is assigned.		Undefined	—
5	These bits have different functions according to the operating mode.		Undefined	RO (Note)
6			0	RW
7			0	RW

Note: Bit 5 is invalid in the timer and event counter modes; its value is undefined at reading.

APPENDIX

Appendix 3. Control registers

Timer mode

Timer B0 register (Addresses 51₁₆, 50₁₆)
 Timer B1 register (Addresses 53₁₆, 52₁₆)
 Timer B2 register (Addresses 55₁₆, 54₁₆)

Bit	Functions	At reset	RW
15 to 0	These bits can be set to "0000 ₁₆ " to "FFFF ₁₆ ." Assuming that the set value = n, the counter divides the count source frequency by (n + 1). When reading, the register indicates the counter value.	Undefined	RW

Note: Read from or write to this register in a unit of 16 bits.

Timer Bi mode register (i = 0 to 2) (Addresses 5B₁₆ to 5D₁₆)

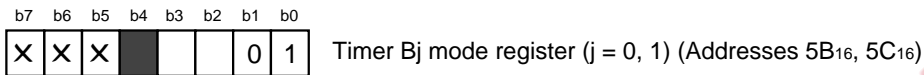

Bit	Bit name	Functions	At reset	RW
0	Operating mode select bits	b1 b0 0 0 : Timer mode	0	RW
1			0	RW
2	These bits are invalid in timer mode.		0	RW
3			0	RW
4	Nothing is assigned.		Undefined	—
5	This bit is invalid in timer mode; its value is undefined at reading.		Undefined	RO
6	Count source select bits	b7 b6 0 0 : f ₂ 0 1 : f ₁₆ 1 0 : f ₆₄ 1 1 : f ₅₁₂	0	RW
7			0	RW

Event counter mode

Bit	Functions	At reset	RW
15 to 0	These bits can be set to "0000 ₁₆ " to "FFFF ₁₆ ." Assuming that the set value = n, the counter divides the count source frequency by (n + 1). When reading, the register indicates the counter value.	Undefined	RW

Note: Read from or write to this register in a unit of 16 bits.

Bit	Bit name	Functions	At reset	RW
0	Operating mode select bits	b ₁ b ₀ 0 1 : Event counter mode	0	RW
1			0	RW
2	Count polarity select bits	b ₃ b ₂ 0 0 : Count at falling edge of external signal 0 1 : Count at rising edge of external signal 1 0 : Counts at both falling and rising edges of external signal 1 1 : Do not select.	0	RW
3			0	RW
4	Nothing is assigned.		Undefined	—
5	This bit is invalid in event counter mode; its value is undefined at reading.		Undefined	RO
6	These bits are invalid in event counter mode.		0	RW
7			0	RW

APPENDIX

Appendix 3. Control registers

Pulse period/pulse width measurement mode

Timer B0 register (Addresses 51₁₆, 50₁₆)
 Timer B1 register (Addresses 53₁₆, 52₁₆)

Bit	Functions	At reset	RW
15 to 0	The measurement result of pulse period or pulse width is read out.	Undefined	RO

Note: Read from this register in a unit of 16 bits.

Timer Bj mode register (j = 0, 1) (Addresses 5B₁₆, 5C₁₆)

Bit	Bit name	Functions	At reset	RW
0	Operating mode select bits	^{b1 b0} 1 0 : Pulse period/Pulse width measurement mode	0	RW
1			0	RW
2	Measurement mode select bits	^{b3 b2} 0 0 : Pulse period measurement (Interval between falling edges of measurement pulse) 0 1 : Pulse period measurement (Interval between rising edges of measurement pulse) 1 0 : Pulse width measurement (Interval from a falling edge to a rising edge, and from a rising edge to a falling edge of measurement pulse) 1 1 : Do not select.	0	RW
3			0	RW
4	Nothing is assigned.		Undefined	—
5	Timer Bj overflow flag (Note)	0 : No overflow 1 : Overflowed	Undefined	RO
6	Count source select bits	^{b7 b6} 0 0 : f ₂ 0 1 : f ₁₆ 1 0 : f ₆₄ 1 1 : f ₅₁₂	0	RW
7			0	RW

Note: The timer Bj overflow flag is cleared to “0” at the next count timing of the count source when a value is written to the timer Bj mode register with the count start bit = “1.”

Processor mode register 0

Processor mode register 0 (Address 5E16)

Bit	Bit name	Functions	At reset	RW
0	Fix this bit to "0."		0	RW
1	Nothing is assigned. The value is "1" at reading.		1	–
2	Wait bit	0 : Software Wait is inserted when accessing external area. 1 : No software Wait is inserted when accessing external area.	0	RW
3	Software reset bit	The microcomputer is reset by writing "1" to this bit. The value is "0" at reading.	0	WO
4	Interrupt priority detection time select bits	b5 b4 0 0 : 7 cycles of ϕ 0 1 : 4 cycles of ϕ 1 0 : 2 cycles of ϕ 1 1 : Do not select.	0	RW
5			0	RW
6	Fix this bit to "0."		0	RW
7	Stack bank select bit	0 : Bank 016 1 : Bank FF16	0	RW

Processor mode register 1

Processor mode register 1 (Address 5F16)

Bit	Bit name	Functions	At reset	RW
0	Nothing is assigned.		Undefined	–
1	Internal RAM area select bit (Notes 1, 2)	0 : 512 bytes (addresses 8016 to 27F16) 1 : 1024 bytes (addresses 8016 to 47F16)	0	RW
7 to 2	Nothing is assigned.		Undefined	–

Notes 1: For the M37721S1BFP, fix bit 1 to "0."

2: For the M37721S2BFP, set bit 1 before setting the stack pointer.

APPENDIX

Appendix 3. Control registers

Watchdog timer register

Watchdog timer register (Address 60₁₆)

Bit	Functions	At reset	RW
7 to 0	Initializes Watchdog timer. When dummy data is written to this register, Watchdog timer's value is initialized to "FFF ₁₆ ." (Dummy data: 00 ₁₆ to FF ₁₆)	Undefined	—

Watchdog timer frequency select register

Watchdog timer frequency select register (Address 61₁₆)

Bit	Bit name	Functions	At reset	RW
0	Watchdog timer frequency select bit	0 : f5 ₁₂ 1 : f3 ₂	0	RW
7 to 1	Nothing is assigned.		Undefined	—

EOL announced

Real-time output control register

Real-time output control register (Address 62₁₆)

Bit	Bit name	Functions	At reset	RW
0	Waveform output select bits	See the following Table.	0	RW
1			0	RW
2	Pulse output mode select bit	0 : Pulse mode 0 1 : Pulse mode 1	0	RW
7 to 3	Nothing is assigned. The value is "0" at reading.		Undefined	—

Note: When using the P6₀–P6₇ pins as the pulse output pins for real-time output, set the corresponding bits of the port P6 direction register (address 10₁₆) to "1."

b1 b0	00	01	10	11
When pulse mode 0 is selected	<ul style="list-style-type: none"> <input type="checkbox"/> P6₇/RTP1₃ <input type="checkbox"/> P6₆/RTP1₂ <input type="checkbox"/> P6₅/RTP1₁ <input type="checkbox"/> P6₄/RTP1₀ Port	<ul style="list-style-type: none"> <input type="checkbox"/> P6₇/RTP1₃ <input type="checkbox"/> P6₆/RTP1₂ <input type="checkbox"/> P6₅/RTP1₁ <input type="checkbox"/> P6₄/RTP1₀ Port	<ul style="list-style-type: none"> <input type="checkbox"/> P6₇/RTP1₃ <input type="checkbox"/> P6₆/RTP1₂ <input checked="" type="checkbox"/> P6₅/RTP1₁ <input type="checkbox"/> P6₄/RTP1₀ RTP	<ul style="list-style-type: none"> <input type="checkbox"/> P6₇/RTP1₃ <input type="checkbox"/> P6₆/RTP1₂ <input type="checkbox"/> P6₅/RTP1₁ <input type="checkbox"/> P6₄/RTP1₀ RTP
When pulse mode 1 is selected	<ul style="list-style-type: none"> <input type="checkbox"/> P6₃/RTP0₃ <input type="checkbox"/> P6₂/RTP0₂ <input type="checkbox"/> P6₁/RTP0₁ <input type="checkbox"/> P6₀/RTP0₀ Port	<ul style="list-style-type: none"> <input type="checkbox"/> P6₃/RTP0₃ <input type="checkbox"/> P6₂/RTP0₂ <input type="checkbox"/> P6₁/RTP0₁ <input type="checkbox"/> P6₀/RTP0₀ RTP	<ul style="list-style-type: none"> <input type="checkbox"/> P6₃/RTP0₃ <input type="checkbox"/> P6₂/RTP0₂ <input type="checkbox"/> P6₁/RTP0₁ <input type="checkbox"/> P6₀/RTP0₀ Port	<ul style="list-style-type: none"> <input type="checkbox"/> P6₃/RTP0₃ <input type="checkbox"/> P6₂/RTP0₂ <input type="checkbox"/> P6₁/RTP0₁ <input type="checkbox"/> P6₀/RTP0₀ RTP

Port : This functions as a programmable I/O port.
RTP : This functions as a pulse output pin.

APPENDIX

Appendix 3. Control registers

DRAM control register

DRAM control register (Address 64₁₆)

Bit	Bit name	Functions	At reset	RW
0	DRAM area select bits	b3 b2 b1 b0 0 0 0 0 : No DRAM area	0	RW
1		0 0 0 1 : F0000 ₁₆ –FFFFFF ₁₆ (1 Mbyte) 0 0 1 0 : E0000 ₁₆ –FFFFFF ₁₆ (2 Mbytes) 0 0 1 1 : D0000 ₁₆ –FFFFFF ₁₆ (3 Mbytes) 0 1 0 0 : C0000 ₁₆ –FFFFFF ₁₆ (4 Mbytes) 0 1 0 1 : B0000 ₁₆ –FFFFFF ₁₆ (5 Mbytes) 0 1 1 0 : A0000 ₁₆ –FFFFFF ₁₆ (6 Mbytes) 0 1 1 1 : 90000 ₁₆ –FFFFFF ₁₆ (7 Mbytes)		
2		1 0 0 0 : 80000 ₁₆ –FFFFFF ₁₆ (8 Mbytes) 1 0 0 1 : 70000 ₁₆ –FFFFFF ₁₆ (9 Mbytes) 1 0 1 0 : 60000 ₁₆ –FFFFFF ₁₆ (10 Mbytes) 1 0 1 1 : 50000 ₁₆ –FFFFFF ₁₆ (11 Mbytes)		
3		1 1 0 0 : 40000 ₁₆ –FFFFFF ₁₆ (12 Mbytes) 1 1 0 1 : 30000 ₁₆ –FFFFFF ₁₆ (13 Mbytes) 1 1 1 0 : 20000 ₁₆ –FFFFFF ₁₆ (14 Mbytes) 1 1 1 1 : 10000 ₁₆ –FFFFFF ₁₆ (15 Mbytes)		
6 to 4	Nothing is assigned. The value is "0" at reading.	0	–	
7	DRAM validity bit (Note)	0 : Invalid (P10 ₄ –P10 ₇ pins function as programmable input ports. A ₀ –A ₇ pins function as address output pins. Refresh timer stops counting.) 1 : Valid (P10 ₄ –P10 ₇ pins function as CAS, RAS, MA ₈ , and MA ₉ . A ₀ –A ₇ function as MA ₀ –MA ₇ . Refresh timer starts counting.)	0	RW

Note: Set the refresh timer (address 66₁₆) before setting this bit to "1."

Refresh timer

Refresh timer (Address 66₁₆)

Bit	Functions	At reset	RW
7 to 0	These bits can be set to "01 ₁₆ " to "FF ₁₆ ." Assuming that the set value = n, this register divides f ₁₆ by (n + 1).	Undefined	WO

Note: Use the **LDM** or **STA** instruction for writing to this register. Do not set this register to "00₁₆."

DMAC control register L

DMAC control register L (Address 6816)

Bit	Bit name	Functions	At reset	RW
0	Priority select bit	0 : Fixed 1 : Rotating	0	RW
1	$\overline{\text{TC}}$ pin validity bit	0 : Invalid (P10 ₃ pin functions as a programmable I/O port (CMOS).) 1 : Valid (P10 ₃ pin functions as $\overline{\text{TC}}$ pin (N-channel open-drain).)	0	RW
3, 2	Nothing is assigned.		Undefined	—
4	DMA0 request bit	0 : No request 1 : Requested (Note 1)	0	RW
5	DMA1 request bit		0	RW
6	DMA2 request bit		0	RW
7	DMA3 request bit		0	RW

- Notes**
- The state of bits 4 to 7 are not changed when writing "1" to these bits.
 - When writing to this register while any of DMA_i enable bits (bits 4 to 7 at address 69₁₆) is "1," set m flag to "1" and use the **LDM** or **STA** instruction. When DMA_i request bit (bits 4 to 7 at address 68₁₆) must not be changed, set DMA_i request bit to "1."
 - When writing to this register while all of DMA_i enable bits (bits 4 to 7 at address 69₁₆) are "0," m flag may be "0" or "1." Use the **LDM** or **STA** instruction for writing to this register. When DMA_i request bit (bits 4 to 7 at address 68₁₆) must not be changed, set DMA_i request bit to "1."

DMAC control register H

DMAC control register H (Address 6916)

Bit	Bit name	Functions	At reset	RW
0	Software DMA0 request bit	1 : DMA request (Valid when software DMA source is selected.) The value is "0" at reading.	0	WO
1	Software DMA1 request bit		0	WO
2	Software DMA2 request bit		0	WO
3	Software DMA3 request bit		0	WO
4	DMA0 enable bit	0 : Disabled 1 : Enabled	0	RW
5	DMA1 enable bit		0	RW
6	DMA2 enable bit		0	RW
7	DMA3 enable bit		0	RW

Note: When any of bits 4 to 7 is set to "1," use the **CLB** or **SEB** instruction for writing to this register.

APPENDIX

Appendix 3. Control registers

Interrupt control register

DMA0 to DMA3, A-D conversion, UART0 and 1 transmit, UART0 and 1 receive, timers A0 to A4, timers B0 to B2 interrupt control registers (Addresses 6C₁₆ to 7C₁₆)

Bit	Bit name	Functions	At reset	RW
0	Interrupt priority level select bits	b2 b1 b0 0 0 0 : Level 0 (Interrupt disabled) 0 0 1 : Level 1 0 1 0 : Level 2 0 1 1 : Level 3 1 0 0 : Level 4 1 0 1 : Level 5 1 1 0 : Level 6 1 1 1 : Level 7	0	RW
1			0	RW
2			0	RW
3			Interrupt request bit	0 : No interrupt requested 1 : Interrupt requested
7 to 4	Nothing is assigned.		Undefined	—

INT₀ to INT₂ interrupt control registers (Addresses 7D₁₆ to 7F₁₆)

Bit	Bit name	Functions	At reset	RW
0	Interrupt priority level select bits	b2 b1 b0 0 0 0 : Level 0 (Interrupt disabled) 0 0 1 : Level 1 0 1 0 : Level 2 0 1 1 : Level 3 1 0 0 : Level 4 1 0 1 : Level 5 1 1 0 : Level 6 1 1 1 : Level 7	0	RW
1			0	RW
2			0	RW
3			Interrupt request bit (Note)	0 : No interrupt requested 1 : Interrupt requested
4	Polarity select bit	0 : Interrupt request bit is set to "1" at "H" level when level sense is selected; this bit is set to "1" at falling edge when edge sense is selected. 1 : Interrupt request bit is set to "1" at "L" level when level sense is selected; this bit is set to "1" at rising edge when edge sense is selected.	0	RW
5	Level sense/Edge sense select bit	0 : Edge sense 1 : Level sense	0	RW
7, 6	Nothing is assigned.		Undefined	—

Note: The interrupt request bits of INT₀ to INT₂ interrupts are invalid when the level sense is selected.

Source address register i

Source address register 0 (Addresses 1FC2₁₆ to 1FC0₁₆)
 Source address register 1 (Addresses 1FD2₁₆ to 1FD0₁₆)
 Source address register 2 (Addresses 1FE2₁₆ to 1FE0₁₆)
 Source address register 3 (Addresses 1FF2₁₆ to 1FF0₁₆)

Bit	Functions	At reset	RW
23 to 0	These bits have different functions according to the operating mode.	Undefined	RW

Note: When writing to this register, write to all 24 bits.

Destination address register i

Destination address register 0 (Addresses 1FC6₁₆ to 1FC4₁₆)
 Destination address register 1 (Addresses 1FD6₁₆ to 1FD4₁₆)
 Destination address register 2 (Addresses 1FE6₁₆ to 1FE4₁₆)
 Destination address register 3 (Addresses 1FF6₁₆ to 1FF4₁₆)

Bit	Functions	At reset	RW
23 to 0	These bits have different functions according to the operating mode.	Undefined	RW

Note: When writing to this register, write to all 24 bits.

Transfer counter register i

Transfer counter register 0 (Addresses 1FCA₁₆ to 1FC8₁₆)
 Transfer counter register 1 (Addresses 1FDA₁₆ to 1FD8₁₆)
 Transfer counter register 2 (Addresses 1FEA₁₆ to 1FE8₁₆)
 Transfer counter register 3 (Addresses 1FFA₁₆ to 1FF8₁₆)

Bit	Functions	At reset	RW
23 to 0	These bits have different functions according to the operating mode.	Undefined	RW

Note: When writing to this register, write to all 24 bits.
 Do not write "00000₁₆" to this register.

APPENDIX

Appendix 3. Control registers

Single transfer mode

Source address register 0 (Addresses 1FC2₁₆ to 1FC0₁₆)
 Source address register 1 (Addresses 1FD2₁₆ to 1FD0₁₆)
 Source address register 2 (Addresses 1FE2₁₆ to 1FE0₁₆)
 Source address register 3 (Addresses 1FF2₁₆ to 1FF0₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the transfer start address of the source. These bits can be set to "000000 ₁₆ " to "FFFFFF ₁₆ ." [Read] The read value indicates the source address of data which is next transferred.	Undefined	RW

Note: When writing to this register, write to all 24 bits.

Destination address register 0 (Addresses 1FC6₁₆ to 1FC4₁₆)
 Destination address register 1 (Addresses 1FD6₁₆ to 1FD4₁₆)
 Destination address register 2 (Addresses 1FE6₁₆ to 1FE4₁₆)
 Destination address register 3 (Addresses 1FF6₁₆ to 1FF4₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the transfer start address of the destination. These bits can be set to "000000 ₁₆ " to "FFFFFF ₁₆ ." [Read] The read value indicates the destination address of data which is next transferred.	Undefined	RW

Note: When writing to this register, write to all 24 bits.

Transfer counter register 0 (Addresses 1FCA₁₆ to 1FC8₁₆)
 Transfer counter register 1 (Addresses 1FDA₁₆ to 1FD8₁₆)
 Transfer counter register 2 (Addresses 1FEA₁₆ to 1FE8₁₆)
 Transfer counter register 3 (Addresses 1FFA₁₆ to 1FF8₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the byte number of the transfer data. These bits can be set to "000001 ₁₆ " to "FFFFFF ₁₆ ." [Read] The read value indicates remaining byte number of the transfer data.	Undefined	RW

Note: When writing to this register, write to all 24 bits.
 Do not set this register to "000000₁₆."

Repeat transfer mode

Source address register 0 (Addresses 1FC2₁₆ to 1FC0₁₆)
 Source address register 1 (Addresses 1FD2₁₆ to 1FD0₁₆)
 Source address register 2 (Addresses 1FE2₁₆ to 1FE0₁₆)
 Source address register 3 (Addresses 1FF2₁₆ to 1FF0₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the transfer start address of the source. These bits can be set to "000000 ₁₆ " to "FFFFFF ₁₆ ." [Read] The read value indicates the source address of data which is next transferred.	Undefined	RW

Note: When writing to this register, write to all 24 bits.

Destination address register 0 (Addresses 1FC6₁₆ to 1FC4₁₆)
 Destination address register 1 (Addresses 1FD6₁₆ to 1FD4₁₆)
 Destination address register 2 (Addresses 1FE6₁₆ to 1FE4₁₆)
 Destination address register 3 (Addresses 1FF6₁₆ to 1FF4₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the transfer start address of the destination. These bits can be set to "000000 ₁₆ " to "FFFFFF ₁₆ ." [Read] The read value indicates the destination address of data which is next transferred.	Undefined	RW

Note: When writing to this register, write to all 24 bits.

Transfer counter register 0 (Addresses 1FCA₁₆ to 1FC8₁₆)
 Transfer counter register 1 (Addresses 1FDA₁₆ to 1FD8₁₆)
 Transfer counter register 2 (Addresses 1FEA₁₆ to 1FE8₁₆)
 Transfer counter register 3 (Addresses 1FFA₁₆ to 1FF8₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the byte number of the transfer data. These bits can be set to "000001 ₁₆ " to "FFFFFF ₁₆ ." [Read] The read value indicates the remaining byte number of the block which is being transferred.	Undefined	RW

Note: When writing to this register, write to all 24 bits.
 Do not write "000000₁₆" to this register.

APPENDIX

Appendix 3. Control registers

Array chain transfer mode

Source address register 0 (Addresses 1FC2₁₆ to 1FC0₁₆)
 Source address register 1 (Addresses 1FD2₁₆ to 1FD0₁₆)
 Source address register 2 (Addresses 1FE2₁₆ to 1FE0₁₆)
 Source address register 3 (Addresses 1FF2₁₆ to 1FF0₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the start address of transfer parameter memory. These bits can be set to "000000 ₁₆ " to "FFFFFF ₁₆ ." [Read] •After a value is written to this register and until transfer starts, the read value indicates the written value (the start address of the transfer parameter memory). •After transfer starts, the read value indicates the source address of data which is next transferred.	Undefined	RW

Note: When writing to this register, write to all 24 bits.

Destination address register 0 (Addresses 1FC6₁₆ to 1FC4₁₆)
 Destination address register 1 (Addresses 1FD6₁₆ to 1FD4₁₆)
 Destination address register 2 (Addresses 1FE6₁₆ to 1FE4₁₆)
 Destination address register 3 (Addresses 1FF6₁₆ to 1FF4₁₆)

Bit	Functions	At reset	RW
23 to 0	Need not to set. [Read] After transfer starts, the read value indicates the destination address of data which is next transferred.	Undefined	RW

Transfer counter register 0 (Addresses 1FCA₁₆ to 1FC8₁₆)
 Transfer counter register 1 (Addresses 1FDA₁₆ to 1FD8₁₆)
 Transfer counter register 2 (Addresses 1FEA₁₆ to 1FE8₁₆)
 Transfer counter register 3 (Addresses 1FFA₁₆ to 1FF8₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the number of transfer blocks. These bits can be set to "000001 ₁₆ " to "FFFFFF ₁₆ ." [Read] •After a value is written to this register and until transfer starts, the read value indicates the written value (the transfer block number). •After transfer starts, the read value indicates the remaining byte number of the block which is being transferred.	Undefined	RW

Note: When writing to this register, write to all 24 bits.
 Do not write "000000₁₆" to this register.

Link array chain transfer mode

Source address register 0 (Addresses 1FC2₁₆ to 1FC0₁₆)
 Source address register 1 (Addresses 1FD2₁₆ to 1FD0₁₆)
 Source address register 2 (Addresses 1FE2₁₆ to 1FE0₁₆)
 Source address register 3 (Addresses 1FF2₁₆ to 1FF0₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the start address of transfer parameter memory of block which is first transferred. These bits can be set to "000000 ₁₆ " to "FFFFFF ₁₆ ." [Read] •After a value is written to this register and until transfer starts, the read value indicates the written value (the start address of the transfer parameter memory of block which is first transferred). •After transfer starts, the read value indicates the source address of data which is next transferred.	Undefined	RW

Note: When writing to this register, write to all 24 bits.

Destination address register 0 (Addresses 1FC6₁₆ to 1FC4₁₆)
 Destination address register 1 (Addresses 1FD6₁₆ to 1FD4₁₆)
 Destination address register 2 (Addresses 1FE6₁₆ to 1FE4₁₆)
 Destination address register 3 (Addresses 1FF6₁₆ to 1FF4₁₆)

Bit	Functions	At reset	RW
23 to 0	Need not to set. [Read] After transfer starts, the read value indicates the destination address of data which is next transferred.	Undefined	RW

Transfer counter register 0 (Addresses 1FCA₁₆ to 1FC8₁₆)
 Transfer counter register 1 (Addresses 1FDA₁₆ to 1FD8₁₆)
 Transfer counter register 2 (Addresses 1FEA₁₆ to 1FE8₁₆)
 Transfer counter register 3 (Addresses 1FFA₁₆ to 1FF8₁₆)

Bit	Functions	At reset	RW
23 to 0	[Write] Set the dummy data. These bits can be set to "000001 ₁₆ " to "FFFFFF ₁₆ ." [Read] •After a value is written to this register and until transfer starts, the read value indicates the written value (dummy data). •After transfer starts, the read value indicates the remaining byte number of the block which is being transferred.	Undefined	RW

Note: When writing to this register, write to all 24 bits.
 Do not write "000000₁₆" to this register.

APPENDIX

Appendix 3. Control registers

DMAi mode register L

DMA0 mode register L (Address 1FCC₁₆)

DMA1 mode register L (Address 1FDC₁₆)

DMA2 mode register L (Address 1FEC₁₆)

DMA3 mode register L (Address 1FFC₁₆)

Bit	Bit name	Functions	At reset	RW
0	Number-of-unit-transfer-bits select bit (Note)	0 : 16 bits 1 : 8 bits	0	RW
1	Transfer method select bit	0 : 2-bus cycle transfer 1 : 1-bus cycle transfer	0	RW
2	Transfer mode select bit	0 : Burst transfer mode 1 : Cycle-steal transfer mode	0	RW
3	Fix this bit to "0."		0	RW
4	Transfer source address direction select bits	b5b4 0 0 : Fixed 0 1 : Forward 1 0 : Backward 1 1 : Do not select.	0	RW
5			0	RW
6	Transfer destination address direction select bits	b7b6 0 0 : Fixed 0 1 : Forward 1 0 : Backward 1 1 : Do not select.	0	RW
7			0	RW

Note: When the external data bus has a width of 8 bits and 1-bus cycle transfer is selected, set bit 0 to "1."

DMAi mode register H

DMA0 mode register H (Address 1FCD₁₆)

DMA1 mode register H (Address 1FDD₁₆)

DMA2 mode register H (Address 1FED₁₆)

DMA3 mode register H (Address 1FFD₁₆)

Bit	Bit name	Functions	At reset	RW
0	Transfer direction select bit (Used in 1-bus cycle transfer) (Note 1)	0 : From memory to I/O 1 : From I/O to memory	0	RW
1	I/O connection select bit (Valid in 1-bus cycle transfer)	Refer to "Fig.13.2.7."	0	RW
2	Fix these bits to "0."		0	RW
3			0	RW
4	Transfer source wait bit (Note 2)	0 : Wait 1 : No Wait	0	RW
5	Transfer destination wait bit (Note 2)		0	RW
6	Continuous transfer mode select bits	b7b6 0 0 : Single transfer 0 1 : Repeat transfer 1 0 : Array chain transfer 1 1 : Link array chain transfer	0	RW
7			0	RW

Notes 1: Set bit 0 to "0" in 2-bus cycle transfer.

2: Bits 4 and 5 are valid to the external and internal areas. However, DRAM area is always handled with "Wait" regardless of the contents of these bits. The wait bit (bit 2 at address 5E₁₆) is invalid in DMA transfer.

DMAi control register

DMA0 control register (Address 1FCE₁₆)

DMA1 control register (Address 1FDE₁₆)

DMA2 control register (Address 1FEE₁₆)

DMA3 control register (Address 1FFE₁₆)

Bit	Bit name	Functions	At reset	RW
0	DMA request source select bits (Note)	b3b2b1b0 0 0 0 0 : Do not select. 0 0 0 1 : External source (DMAREQ _i) 0 0 1 0 : Software DMA source 0 0 1 1 : Timer A0 0 1 0 0 : Timer A1 0 1 0 1 : Timer A2 0 1 1 0 : Timer A3 0 1 1 1 : Timer A4 1 0 0 0 : Timer B0 1 0 0 1 : Timer B1 1 0 1 0 : Timer B2 1 0 1 1 : UART0 receive 1 1 0 0 : UART0 transmit 1 1 0 1 : UART1 receive 1 1 1 0 : UART1 transmit 1 1 1 1 : A-D conversion	0	RW
1			0	RW
2			0	RW
3			0	RW
4	Edge sense/Level sense select bit (Used when external source and burst transfer mode are selected) (Note)	0 : Edge sense (Falling edge) 1 : Level sense ("L" level)	0	RW
5	DMAACK _i validity bit	0 : Invalid (The pin functions as a programmable I/O port.) 1 : Valid (The pin functions as DMAACK _i .)	0	RW
7, 6	Nothing is assigned.		Undefined	–

Note: When a certain source other than an external source is selected by bits 0 to 3 or when the cycle-steal transfer mode is selected, set bit 4 to "0."
Level sense can be selected only when both of the external source and the burst transfer mode are selected.

Appendix 5. Examples of handling unused pins

Appendix 5. Examples of handling unused pins

Examples of handling unused pins are described below. These descriptions are just examples. The user shall modify them according to the actual application and test them.

Table 1 Examples of handling unused pins

Pins	Handling example
P4 ₃ to P4 ₇ , P5 to P10	Connect these pins to the Vcc or Vss pin via resistors after these pins are set to the input mode, or leave these pins open after they are set to the output mode (Notes 1, 2).
BLE, BHE, ALE, ϕ_1 , ST0, ST1	Leave this pin open.
X _{OUT} (Note 3)	Leave this pin open.
HOLD, RDY	Connect these pins to the Vcc pin via resistors (These pins are pulled high.) (Note 2)
CNVss	Connect this pin to the Vcc pin or Vss pin.
AVcc	Connect this pin to the Vcc pin.
AVss, V _{REF}	Connect these pins to the Vss pin.

Notes 1: When leaving these pins open after they are set to the output mode, note the following: these pins function as input ports from reset until they are switched to the output mode by software. Therefore, voltage levels of these pins are undefined and the power source current may increase while these pins function as input ports. Accordingly, set these ports to the output mode immediately after reset. Software reliability can be enhanced when the contents of the above ports' direction registers are set periodically. This is because these contents may be changed by noise, a program runaway which occurs to noise, etc.

2: For unused pins, use the shortest possible wiring (within 20 mm from the microcomputer's pins).

3: This applies when a clock externally generated is input to the X_{IN} pin.

Fig. 2 Examples of handling unused pins

APPENDIX

Appendix 6. Machine instructions

The number of cycles shown in the table is described in the case of the fastest mode for each instruction. The number of cycles shown in the table is calculated for DPRL=0. The number of cycles in the addressing mode concerning the DPR when DPRL 0 must be incremented by 1.

The number of cycles shown in the table differs according to the bytes fetched into the instruction queue buffer, or according to whether the memory read/write address is odd or even. It also differs when the external region memory is accessed by BYTE="H."

Notes 1. The operation code at the upper row is used for accumulator A, and the operation at the lower row is used for accumulator B.

2. When setting flag m=0 to handle the data as 16-bit data in the immediate addressing mode, the number of bytes increments by 1.

3. The number of cycles increments by 2 when branching.

4. The operation code on the upper row is used for branching in the range of -128 to +127, and the operation code on the lower row is used for branching in the range of -32768 to +32767.

5. When handling 16-bit data with flag m=0, the byte in the table is incremented by 1.

6.

Type of register	A	B	X	Y	DPR	DT	PG	PS
Number of cycles	2	2	2	2	2	1	1	2

The number of cycles corresponding to the register to be pushed are added. The number of cycles when no pushing is done is 12. i_1 indicates the number of registers among A, B, X, Y, DPR, and PS to be saved, while i_2 indicates the number of registers among DT and PG to be saved.

7.

Type of register	A	B	X	Y	DPR	DT	PS
Number of cycles	3	3	3	3	4	3	3

The number of cycles corresponding to the register to be pulled are added. The number of cycles when no pulling is done is 14. i_1 indicates the number of registers among A, B, X, Y, DT, and PS to be restored, while $i_2=1$ when DPR is to be restored.

8. The number of cycles is the case when the number of bytes to be transferred is even. When the number of bytes to be transferred is odd, the number is calculated as;

$$7 + (i/2) \times 7 + 4$$

Note that, $(i/2)$ shows the integer part when i is divided by 2.

9. The number of cycles is the case when the number of bytes to be transferred is even. When the number of bytes to be transferred is odd, the number is calculated as;

$$9 + (i/2) \times 7 + 5$$

Note that, $(i/2)$ shows the integer part when i is divided by 2.

10. The number of cycles is the case in the 16-bit ÷ 8-bit operation. The number of cycles is incremented by 16 for 32-bit ÷ 16-bit operation.

11. The number of cycles is the case in the 8-bit × 8-bit operation. The number of cycles is incremented by 8 for 16-bit × 16-bit operation.

12. When setting flag x=0 to handle the data as 16-bit data in the immediate addressing mode, the number of bytes increments by 1.

13. When flag m is 0, the byte in the table is incremented by 1.

Symbols in machine instructions table

Symbol	Description	Symbol	Description
IMP	Implied addressing mode	∨	Exclusive OR
IMM	Immediate addressing mode	–	Negation
A	Accumulator addressing mode	←	Movement to the arrow direction
DIR	Direct addressing mode	Acc	Accumulator
DIR, b	Direct bit addressing mode	AccH	Accumulator's upper 8 bits
DIR, X	Direct indexed X addressing mode	AccL	Accumulator's lower 8 bits
DIR, Y	Direct indexed Y addressing mode	A	Accumulator A
(DIR)	Direct indirect addressing mode	AH	Accumulator A's upper 8 bits
(DIR,X)	Direct indexed X indirect addressing mode	AL	Accumulator A's lower 8 bits
(DIR), Y	Direct indirect indexed Y addressing mode	B	Accumulator B
L (DIR)	Direct indirect long addressing mode	BH	Accumulator B's upper 8 bits
L (DIR),Y	Direct indirect long indexed Y addressing mode	BL	Accumulator B's lower 8 bits
ABS	Absolute addressing mode	X	Index register X
ABS, b	Absolute bit addressing mode	XH	Index register X's upper 8 bits
ABS, X	Absolute indexed X addressing mode	XL	Index register X's lower 8 bits
ABS, Y	Absolute indexed Y addressing mode	Y	Index register Y
ABL	Absolute long addressing mode	YH	Index register Y's upper 8 bits
ABL, X	Absolute long indexed X addressing mode	YL	Index register Y's lower 8 bits
(ABS)	Absolute indirect addressing mode	S	Stack pointer
L (ABS)	Absolute indirect long addressing mode	PC	Program counter
(ABS, X)	Absolute indexed X indirect addressing mode	PC _H	Program counter's upper 8 bits
STK	Stack addressing mode	PC _L	Program counter's lower 8 bits
REL	Relative addressing mode	PG	Program bank register
DIR, b, REL	Direct bit relative addressing mode	DT	Data bank register
ABS, b, REL	Absolute bit relative addressing mode	DPR	Direct page register
SR	Stack pointer relative addressing mode	DPR _H	Direct page register's upper 8 bits
(SR), Y	Stack pointer relative indirect indexed Y addressing mode	DPR _L	Direct page register's lower 8 bits
BLK	Block transfer addressing mode	PS	Processor status register
C	Carry flag	PS _H	Processor status register's upper 8 bits
Z	Zero flag	PS _L	Processor status register's lower 8 bits
I	Interrupt disable flag	PS _b	Processor status register's b-th bit
D	Decimal operation mode flag	M(S)	Contents of memory at address indicated by stack pointer
x	Index register length selection flag	M _b	b-th memory location
m	Data length selection flag	AD _G	Value of 24-bit address's upper 8-bit (A ₂₃ –A ₁₆)
V	Overflow flag	AD _H	Value of 24-bit address's middle 8-bit (A ₁₅ –A ₈)
N	Negative flag	AD _L	Value of 24-bit address's lower 8-bit (A ₇ –A ₀)
IPL	Processor interrupt priority level	op	Operation code
+	Addition	n	Number of cycle
–	Subtraction	#	Number of byte
*	Multiplication	i	Number of transfer byte or rotation
/	Division	i ₁ , i ₂	Number of registers pushed or pulled
∧	Logical AND		
∨	Logical OR

Appendix 8. Countermeasure against noise

General countermeasure examples against noise are described below. Although the effect of these countermeasure depends on each system, refer to the following when an noise-related problem occurs.

1. Short wiring length

The wiring on a printed circuit board may function as an antenna which feeds noise into the microcomputer. The shorter the total wiring length (by mm unit), the less possibility of noise insertion into the microcomputer.

(1) Wiring for RESET pin

Make the length of wiring connected to the $\overline{\text{RESET}}$ pin as short as possible.

In particular, connect a capacitor between the $\overline{\text{RESET}}$ pin and the Vss pin with the shortest possible wiring (within 20 mm).

Reason: If noise is input to the $\overline{\text{RESET}}$ pin, the microcomputer restarts operation before the internal state of the microcomputer is completely initialized. This may cause a program runaway.

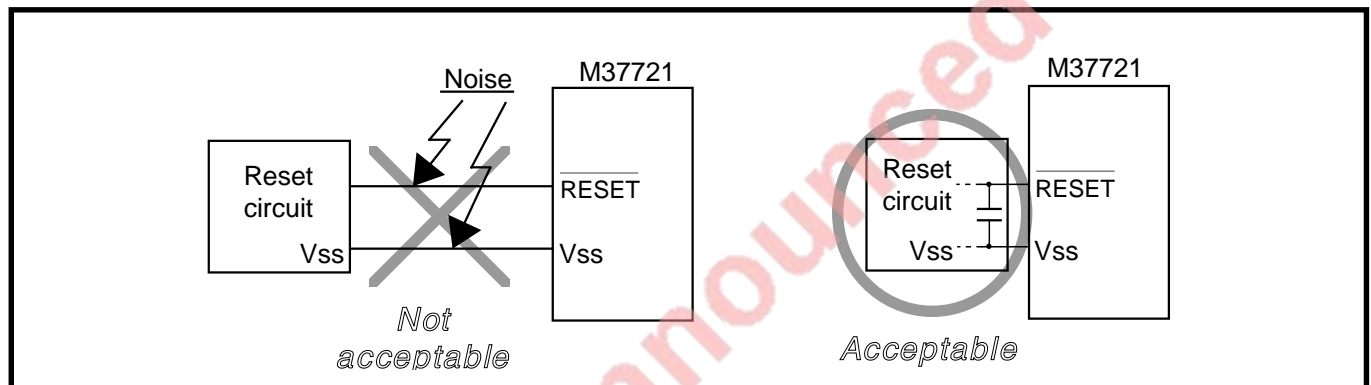

Fig. 3 Wiring for RESET pin

(2) Wiring for clock input/output pins

- Make the length of wiring connected to the clock input/output pins as short as possible.
- Make the length of wiring between the grounding lead of the capacitor, which is connected to the oscillator, and the Vss pin of the microcomputer, as short as possible (within 20 mm).
- Separate the Vss pattern for oscillation from all other Vss patterns. (Refer to “Figure 11.”)

Reason: The microcomputer’s operation synchronizes with a clock generated by the oscillation circuit.

If noise enters clock I/O pins, clock waveforms may be deformed. This may cause a malfunction or a program runaway.

Also, if the noise causes a potential difference between the Vss level of the microcomputer and the Vss level of an oscillator, the correct clock will not be input in the microcomputer.

Fig. 4 Wiring for clock input/output pins

APPENDIX

Appendix 8. Countermeasure against noise

(3) Wiring for CNVss pin

Connect CNVss pin to the Vss pin with the shortest possible wiring.

Reason: The processor mode of the microcomputer is influenced by a potential at the CNVss pin when the CNVss pin and the Vcc or Vss pin are connected. If the noise causes a potential difference between the CNVss pin and the Vss or Vcc pin, the processor mode may become unstable. This may cause a microcomputer malfunction or a program runaway.

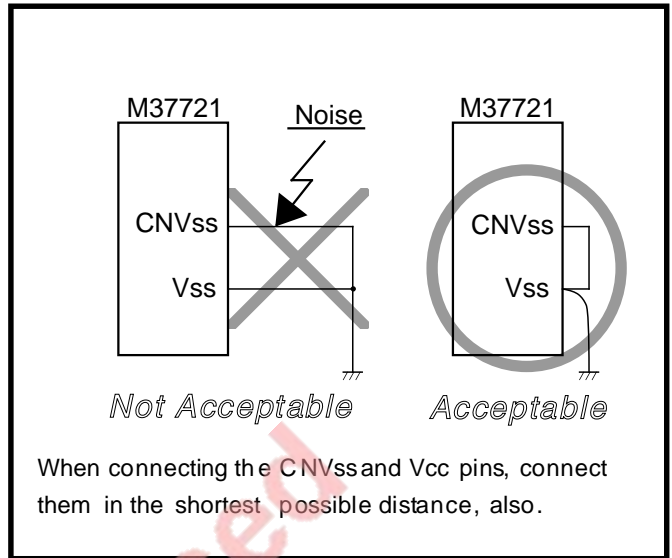

Fig. 5 Wiring for CNVss pin

2. Connection of bypass capacitor between Vss and Vcc lines

Connect an approximate 0.1 μF bypass capacitor as follows:

- Connect a bypass capacitor between the Vss and Vcc pins, at equal lengths.
- The wiring connecting the bypass capacitor between the Vss and Vcc pins should be as short as possible.
- Use thicker wiring for the Vss and Vcc lines than that for the other signal lines.

Fig. 6 Bypass capacitor between Vss and Vcc lines

3. Wiring for analog input pins, analog power source pins, etc.

(1) Processing for analog input pins

- Connect a resistor to the analog signal line, which is connected to an analog input pin, in series. Additionally, connect the resistor to the microcomputer as close as possible.
- Connect a capacitor between the analog input pin and the AVss pin, as close to the AVss pin as possible.

Reason: A signal which is input to the analog input pin is usually an output signal from a sensor. The sensor, which detects changes in status, is installed far from the microcomputer's printed circuit board. Therefore, this long wiring between them becomes an antenna which picks up noise and feeds it into the microcomputer's analog input pin.

If a capacitor between an analog input pin and the AVss pin is grounded far away from the AVss pin, noise on the GND line may enter the microcomputer through the capacitor.

Fig. 7 Countermeasure example against noise for analog input pin using thermistor

APPENDIX

Appendix 8. Countermeasure against noise

(2) Processing for analog power source pins, etc.

- Use independent power sources for the V_{CC}, AV_{CC} and V_{REF} pins.
- Insert capacitors between the AV_{CC} and AV_{SS} pins, and between the V_{REF} and AV_{SS} pins.

Reasons: Prevents the A-D converter from noise on the V_{CC} line.

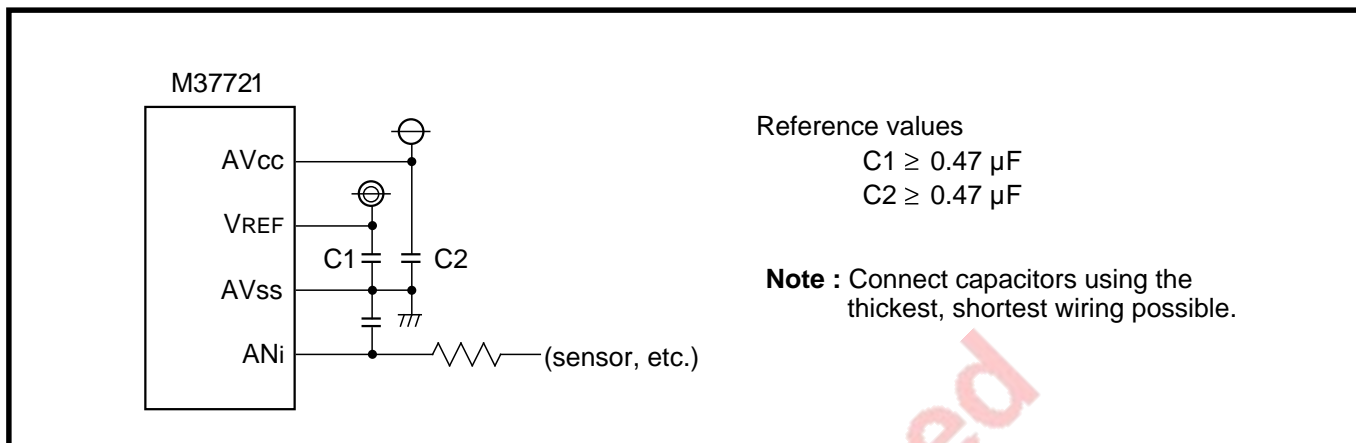

Fig. 8 Processing for analog power source pins, etc.

EOL announced

4. Oscillator protection

The oscillator, which generates the basic clock for the microcomputer operations, must be protected from the affect of other signals.

(1) Distance oscillator from signal lines with large current flows

Install the microcomputer, especially the oscillator, as far as possible from signal lines which handle currents larger than the microcomputer current value tolerance.

Reason: The microcomputer is used in systems which contain signal lines for controlling motors, LEDs, thermal heads, etc. Noise occurs due to mutual inductance when a large current flows through the signal lines.

Fig. 9 Wiring for signal lines where large current flows

(2) Distance oscillator from signal lines with frequent potential level changes

- Install an oscillator and its wiring pattern away from signal lines where potential levels change frequently.
- Do not cross these signal lines over the clock-related or noise-sensitive signal lines.

Reason: Signal lines with frequently changing potential levels may affect other signal lines at a rising or falling edge. In particular, if the lines cross over a clock-related signal line, clock waveforms may be deformed, which causes a microcomputer malfunction or a program runaway.

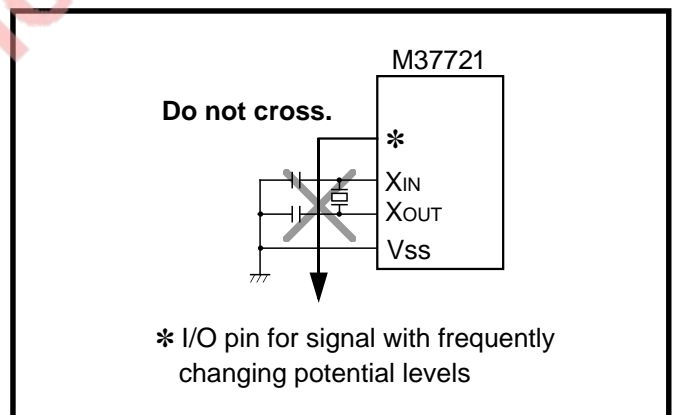

Fig. 10 Wiring for signal lines where potential levels frequently change

(3) Oscillator protection using Vss pattern

Print a Vss pattern on the bottom (soldering side) of a double-sided printed circuit board, under the oscillator mount position. Connect the Vss pattern to the Vss pin of the microcomputer with the shortest possible wiring, separating it from other Vss patterns.

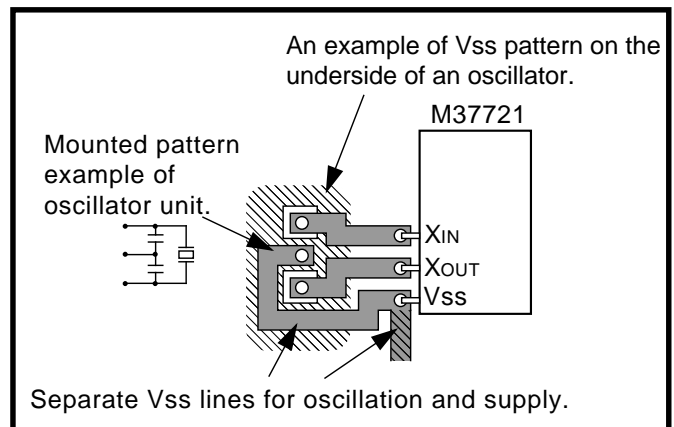

Fig. 11 Vss pattern underneath mounted oscillator

APPENDIX

Appendix 8. Countermeasure against noise

5. Setup for I/O ports

Setup I/O ports by hardware and software as follows:

<Hardware protection>

- Connect a resistor of 100 Ω or more to an I/O port in series.

<Software protection>

- Read the data of an input port several times to confirm that input levels are equal.
- Since the output data may reverse because of noise, rewrite data to the output port's Pi register periodically.
- Rewrite data to port Pi direction registers periodically.

Fig. 12 Setup for I/O ports

6. Reinforcement of the power source line

- For the Vss and Vcc lines, use thicker wiring than that of other signal lines.
- When using a multilayer printed circuit board, the Vss and Vcc patterns must each be one of the middle layers.
- The following is necessary for double-sided printed circuit boards:
 - On one side, the microcomputer is installed at the center, and the Vss line is looped or meshed around it. The vacant area is filled with the Vss line.
 - On the opposite side, the Vcc line is wired the same as the Vss line.
 - The power source lines of external devices which are connected by bus to the microcomputer must be connected to the microcomputer's power source lines with the shortest possible wiring.

Reasons: With external devices connected to the microcomputer, the levels of many of the signal lines (total external address buses: 24 bits) may change simultaneously, causing noise on the power source line.

Appendix 9. 7721 Group Q & A

Information which may be helpful in fully utilizing the 7721 Group is provided in Q & A format.

In Q & A, as a rule, one question and its answer are summarized within one page. The upper box on each page is a question, and a box below the question is its answer. (If a question or an answer extends to two or more pages, there is a page number at the lower right corner.)

At the upper right corner of each page, the main function related to the contents of description in that page is listed.

EOL announced

APPENDIX

Appendix 9. 7721 Group Q & A

SFR

Q

Is there any SFR to which a certain instruction cannot be used for writing ?

A

- (1) Use the **LDM** or **STA** instruction to write to the registers or the bits listed below. Do not use read-modify-write instructions (i.e., **CLB**, **SEB**, **ASL**, **ASR**, **DEC**, **INC**, **LSR**, **ROL**, and **ROR**).

Pulse output data register 0, 1 (addresses $1A_{16}$, $1C_{16}$)

UART0, 1 baud rate register (addresses 31_{16} , 39_{16})

UART0, 1 transmit buffer register (addresses 33_{16} , 32_{16} , $3B_{16}$, $3A_{16}$)

Timer A2–A4 two-phase pulse signal processing select bit (bits 5–7 at address 44_{16})

Timer A2–A4 register (addresses $4A_{16}$ – $4F_{16}$; one-shot pulse mode or pulse width modulation mode)

Refresh timer (address 66_{16})

- (2) Use the **SEB** or **CLB** instruction to write to the following register.

DMAC control register H (address 69_{16} ; when any of bits 4 to 7 = "1")

Reset, STP instruction, WIT instruction

Q

Is it possible to distinguish power-on reset from hardware reset for terminating the stop or wait mode ?

A

The contents of the internal RAM is undefined after power-on reset. On the other hand, the contents of the internal RAM are retained when performing hardware reset in the stop or wait mode with $V_{cc} \geq 2 \text{ V}$.

Accordingly, write a certain data to the internal RAM before executing **STP** or **WIT** instruction, and judge by checking the contents of the internal RAM after hardware reset.

EOL announced

APPENDIX

Appendix 9. 7721 Group Q & A

Interrupt

Q

If an interrupt request (b) occurs while executing an interrupt routine (a), is it true that the main routine is not executed at all from when the execution of the interrupt routine (a) is completed until the execution of the INTACK sequence for the next interrupt (b) starts?

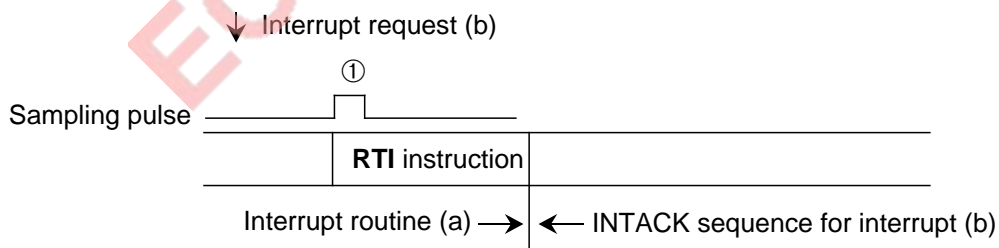

Conditions:

- I is cleared to "0" by executing the **RTI** instruction.
- Interrupt priority level of interrupt (b) is higher than IPL of main routine.
- Interrupt priority detection time is 2 cycles of ϕ .

A

Sampling for interrupt requests is performed by sampling pulses generated synchronously with the CPU's op-code fetch cycles.

- (1) If the next interrupt request (b) occurs before sampling pulse ① for the **RTI** instruction is generated, the microcomputer executes the INTACK sequence for (b) without executing the main routine (not even one instruction). It is because that sampling is completed while executing the **RTI** instruction.

- (2) If the next interrupt request (b) occurs immediately after sampling pulse ① is generated, the microcomputer executes one instruction of the main routine before executing the INTACK sequence for (b). It is because that the interrupt request is sampled by the next sampling pulse ②.

Q

Suppose that there is a routine which should not accept one certain interrupt request. (The other interrupt request are acceptable).

Although when the interrupt priority level select bits for the above interrupt are set to "0002," in other words, when this interrupt is set to be disabled, this interrupt request is actually accepted immediately after change of the priority level. Why did this occur and what should I do about it?

```

:
Interrupt request is  LDM #00H, XXXIC ; Writes "0002" to interrupt priority level select bits.
accepted in this →   ; Clears interrupt request bit to "0."
interval             LDA A,DATA      ; Instruction at the beginning of the routine which
:                                     should not accept one certain interrupt request.
:                                     ;
    
```

A

As for the change of the interrupt priority level, when the following are met, the microcomputer may pretend to accept an interrupt request immediately after this interrupt is set to be disabled:

- The next instruction (in the above example, it is the **LDA** instruction) is already stored into a instruction queue buffer for the BIU.
- Conditions for accepting the instruction which should not be accepted are satisfied immediately before the next instruction in the instruction queue buffer is executed.

When writing to a memory or an I/O, the CPU passes the address and data to the BIU. Then, the CPU executes the next instruction in the instruction queue buffer while the BIU is writing data into the actual address. Detection of interrupt priority level is performed at the beginning of each instruction.

In the above case, the CPU executes the next instruction before the BIU completes the change of the interrupt priority level. Therefore, when the interrupt priority level is detected synchronously with the execution of the next instruction, the interrupt priority level before the change is detected and its interrupt request is accepted.

(1/2)

APPENDIX

Appendix 9. 7721 Group Q & A

Interrupt

A

To prevent this problem, after change of the interrupt priority level is completed, use software to execute the routine that should not accept a certain interrupt request. The following shows a sample program.

[Sample program]

After an instruction which writes "0002" to the interrupt priority level select bits, fill the instruction queue buffer with the **NOP** instruction to make the next instruction not to be executed before the writing is completed.

```
      :  
      LDM #00H, XXXIC ; Sets the interrupt priority level select bits to "0002."  
      NOP              ;  
      NOP              ;  
      NOP              ;  
      LDA A,DATA      ; Instruction at the beginning of the routine that should not accept a certain  
      :                ; interrupt request
```

(2/2)

Q

- (1) Which timing of clock ϕ_1 is the external interrupts (input signals to the $\overline{\text{INT}}_i$ pin) detected?
- (2) How can four or more external interrupt input pins (INT_i) be used?

A

- (1) In both the edge sense and level sense, external interrupt requests occur when the input signal to the INT_i pin changes its level. This is independent of clock ϕ_1 .
In the edge sense, the interrupt request bit is set to “1” at this time.
- (2) There are two methods: one uses external interrupt’s level sense, and the other uses the timer’s event counter mode.

① Method using external interrupt’s level sense

As for hardware, input a logical sum of multiple interrupt signals (e.g., ‘a’, ‘b’, and ‘c’) to the $\overline{\text{INT}}_i$ pin, and input each signal to each corresponding port.

As for software, check the ports’ input levels in the $\overline{\text{INT}}_i$ interrupt routine in order to detect which signal (‘a’, ‘b’, or ‘c’) was input.

② Method using timer’s event counter mode

As for hardware, input interrupt signals to the $\text{TA}_{i\text{IN}}$ pins or $\text{TB}_{i\text{IN}}$ pins.

As for software, set the timer’s operating mode to the event counter mode. Then, set a value “0000₁₆” into the timer register and select the valid edge.

The timer’s interrupt request occurs when an interrupt signal (selected valid edge) is input.

APPENDIX

Appendix 9. 7721 Group Q & A

Stack, DRAM

Q

What are there the stack bank select bit (bit 7 at address 5E₁₆) for?

A

It is supposed that DRAM is used as the stack area.

When connecting DRAM, the stack pointer addressing mode or stack operation instruction etc. can be used. It is because all of 64 Kbytes can be used as the stack area when bank FF₁₆ which is assigned to DRAM is set as the stack area.

(The internal RAM also functions as the temporary area or the register file which is accessed frequently because the internal RAM can be accessed with no Wait. Accordingly, it is expected that the capacity will lack to be used as the stack area. As for the M37721, DRAM area can be set as the stack area because cheap DRAM can be connected.)

Use bank 0 which is assigned to the internal RAM area as the stack area when DRAM is not connected or the internal RAM is sufficient to be used as the stack area.

DRAM, WIT instruction

Q	Are there methods to refresh DRAM in the wait mode?
----------	---

EOL announced

APPENDIX

Appendix 9. 7721 Group Q & A

A

In the wait mode, DRAM refresh function does not operate, but the watchdog timer, timer A, and timer B operate. Accordingly, DRAM can be refreshed by using these timers and ports.

(1) Method using watchdog timer

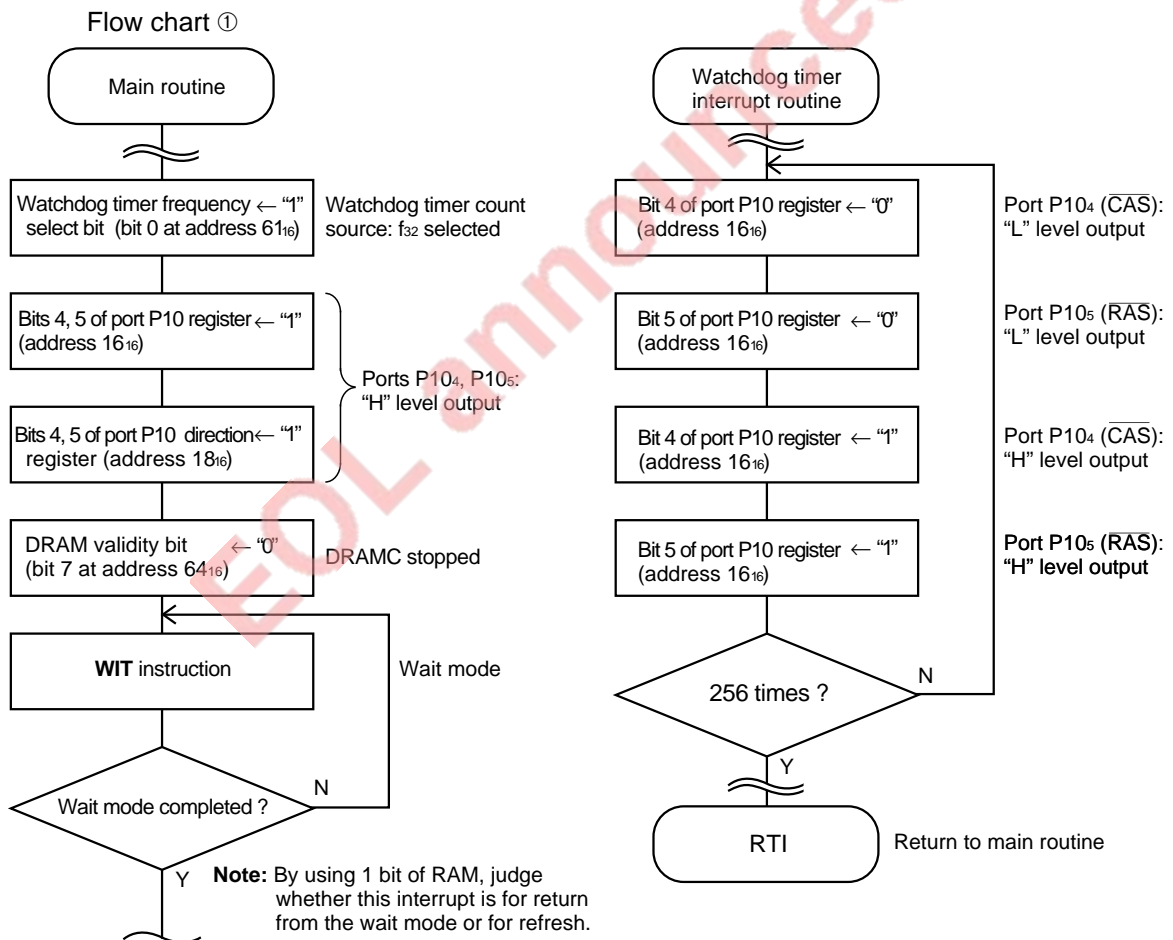

Return from the wait mode by the watchdog timer interrupt. Control ports P10₄, P10₅ by software and perform the CAS-before-RAS-refresh.

Interval of watchdog timer interrupt

f(X _{IN})	f ₃₂ selected	f ₅₁₂ selected
25 MHz	2.621 ms	41.943 ms
16 MHz	4.096 ms	65.536 ms

Example 1: A case in 1024 refresh cycles, every 16.4 ms, f(X_{IN}) = 16 MHz, watchdog timer count source = f₃₂

- DRAM refresh is performed 256 times. This refresh is performed by every watchdog timer interrupt. (See flow chart ①.)

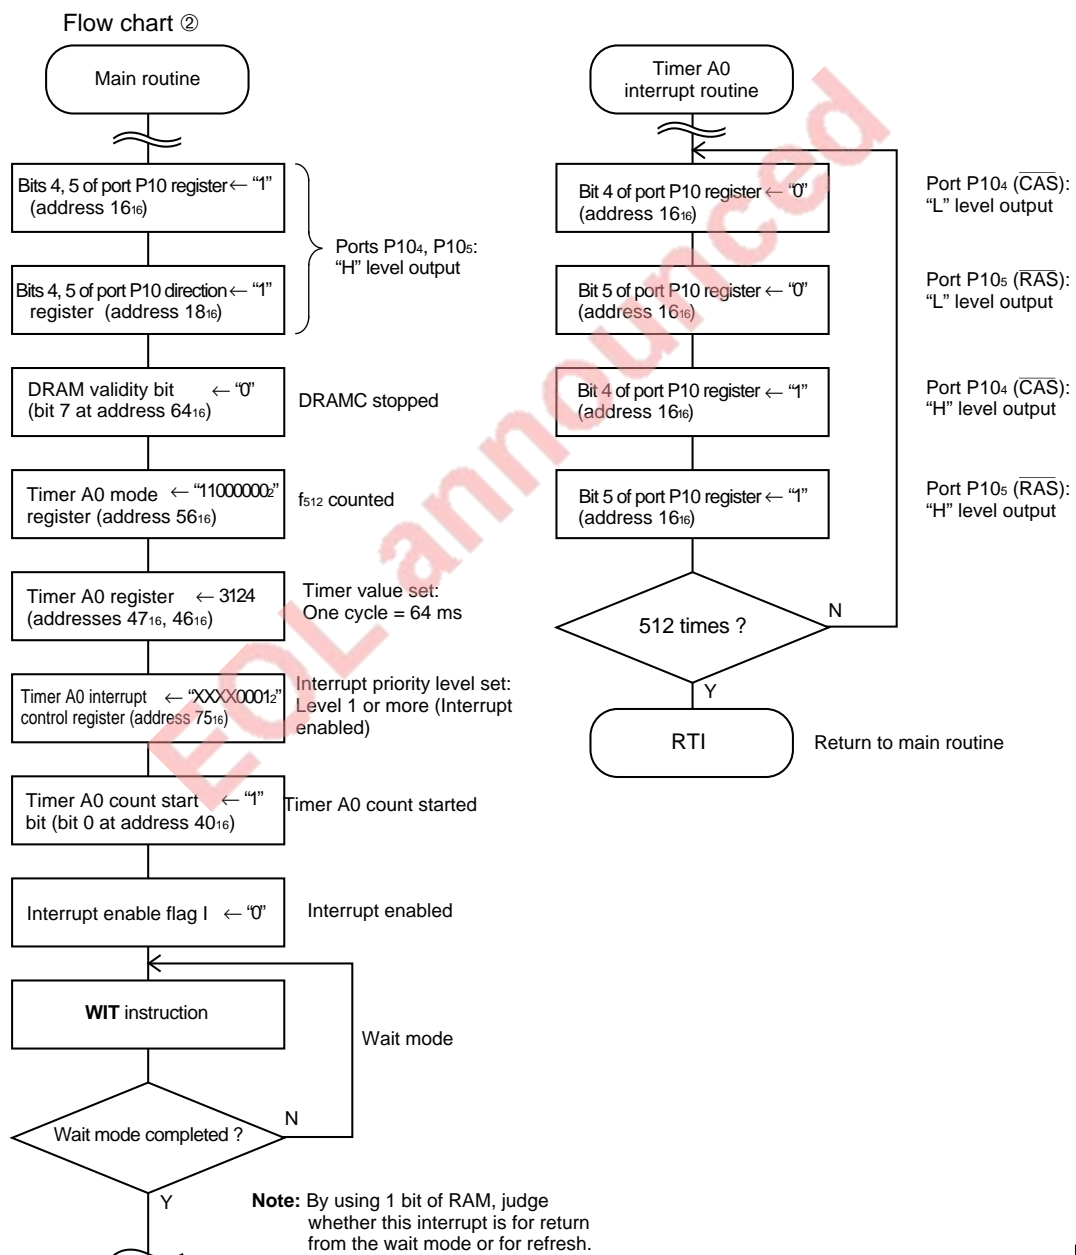

A

(2) Method using timer A or timer B

Return from the wait mode by a timer A (or timer B) interrupt every definite time. Control ports P10₄, P10₅ by software and perform the CAS-before-RAS-refresh.

Example 2: A case in 512 refresh cycles, every 64 ms, $f(X_{IN}) = 25$ MHz, timer A0 used

- DRAM refresh is performed 512 times by timer A0 interrupts. This interrupt occurs every 64 ms. (See flow chart ②.)

(2/2)

APPENDIX

Appendix 9. 7721 Group Q & A

DRAM

Q

How is the program execution time affected when using DRAM ?

A

When the M37721 uses DRAM, the execution time is affected as follows:

- CPU stops and DRAM refresh cycle is inserted.
- 1-bus cycle becomes 3ϕ when accessing DRAM.

- (1) Refresh method of the M37721's DRAMC is the dispersion refresh and 5 cycles of ϕ are necessary for one refresh. The rate occupied by the DRAM refresh cycle during the program execution time is described below.

Rate occupied by DRAM refresh cycle during program execution time

Refresh interval	Rate occupied by DRAM refresh cycle	
	$f(X_{IN}) = 25 \text{ MHz}$	$f(X_{IN}) = 16 \text{ MHz}$
15.625 μs (Case of 512 refresh cycles, every 8 ms)	2.6 %	4.2 %
125 μs (Case of 512 refresh cycles, every 64 ms)	0.3 %	0.5 %

- (2) The comparison results of two sample programs' execution times are listed below; one is for the case where SRAM is used and the other is for the case where DRAM is used.

Use conditions : Execution program Sample program B (See (2/2))
 $f(X_{IN})$ 16 MHz
 External data bus width 16 bits
 Refresh interval 13 μs

Memory used as work area	Software wait valid area	Execution time	Speed comparison
SRAM	Nothing	3.4 ms	1.00
SRAM	ROM and RAM	5.0 ms	1.47
DRAM (bank FF ₁₆)	Nothing	3.9 ms	1.15
DRAM (bank FF ₁₆)	ROM	5.2 ms	1.53

APPENDIX

Appendix 9. 7721 Group Q & A

Watchdog timer

Q

When detecting the software runaway by the watchdog timer, if the same value as the contents of the reset vector address is set to the watchdog timer interrupt vector address, not performing software reset, how does it result in?

When branching to the reset branch address within the watchdog timer interrupt routine, how does it result in?

A

The CPU registers and the SFR are not initialized in the above-mentioned way. Accordingly, the user must initialize all of them by software.

Note that the processor interrupt priority level (IPL) retains "7" of the watchdog timer interrupt priority level and is not initialized. Consequently, all interrupt requests cannot be accepted. When rewriting the IPL by software, save once the 16-bit immediate value to the stack area and then restore that 16-bit immediate value to all bits of the processor status register (PS).

When a software runaway occurs, we recommend to use software reset in order to initialize the microcomputer.

Appendix 10. Differences between 7721 Group and 7720 Group

Appendix 10. Differences between 7721 Group and 7720 Group

Table 2 Differences between M37721S2BFP and M37720S1AFP

Item		M37721S2BFP	M37720S1AFP
Internal RAM size		1024 bytes (Note)	512 bytes
External clock input frequency		25 MHz (maximum)	16 MHz (maximum)
Instruction execution time (minimum)		160 ns	250 ns
Real-time output	Bit configuration of real-time output channel	4 bits X 2 channels, or 6 bits X 1channel and 2 bits X 1channel	4 bits X 2 channels
	Port latch state after using real-time output	Retains the value before using real-time output	Undefined
Limitation for instruction used when writing to interrupt control register		Nothing (LDM, STA instructions can be used.)	Exists (LDM, STA instructions cannot be used.)
Serial I/O	Timing when overrun error flag becomes "0"	One of the following: •When setting the receive enable bit to "0" •When setting the serial I/O mode select bits to "000 ₂ "	One of the following: •When setting the receive enable bit to "0" •When setting the serial I/O mode select bits to "000 ₂ " •When reading the receive buffer register
	Conditions for outputting "L" of RTS signal in clock synchronous serial I/O mode	When all of the following are satisfied: •Receive enable bit = "1" •Reception is stopped. •Dummy data is present in the transmit buffer register	When all of the following are satisfied: •Receive enable bit = "1" •Reception is stopped.
DMA shortest transfer rate (At 1-bus cycle transfer)		12.5 Mbytes/sec	8 Mbytes/sec

Note: 512 bytes can be selected by software. For the M37721S1BFP, its internal RAM size is 512 bytes.

Appendix 12. Standard characteristics

Standard characteristics described below are just examples of the M37721S2BFP's characteristics and are not guaranteed. For each parameter's limits, refer to section "Appendix 11. Electrical characteristics."

1. Programmable I/O port (CMOS output) standard characteristics

(1) P-channel I_{OH} - V_{OH} characteristics

(2) N-channel I_{OL} - V_{OL} characteristics

APPENDIX

Appendix 12. Standard characteristics

2. I_{CC} - $f(X_{IN})$ standard characteristics

(1) I_{CC} - $f(X_{IN})$ characteristics on operating and at reset

Measurement condition ($V_{CC} = 5.0\text{ V}$, $T_a = 25\text{ }^\circ\text{C}$, $f(X_{IN})$: square waveform, microprocessor mode)

(2) Wait mode

Measurement condition ($V_{CC} = 5.0\text{ V}$, $T_a = 25\text{ }^\circ\text{C}$, $f(X_{IN})$: square waveform, microprocessor mode)

3. A-D converter standard characteristics

The lower lines of the graph indicate the absolute precision errors. These are expressed as the deviation from the ideal value when the output code changes. For example, the change in output code from 0 to 1 should occur at 10 mV, but the measured value is +2 mV. Accordingly, the measured point of change is $10 + 2 = 12$ mV.

The upper lines of the graph indicate the input voltage width for which the output code is constant. For example, the measured input voltage width for which the output code is 15 is 24 mV, so that the differential non-linear error is $24 - 20 = 4$ mV (0.2 LSB).

[Measurement conditions]

• $V_{CC} = 5$ V, $V_{REF} = 5.12$ V, $f(X_{IN}) = 25$ MHz, $T_a = 25$ °C, $\phi_{AD} = f_2$ divided by 2

GLOSSARY

EOL announced

GLOSSARY

This section briefly explains the terms used in this user's manual. The terms defined here apply to this manual only.

Term	Meaning	Relevant term
Access	Means performing read, write, or read and write. In DRAMC, also means performing DRAM refresh.	
Access space	An accessible memory space of up to 16 Mbytes.	Access
Access characteristics	Means whether accessible or not.	Access
Branch	Means moving the program's execution point (= address) to another location.	
Bus control signal	A generic name for ALE, \overline{E} , R/W, \overline{BLE} , BHE, RDY, HOLD, HLDA, BYTE, ST0, and ST1 signals.	
Countdown	Means decreasing by 1 and counting.	Countup
Count source	A signal that is counted by timers A and B, the UARTi baud rate register (BRGi) and the watchdog timer. That is f2, f16, f64, f512 selected by the count source select bits and others.	
Countup	Means increasing by 1 and counting.	Countdown
External area	An accessible area for external devices connected. It is up to 16-Mbyte external area.	Internal area
External bus	A generic name for the external address bus and the external data bus.	
External device	Devices connected externally to the microcomputer. A generic name for a memory, an I/O device and a peripheral IC.	
Internal area	An accessible internal area. A generic name for areas of the internal RAM and the SFR.	External area
Interrupt routine	A routine that is automatically executed when an interrupt request is accepted. Set the start address of this routine into the interrupt vector table.	
Overflow	A state where the countup resultant is greater than the counter resolution.	Underflow Countup
Read-modify-write instruction	An instruction that reads the memory contents, modifies them and writes back to the same address. Relevant instructions are the ASL , ASR , CLB , DEC , INC , LSR , ROL , ROR , SEB instructions.	
Signal required for access to external device	A generic name for bus control, address bus, and data bus signals.	Bus control signal
Stop mode	A state where the oscillation circuit halts and the program execution is stopped. By executing the STP instruction, the microcomputer enters the stop mode.	Wait mode
UART	Clock asynchronous serial I/O. When used to designate the name of a functional block, this term also means the serial I/O which can be switched to the clock synchronous serial I/O.	Clock synchronous serial I/O
Underflow	A state where the countdown resultant is greater than the counter resolution.	Overflow Countdown
Wait mode	A state where the oscillation circuit is operating, however, the program execution is stopped. By executing the WIT instruction, the microcomputer enters the wait mode.	Stop mode
