Hardware Manual

Renesas 16-Bit Single-Chip Microcomputer H8S Family/H8S/2100 Series H8S/2144B HD64F2144B H8S/2134B HD64F2134B

Rev.1.00 Revision Date: Jun.24, 2005

#### Keep safety first in your circuit designs!

Renesas Technology Corp. puts the maximum effort into making semiconductor products better and
more reliable, but there is always the possibility that trouble may occur with them. Trouble with
semiconductors may lead to personal injury, fire or property damage.
 Remember to give due consideration to safety when making your circuit designs, with appropriate
measures such as (i) placement of substitutive, auxiliary circuits, (ii) use of nonflammable material or
(iii) prevention against any malfunction or mishap.

#### Notes regarding these materials

- These materials are intended as a reference to assist our customers in the selection of the Renesas Technology Corp. product best suited to the customer's application; they do not convey any license under any intellectual property rights, or any other rights, belonging to Renesas Technology Corp. or a third party.
- 2. Renesas Technology Corp. assumes no responsibility for any damage, or infringement of any third-party's rights, originating in the use of any product data, diagrams, charts, programs, algorithms, or circuit application examples contained in these materials.
- 3. All information contained in these materials, including product data, diagrams, charts, programs and algorithms represents information on products at the time of publication of these materials, and are subject to change by Renesas Technology Corp. without notice due to product improvements or other reasons. It is therefore recommended that customers contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor for the latest product information before purchasing a product listed herein.
  - The information described here may contain technical inaccuracies or typographical errors. Renesas Technology Corp. assumes no responsibility for any damage, liability, or other loss rising from these inaccuracies or errors.
  - Please also pay attention to information published by Renesas Technology Corp. by various means, including the Renesas Technology Corp. Semiconductor home page (http://www.renesas.com).
- 4. When using any or all of the information contained in these materials, including product data, diagrams, charts, programs, and algorithms, please be sure to evaluate all information as a total system before making a final decision on the applicability of the information and products. Renesas Technology Corp. assumes no responsibility for any damage, liability or other loss resulting from the information contained herein.
- 5. Renesas Technology Corp. semiconductors are not designed or manufactured for use in a device or system that is used under circumstances in which human life is potentially at stake. Please contact Renesas Technology Corp. or an authorized Renesas Technology Corp. product distributor when considering the use of a product contained herein for any specific purposes, such as apparatus or systems for transportation, vehicular, medical, aerospace, nuclear, or undersea repeater use.
- 6. The prior written approval of Renesas Technology Corp. is necessary to reprint or reproduce in whole or in part these materials.
- 7. If these products or technologies are subject to the Japanese export control restrictions, they must be exported under a license from the Japanese government and cannot be imported into a country other than the approved destination.
  - Any diversion or reexport contrary to the export control laws and regulations of Japan and/or the country of destination is prohibited.
- 8. Please contact Renesas Technology Corp. for further details on these materials or the products contained therein.

## **General Precautions on Handling of Product**

#### 1. Treatment of NC Pins

Note: Do not connect anything to the NC pins.

The NC (not connected) pins are either not connected to any of the internal circuitry or are used as test pins or to reduce noise. If something is connected to the NC pins, the operation of the LSI is not guaranteed.

#### 2. Treatment of Unused Input Pins

Note: Fix all unused input pins to high or low level.

Generally, the input pins of CMOS products are high-impedance input pins. If unused pins are in their open states, intermediate levels are induced by noise in the vicinity, a pass-through current flows internally, and a malfunction may occur.

#### 3. Processing before Initialization

Note: When power is first supplied, the product's state is undefined.

The states of internal circuits are undefined until full power is supplied throughout the chip and a low level is input on the reset pin. During the period where the states are undefined, the register settings and the output state of each pin are also undefined. Design your system so that it does not malfunction because of processing while it is in this undefined state. For those products which have a reset function, reset the LSI immediately after the power supply has been turned on.

#### 4. Prohibition of Access to Undefined or Reserved Addresses

Note: Access to undefined or reserved addresses is prohibited.

The undefined or reserved addresses may be used to expand functions, or test registers may have been be allocated to these addresses. Do not access these registers; the system's operation is not guaranteed if they are accessed.

# Configuration of This Manual

This manual comprises the following items:

- 1. General Precautions on Handling of Product
- 2. Configuration of This Manual
- 3. Preface
- 4. Contents
- 5. Overview
- 6. Description of Functional Modules
  - CPU and System-Control Modules
  - On-Chip Peripheral Modules

The configuration of the functional description of each module differs according to the module. However, the generic style includes the following items:

- i) Feature
- ii) Input/Output Pin
- iii) Register Description
- iv) Operation
- v) Usage Note

When designing an application system that includes this LSI, take notes into account. Each section includes notes in relation to the descriptions given, and usage notes are given, as required, as the final part of each section.

- 7. List of Registers
- 8. Electrical Characteristics
- 9. Appendix
- 10. Main Revisions and Additions in this Edition (only for revised versions)

The list of revisions is a summary of points that have been revised or added to earlier versions. This does not include all of the revised contents. For details, see the actual locations in this manual.

11. Index

## **Preface**

The H8S/2144B and H8S/2134B are microcomputers (MCUs) made up of the H8S/2000 CPU employing Renesas Technology's original architecture as their cores, and the peripheral functions required to configure a system.

Target Users: This manual was written for users who will be using the H8S/2144B or

H8S/2134B in the design of application systems. Target users are expected to

understand the fundamentals of electrical circuits, logical circuits, and

microcomputers.

Objective: This manual was written to explain the hardware functions and electrical

characteristics of the H8S/2144B and H8S/2134B to the target users.

Refer to the H8S/2600 Series, H8S/2000 Series Software Manual for a detailed

description of the instruction set.

Notes on reading this manual:

• In order to understand the overall functions of the chip

Read the manual according to the contents. This manual can be roughly categorized into parts
on the CPU, system control functions, peripheral functions and electrical characteristics.

In order to understand the details of the CPU's functions
 Read the H8S/2600 Series, H8S/2000 Series Software Manual.

• In order to understand the details of a register when its name is known

Read the index that is the final part of the manual to find the page number of the entry on the

register. The addresses, bits, and initial values of the registers are summarized in section 19, List of Registers.

List of Registers.

Rules: Register name: The following notation is used for cases when the same or a

similar function, e.g. serial communication interface, is

implemented on more than one channel:

XXX\_N (XXX is the register name and N is the channel

number)

Bit order: The MSB is on the left and the LSB is on the right.

Number notation: Binary is B'xxxx, hexadecimal is H'xxxx, decimal is xxxx.

Signal notation: An overbar is added to a active-low signal:  $\overline{xxxx}$ 

Related Manuals: The latest versions of all related manuals are available from our web site.

The latest versions of all related mandals are available from our web site.

Please ensure you have the latest versions of all documents you require.

## Section 1 Overview

#### 1.1 Features

High-speed H8S/2000 central processing unit with an internal 16-bit architecture

Upward-compatible with H8/300 and H8/300H CPUs on an object level

Sixteen 16-bit general registers

65 basic instructions

• Various peripheral functions

14-bit PWM timer (PWMX)

16-bit free-running timer (FRT)

8-bit timer (TMR)

Watchdog timer (WDT)

Asynchronous or clock synchronous serial communication interface (SCI, IrDA)

8-bit D/A converter

10-bit A/D converter

Clock pulse generator

### On-chip memory

ROM	Model	ROM	RAM	Remarks
Flash memory version	HD64F2144B	128 kbytes	4 kbytes	
	HD64F2134B	128 kbytes	4 kbytes	_

General I/O ports

I/O pins: 74 (H8S/2144B) and 58 (H8S/2134B)

Input-only pins: 8

• Supports various power-down modes

• Compact package

Product	Package	Code	Body Size	Pin Pitch
H8S/2144B	QFP-100B	FP-100B	16.0 × 16.0 mm	0.5 mm
	TQFP-100B	TFP-100B		
H8S/2134B	QFP-80A	FP-80A	17.2 × 17.2 mm	0.65 mm
	TQFP-80C	TFP-80C	$14.0\times14.0\;mm$	0.5 mm

# **1.3.3** Pin Functions

**Table 1.3 Pin Functions** 

		Pin	No.		
Type	Symbol	[H8S/2144B] FP-100B, TFP-100B	[H8S/2134B] FP-80A, TFP- 80C	1/0	Name and Function
Power	VCC	59	47	1	
rowei		39	47	!	Power supply pin. Connect this pin to the system power supply.
	VCL	9	8	I	Pin for connecting an external capacitor for the internal step-down circuit. This pin should be connected to the VSS via the external capacitor. Do not connect to the VCC. For details, see section 20, Electrical Characteristics.
	VCCB	4	_	I	The power supply pin for the input/output buffers of port A. Available only for the H8S/2144B.
	VSS	15, 70, 71, 92	12, 56, 73	I	Ground pins. Connect all the pins to the system power supply (0 V).
Clock	XTAL	2	2	I	Pins for connection to a crystal resonator. An
	EXTAL	3	3	I	external clock can be input on the EXTAL pin.
-					See section 17, Clock Pulse Generator, for typical connection diagrams.
	ф	17	14	0	Supplies the system clock to external devices.
	EXCL	17	14	I	Input an external 32.768-kHz clock for the subclock.
Operating mode control	MD1, MD0	5, 6	4, 5	I	These pins set the operating mode. The relationship between these signals and the operating mode is shown below. Signal levels on these pins should not be changed during operation.
					MD1 MD0 Operating Mode

		Pin No.			
		[H8S/2144B] FP-100B,	[H8S/2134B] FP-80A, TFP-	-	
Туре	Symbol	TFP-100B	80C	I/O	Name and Function
System	RES	1	1	I	Reset pin.
control					When this signal is driven low, this LSI enters the reset state.
	RESO	100	_	0	Outputs a reset to external devices. Available only for the H8S/2144B.
	STBY	8	7	I	When this signal is driven low, a transition is made to the hardware standby mode.
Address bus	A23 to A16	10, 11, 20, 21, 30, 31, 47, 48	_	0	Address output pins when an 16-bit access space is used. Available only for the H8S/2144B.
	A15 to A0	60 to 67, 72 to 79	48 to 55, 57 to 64	0	Address output pins
Data bus	D15 to D8	89 to 82	_	I/O	Bidirectional bus for data accessed in units of 8 bits or for the upper byte data accessed in units of 16 bits. Available only for the H8S/2144B.
	D7 to D0	57, 58, 68, 69, 80, 81, 90, 91	72 to 65	I/O	Bidirectional bus for the lower byte data accessed in units of 16 bits in the H8S/2144B.
					Bidirectional bus for data accessed in units of 8 bits in the H8S/2134B.
Bus control	WAIT	16	13	I	Requests insertion of a wait in the bus cycle when accessing the external 3-state address space.
	RD	22	17	0	When the signal level is low, it indicates that the external address space is being read from.
	WR	_	16	0	When the signal level is low, it indicates that the external address space is being written to. Available only for the H8S/2134B.
	HWR	19	_	0	When the signal level is low, it indicates that the external address space is being written to. The upper byte of the data bus is valid. Available only for the H8S/2144B.
	LWR	25	_	0	When the signal level is low, it indicates that the external address space is being written to. The lower byte of the data bus is valid. Available only for the H8S/2144B.

		Pin	No.		
Туре	Symbol	[H8S/2144B] FP-100B, TFP-100B	[H8S/2134B] FP-80A, TFP- 80C	1/0	Name and Function
Bus control	AS/IOS	18	15	0	Strobe signal. When the signal level is low, it indicates that address outputs on the address bus is valid or an I/O select signal is output. Set the register to select the function to be used.
Interrupt signals	NMI	7	6	I	Input pin for a nonmaskable interrupt request.
	IRQ0 to IRQ7	23 to 25, 97 to 99, 34, 35	18 to 20 78 to 80, 27, 28	I	Input pins for maskable interrupts.
16-bit	FTCI	26	21	I	The counter clock input pin.
free- running	FTOA	27	22	0	The output compare A output pin.
timer	FTOB	34	27	0	The output compare B output pin.
(FRT)	FTIA	28	23	I	The input capture A input pin.
	FTIB	29	24	I	The input capture B input pin.
_	FTIC	32	25	I	The input capture C input pin.
	FTID	33	26	I	The input capture D input pin.

	PB7 to PB0	57, 58, 68, 69, 80, 81, 90, 91	_	I/O	8-bit input/output pins with input pull-up MOSs. Available only for the H8S/2144B.

# Section 2 CPU

The H8S/2000 CPU is a high-speed central processing unit with an internal 32-bit architecture that is upward-compatible with the H8/300 and H8/300H CPUs. The H8S/2000 CPU has sixteen 16-bit general registers, can address a 16-Mbyte linear address space, and is ideal for realtime control.

This section describes the H8S/2000 CPU. The usable modes and address spaces differ depending on the product. For details on each product, refer to section 3, MCU Operating Modes.

#### 2.1 Features

- Upward-compatibility with H8/300 and H8/300H CPUs
   Can execute H8/300 CPU and H8/300H CPU object programs
- General-register architecture

Sixteen 16-bit general registers also usable as sixteen 8-bit registers or eight 32-bit registers

Sixty-five basic instructions

8/16/32-bit arithmetic and logic instructions

Multiply and divide instructions

Powerful bit-manipulation instructions

• Eight addressing modes

Register direct [Rn]

Register indirect [@ERn]

Register indirect with displacement [@(d:16,ERn) or @(d:32,ERn)]

Register indirect with post-increment or pre-decrement [@ERn+ or @-ERn]

Absolute address [@aa:8, @aa:16, @aa:24, or @aa:32]

Immediate [#xx:8, #xx:16, or #xx:32]

Program-counter relative [@(d:8,PC) or @(d:16,PC)]

Memory indirect [@@aa:8]

16-Mbyte address space

Program: 16 Mbytes

Data: 16 Mbytes

High-speed operation

All frequently-used instructions are executed in one or two states

8/16/32-bit register-register add/subtract: 1 state

8 × 8-bit register-register multiply: 12 states (MULXU.B), 13 states (MULXS.B)

16 ÷ 8-bit register-register divide: 12 states (DIVXU.B)

16 × 16-bit register-register multiply: 20 states (MULXU.W), 21 states (MULXS.W)

32 ÷ 16-bit register-register divide: 20 states (DIVXU.W)

• Two CPU operating modes

Normal mode

Advanced mode

Power-down state

Transition to power-down state by SLEEP instruction

Selectable CPU clock speed

#### 2.1.1 Differences between H8S/2600 CPU and H8S/2000 CPU

The differences between the H8S/2600 CPU and the H8S/2000 CPU are as shown below.

- Register configuration
  - The MAC register is supported only by the H8S/2600 CPU.
- Basic instructions

The four instructions MAC, CLRMAC, LDMAC, and STMAC are supported only by the H8S/2600 CPU.

The number of execution states of the MULXU and MULXS instructions

		Execution States		
Instruction	Mnemonic	H8S/2600	H8S/2000	
MULXU	MULXU.B Rs, Rd	3	12	
	MULXU.W Rs, ERd	4	20	
MULXS	MULXS.B Rs, Rd	4	13	
	MULXS.W Rs, ERd	5	21	

In addition, there are differences in address space, CCR and EXR register functions, power-down modes, etc., depending on the model.

#### 2.1.2 Differences from H8/300 CPU

In comparison to the H8/300 CPU, the H8S/2000 CPU has the following enhancements.

- More general registers and control registers
   Eight 16-bit extended registers and one 8-bit control register have been added.
- Expanded address space

Normal mode supports the same 64-kbyte address space as the H8/300 CPU.

Advanced mode supports a maximum 16-Mbyte address space.

### Enhanced addressing

The addressing modes have been enhanced to make effective use of the 16-Mbyte address space.

#### Enhanced instructions

Addressing modes of bit-manipulation instructions have been enhanced.

Signed multiply and divide instructions have been added.

Two-bit shift and two-bit rotate instructions have been added.

Instructions for saving and restoring multiple registers have been added.

A test and set instruction has been added.

### Higher speed

Basic instructions are executed twice as fast.

#### 2.1.3 Differences from H8/300H CPU

In comparison to the H8/300H CPU, the H8S/2000 CPU has the following enhancements.

### • Additional control register

One 8-bit control register has been added.

#### Enhanced instructions

Addressing modes of bit-manipulation instructions have been enhanced.

Two-bit shift and two-bit rotate instructions have been added.

Instructions for saving and restoring multiple registers have been added.

A test and set instruction has been added.

# Higher speed

Basic instructions are executed twice as fast.

# 2.2 **CPU Operating Modes**

The H8S/2000 CPU has two operating modes: normal and advanced. Normal mode supports a maximum 64-kbyte address space. Advanced mode supports a maximum 16-Mbyte address space. The mode is selected by the LSI's mode pins.

#### 2.2.1 Normal Mode

The exception vector table and stack have the same structure as in the H8/300 CPU in normal mode.

- Address space
  - Linear access to a maximum address space of 64 kbytes is possible.
- Extended registers (En)
  - The extended registers (E0 to E7) can be used as 16-bit registers, or as the upper 16-bit segments of 32-bit registers.
  - When extended register En is used as a 16-bit register it can contain any value, even when the corresponding general register (Rn) is used as an address register. (If general register Rn is referenced in the register indirect addressing mode with pre-decrement (@-Rn) or post-increment (@Rn+) and a carry or borrow occurs, the value in the corresponding extended register (En) will be affected.)
- · Instruction set
  - All instructions and addressing modes can be used. Only the lower 16 bits of effective addresses (EA) are valid.
- · Exception vector table and memory indirect branch addresses
  - In normal mode, the top area starting at H'0000 is allocated to the exception vector table. One branch address is stored per 16 bits. The exception vector table in normal mode is shown in figure 2.1. For details on the exception vector table, see section 4, Exception Handling. The memory indirect addressing mode (@@aa:8) employed in the JMP and JSR instructions
  - uses an 8-bit absolute address included in the instruction code to specify a memory operand that contains a branch address. In normal mode, the operand is a 16-bit (word) operand, providing a 16-bit branch address. Branch addresses can be stored in the top area from H'0000 to H'00FF. Note that this area is also used for the exception vector table.
- Stack structure
  - In normal mode, when the program counter (PC) is pushed onto the stack in a subroutine call in normal mode, and the PC and condition-code register (CCR) are pushed onto the stack in exception handling, they are stored as shown in figure 2.2. The extended control register (EXR) is not pushed onto the stack. For details, see section 4, Exception Handling.

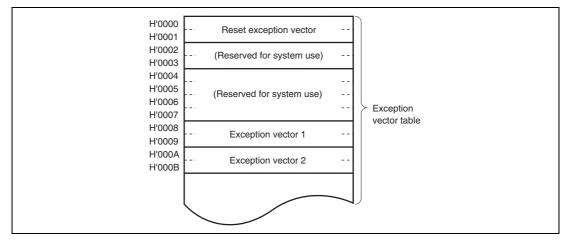

Figure 2.1 Exception Vector Table (Normal Mode)

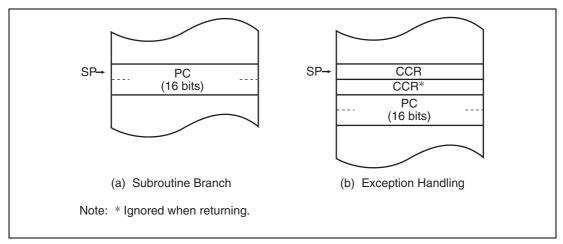

Figure 2.2 Stack Structure in Normal Mode

#### 2.2.2 Advanced Mode

- Address space
   Linear access to a maximum address space of 16 Mbytes is possible.
- Extended registers (En)
   The extended registers (E0 to E7) can be used as 16-bit registers. They can also be used as the upper 16-bit segments of 32-bit registers or address registers.
- Instruction set
   All instructions and addressing modes can be used.
- Exception vector table and memory indirect branch addresses

  In advanced mode, the top area starting at H'00000000 is allocated to the exception vector table in 32-bit units. In each 32 bits, the upper 8 bits are ignored and a branch address is stored in the lower 24 bits (see figure 2.3). For details on the exception vector table, see section 4, Exception Handling.

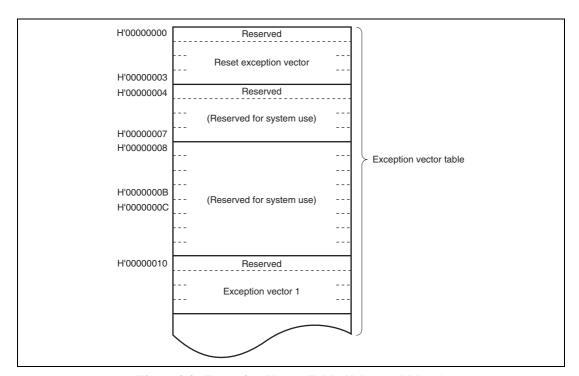

Figure 2.3 Exception Vector Table (Advanced Mode)

The memory indirect addressing mode (@@aa:8) employed in the JMP and JSR instructions uses an 8-bit absolute address included in the instruction code to specify a memory operand that contains a branch address. In advanced mode, the operand is a 32-bit longword operand, providing a 32-bit branch address. The upper 8 bits of these 32 bits are a reserved area that is regarded as H'00. Branch addresses can be stored in the area from H'00000000 to H'000000FF. Note that the top area of this range is also used for the exception vector table.

#### Stack structure

In advanced mode, when the program counter (PC) is pushed onto the stack in a subroutine call, and the PC and condition-code register (CCR) are pushed onto the stack in exception handling, they are stored as shown in figure 2.4. The extended control register (EXR) is not pushed onto the stack. For details, see section 4, Exception Handling.

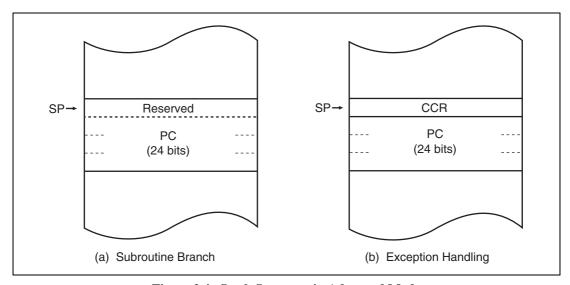

Figure 2.4 Stack Structure in Advanced Mode

REJ09B0241-0100

# 2.3 Address Space

Figure 2.5 shows a memory map of the H8S/2000 CPU. The H8S/2000 CPU provides linear access to a maximum 64-kbyte address space in normal mode, and a maximum 16-Mbyte (architecturally 4-Gbyte) address space in advanced mode. The usable modes and address spaces differ depending on the product. For details on each product, refer to section 3, MCU Operating Modes.

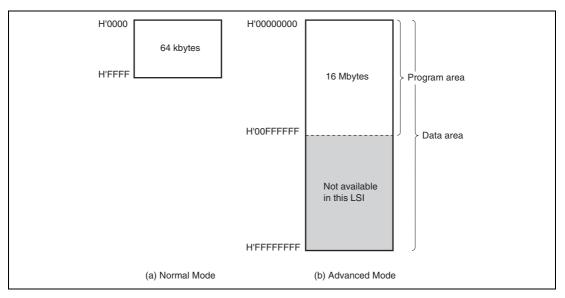

Figure 2.5 Memory Map

# 2.4 Register Configuration

The H8S/2000 CPU has the internal registers shown in figure 2.6. There are two types of registers: general registers and control registers. Control registers are a 24-bit program counter (PC), an 8-bit extended control register (EXR), and an 8-bit condition code register (CCR).

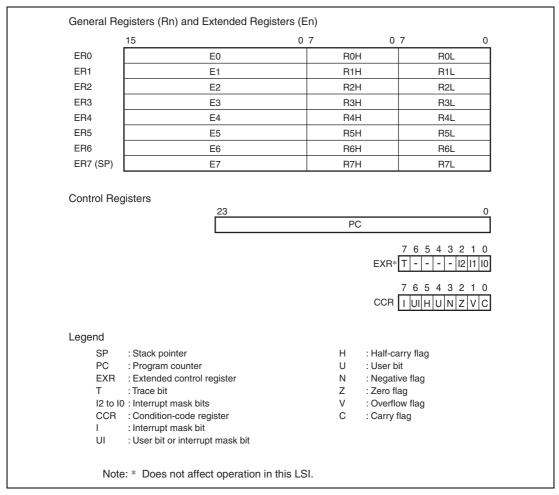

Figure 2.6 CPU Internal Registers

### 2.4.1 General Registers

The H8S/2000 CPU has eight 32-bit general registers. These general registers are all functionally alike and can be used as both address registers and data registers. When a general register is used as a data register, it can be accessed as a 32-bit, 16-bit, or 8-bit register. Figure 2.7 illustrates the usage of the general registers.

When the general registers are used as 32-bit registers or address registers, they are designated by the letters ER (ER0 to ER7).

When the general registers are used as 16-bit registers, the ER registers are divided into 16-bit general registers designated by the letters E (E0 to E7) and R (R0 to R7). These registers are functionally equivalent, providing a maximum sixteen 16-bit registers. The E registers (E0 to E7) are also referred to as extended registers.

When the general registers are used as 8-bit registers, the R registers are divided into 8-bit general registers designated by the letters RH (R0H to R7H) and RL (R0L to R7L). These registers are functionally equivalent, providing a maximum sixteen 8-bit registers.

The usage of each register can be selected independently.

General register ER7 has the function of the stack pointer (SP) in addition to its general-register function, and is used implicitly in exception handling and subroutine calls. Figure 2.8 shows the stack.

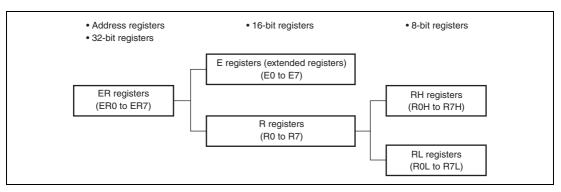

Figure 2.7 Usage of General Registers

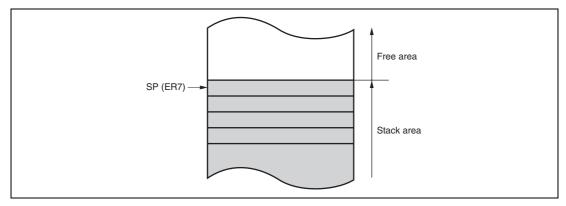

Figure 2.8 Stack

### 2.4.2 Program Counter (PC)

This 24-bit counter indicates the address of the next instruction the CPU will execute. The length of all CPU instructions is 2 bytes (one word), so the least significant PC bit is ignored. (When an instruction is fetched for read, the least significant PC bit is regarded as 0.)

### 2.4.3 Extended Control Register (EXR)

EXR does not affect operation in this LSI.

Bit	Bit Name	Initial Value	R/W	Description
7	T	0	R/W	Trace Bit
				Does not affect operation in this LSI.
6 to 3	_	All 1	R	Reserved
				These bits are always read as 1.
2 to 0	12	All 1	R/W	Interrupt Mask Bits 2 to 0
	l1			Do not affect operation in this LSI.
	10			

## 2.4.4 Condition-Code Register (CCR)

This 8-bit register contains internal CPU status information, including an interrupt mask bit (I) and half-carry (H), negative (N), zero (Z), overflow (V), and carry (C) flags. Operations can be performed on the CCR bits by the LDC, STC, ANDC, ORC, and XORC instructions. The N, Z, V, and C flags are used as branching conditions for conditional branch (Bcc) instructions.

Bit	Bit Name	Initial Value	R/W	Description
7		1	R/W	Interrupt Mask Bit
				Masks interrupts other than NMI when set to 1. NMI is accepted regardless of the I bit setting. The I bit is set to 1 at the start of an exception-handling sequence. For details, refer to section 5, Interrupt Controller.
6	UI	Undefined	R/W	User Bit or Interrupt Mask Bit
				Can be written to and read from by software using the LDC, STC, ANDC, ORC, and XORC instructions.
5	Н	Undefined	R/W	Half-Carry Flag
				When the ADD.B, ADDX.B, SUB.B, SUBX.B, CMP.B or NEG.B instruction is executed, this flag is set to 1 if there is a carry or borrow at bit 3, and cleared to 0 otherwise. When the ADD.W, SUB.W, CMP.W, or NEG.W instruction is executed, the H flag is set to 1 if there is a carry or borrow at bit 11, and cleared to 0 otherwise. When the ADD.L, SUB.L, CMP.L, or NEG.L instruction is executed, the H flag is set to 1 if there is a carry or borrow at bit 27, and cleared to 0 otherwise.
4	U	Undefined	R/W	User Bit
				Can be written to and read from by software using the LDC, STC, ANDC, ORC, and XORC instructions.
3	N	Undefined	R/W	Negative Flag
				Stores the value of the most significant bit of data as a sign bit.
2	Z	Undefined	R/W	Zero Flag
				Set to 1 to indicate zero data, and cleared to 0 to indicate non-zero data.
1	V	Undefined	R/W	Overflow Flag
				Set to 1 when an arithmetic overflow occurs, and cleared to 0 otherwise. $ \\$
0	С	Undefined	R/W	Carry Flag
				Set to 1 when a carry occurs, and cleared to 0 otherwise. Used by
				Add instructions, to indicate a carry
				Subtract instructions, to indicate a borrow
				Shift and rotate instructions, to indicate a carry
				The carry flag is also used as a bit accumulator by bit manipulation instructions.

### 2.4.5 Initial Register Values

The program counter (PC) among CPU internal registers is initialized when reset exception handling loads a start address from a vector table. The trace (T) bit in EXR is cleared to 0, and the interrupt mask (I) bits in CCR and EXR are set to 1. The other CCR bits and the general registers are not initialized. Note that the stack pointer (ER7) is undefined. The stack pointer should therefore be initialized by an MOV.L instruction executed immediately after a reset.

#### 2.5 Data Formats

The H8S/2000 CPU can process 1-bit, 4-bit BCD, 8-bit (byte), 16-bit (word), and 32-bit (longword) data. Bit-manipulation instructions operate on 1-bit data by accessing bit n (n = 0, 1, 2, ..., 7) of byte operand data. The DAA and DAS decimal-adjust instructions treat byte data as two digits of 4-bit BCD data.

### 2.5.1 General Register Data Formats

Figure 2.9 shows the data formats of general registers.

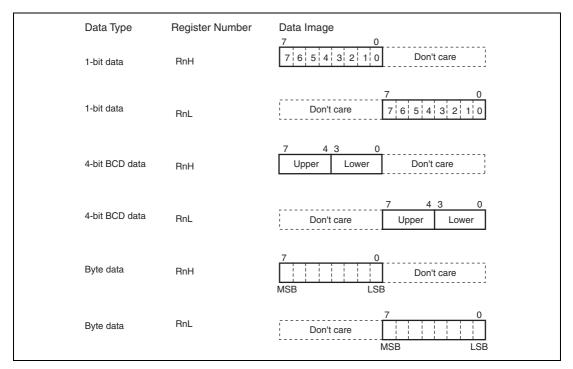

Figure 2.9 General Register Data Formats (1)

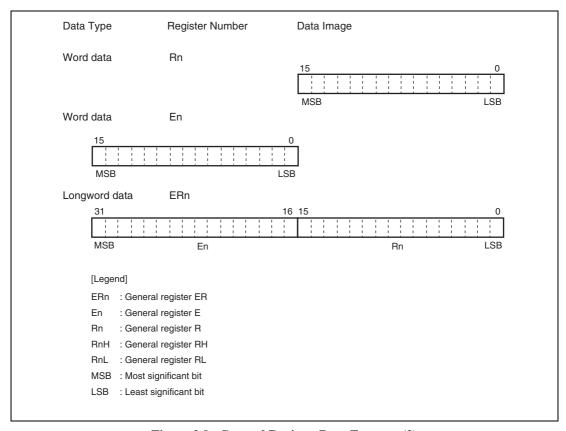

Figure 2.9 General Register Data Formats (2)

### 2.5.2 Memory Data Formats

Figure 2.10 shows the data formats in memory. The H8S/2000 CPU can access word data and longword data in memory, but word or longword data must begin at an even address. If an attempt is made to access word or longword data at an odd address, no address error occurs but the least significant bit of the address is regarded as 0, so the access starts at the preceding address. This also applies to instruction fetches.

When SP (ER7) is used as an address register to access the stack, the operand size should be word size or longword size.

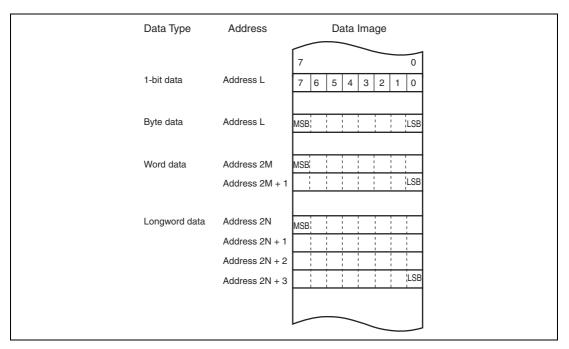

Figure 2.10 Memory Data Formats

### 2.6 Instruction Set

The H8S/2000 CPU has 65 types of instructions. The instructions are classified by function as shown in table 2.1.

**Table 2.1 Instruction Classification** 

Function	Instructions	Size	Types
Data transfer	MOV	B/W/L	5
	POP* <sup>1</sup> , PUSH* <sup>1</sup>	W/L	_
	LDM* <sup>5</sup> , STM* <sup>5</sup>	L	_
	MOVFPE* <sup>3</sup> , MOVTPE* <sup>3</sup>	В	_
Arithmetic	ADD, SUB, CMP, NEG	B/W/L	19
operations	ADDX, SUBX, DAA, DAS	В	_
	INC, DEC	B/W/L	_
	ADDS, SUBS	L	_
	MULXU, DIVXU, MULXS, DIVXS	B/W	_
	EXTU, EXTS	W/L	_
	TAS* <sup>4</sup>	В	_
Logic operations	AND, OR, XOR, NOT	B/W/L	4
Shift	SHAL, SHAR, SHLL, SHLR, ROTL, ROTR, ROTXL, ROTXR	B/W/L	8
Bit manipulation	BSET, BCLR, BNOT, BTST, BLD, BILD, BST, BIST, BAND, BIAND, BOR, BIOR, BXOR, BIXOR	В	14
Branch	B <sub>cc</sub> *², JMP, BSR, JSR, RTS	_	5
System control	TRAPA, RTE, SLEEP, LDC, STC, ANDC, ORC, XORC, NOP	_	9
Block data transfer	EEPMOV	_	1
			Total: 65

Notes: B: Byte size; W: Word size; L: Longword size.

- POP.W Rn and PUSH.W Rn are identical to MOV.W @SP+, Rn and MOV.W Rn, @-SP. POP.L ERn and PUSH.L ERn are identical to MOV.L @SP+, ERn and MOV.L ERn, @-SP.
- 2.  $B_{cc}$  is the general name for conditional branch instructions.
- 3. Cannot be used in this LSI.
- 4. When using the TAS instruction, use registers ER0, ER1, ER4, and ER5.
- 5. ER7 is not used as the register that can be saved (STM)/restored (LDM) when using STM/LDM instruction, because ER7 is the stack pointer.

# 2.6.1 Table of Instructions Classified by Function

Tables 2.3 to 2.10 summarize the instructions in each functional category. The notation used in tables 2.3 to 2.10 is defined below.

**Table 2.2 Operation Notation** 

Symbol	Description
Rd	General register (destination)*
Rs	General register (source)*
Rn	General register*
ERn	General register (32-bit register)
(EAd)	Destination operand
(EAs)	Source operand
EXR	Extended control register
CCR	Condition-code register
N	N (negative) flag in CCR
Z	Z (zero) flag in CCR
V	V (overflow) flag in CCR
С	C (carry) flag in CCR
PC	Program counter
SP	Stack pointer
#IMM	Immediate data
disp	Displacement
+	Addition
_	Subtraction
×	Multiplication
÷	Division
٨	Logical AND
V	Logical OR
$\oplus$	Logical exclusive OR
$\rightarrow$	Move
~	NOT (logical complement)
:8/:16/:24/:32	8-, 16-, 24-, or 32-bit length

Note: \* General registers include 8-bit registers (R0H to R7H, R0L to R7L), 16-bit registers (R0 to R7, E0 to E7), and 32-bit registers (ER0 to ER7).

**Table 2.3** Data Transfer Instructions

Instruction	Size*1	Function
MOV	B/W/L	(EAs)  o Rd,  Rs  o (EAd)
		Moves data between two general registers or between a general register and memory, or moves immediate data to a general register.
MOVFPE	В	Cannot be used in this LSI.
MOVTPE	В	Cannot be used in this LSI.
POP	W/L	@SP+ → Rn
		Pops a general register from the stack. POP.W Rn is identical to MOV.W @SP+, Rn. POP.L ERn is identical to MOV.L @SP+, ERn
PUSH	W/L	$Rn  o @\operatorname{-SP}$
		Pushes a general register onto the stack. PUSH.W Rn is identical to MOV.W Rn, @-SP. PUSH.L ERn is identical to MOV.L ERn, @-SP.
LDM* <sup>2</sup>	L	@SP+ → Rn (register list)
		Pops two or more general registers from the stack.
STM* <sup>2</sup>	L	Rn (register list) → @-SP
		Pushes two or more general registers onto the stack.

Notes: 1. Size refers to the operand size.

B: Byte W: Word L: Longword

2. ER7 is not used as the register that can be saved (STM)/restored (LDM) when using STM/LDM instruction, because ER7 is the stack pointer.

**Table 2.4** Arithmetic Operations Instructions (1)

Instruction	Size*	Function
ADD	B/W/L	$Rd \pm Rs  o Rd,  Rd \pm \#IMM  o Rd$
SUB		Performs addition or subtraction on data in two general registers, or on immediate data and data in a general register. (Subtraction on immediate data and data in a general register cannot be performed in bytes. Use the SUBX or ADD instruction.)
ADDX	В	$Rd \pm Rs \pm C \rightarrow Rd, Rd \pm \#IMM \pm C \rightarrow Rd$
SUBX		Performs addition or subtraction with carry on data in two general registers, or on immediate data and data in a general register.
INC	B/W/L	$Rd \pm 1 \rightarrow Rd, Rd \pm 2 \rightarrow Rd$
DEC		Adds or subtracts the value 1 or 2 to or from data in a general register. (Only the value 1 can be added to or subtracted from byte operands.)
ADDS	L	$Rd \pm 1 \rightarrow Rd, Rd \pm 2 \rightarrow Rd, Rd \pm 4 \rightarrow Rd$
SUBS		Adds or subtracts the value 1, 2, or 4 to or from data in a 32-bit register.
DAA	В	Rd (decimal adjust) → Rd
DAS		Decimal-adjusts an addition or subtraction result in a general register by referring to CCR to produce 4-bit BCD data.
MULXU	B/W	$Rd \times Rs \rightarrow Rd$
		Performs unsigned multiplication on data in two general registers: either 8 bits $\times$ 8 bits $\rightarrow$ 16 bits or 16 bits $\times$ 16 bits $\rightarrow$ 32 bits.
MULXS	B/W	$Rd \times Rs \rightarrow Rd$
		Performs signed multiplication on data in two general registers: either 8 bits $\times$ 8 bits $\rightarrow$ 16 bits or 16 bits $\times$ 16 bits $\rightarrow$ 32 bits.
DIVXU	B/W	$Rd \div Rs \rightarrow Rd$
		Performs unsigned division on data in two general registers: either 16 bits $\div$ 8 bits $\rightarrow$ 8-bit quotient and 8-bit remainder or 32 bits $\div$ 16 bits $\rightarrow$ 16-bit quotient and 16-bit remainder.

Note: \* Size refers to the operand size.

B: Byte W: Word L: Longword

**Table 2.4** Arithmetic Operations Instructions (2)

Instruction	Size*1	Function
DIVXS	B/W	$Rd \div Rs \rightarrow Rd$
		Performs signed division on data in two general registers: either 16 bits $\div$ 8 bits $\to$ 8-bit quotient and 8-bit remainder or 32 bits $\div$ 16 bits $\to$ 16-bit quotient and 16-bit remainder.
CMP	B/W/L	Rd – Rs, Rd – #IMM
		Compares data in a general register with data in another general register or with immediate data, and sets the CCR bits according to the result.
NEG	B/W/L	$0 - Rd \rightarrow Rd$
		Takes the two's complement (arithmetic complement) of data in a general register.
EXTU	W/L	$Rd \; (zero \; extension) \to Rd$
		Extends the lower 8 bits of a 16-bit register to word size, or the lower 16 bits of a 32-bit register to longword size, by padding with zeros on the left.
EXTS	W/L	Rd (sign extension) $\rightarrow$ Rd
		Extends the lower 8 bits of a 16-bit register to word size, or the lower 16 bits of a 32-bit register to longword size, by extending the sign bit.
TAS*2	В	@ ERd − 0, 1 → ( <bit 7=""> of @ ERd)</bit>
		Tests memory contents, and sets the most significant bit (bit 7) to 1.

Notes: 1. Size refers to the operand size.

B: Byte W: Word L: Longword

2. When using the TAS instruction, use registers ER0, ER1, ER4 and ER5.

**Table 2.5** Logic Operations Instructions

Instruction	Size*	Function
AND	B/W/L	$Rd \land Rs \to Rd,  Rd \land \#IMM \to Rd$
		Performs a logical AND operation on a general register and another general register or immediate data.
OR	B/W/L	$Rd \vee Rs \to Rd,  Rd \vee \#IMM \to Rd$
		Performs a logical OR operation on a general register and another general register or immediate data.
XOR	B/W/L	$Rd \oplus Rs \to Rd,  Rd \oplus \#IMM \to Rd$
		Performs a logical exclusive OR operation on a general register and another general register or immediate data.
NOT	B/W/L	$\sim Rd  o Rd$
		Takes the one's complement (logical complement) of data in a general register.

Note: \* Size refers to the operand size.

B: Byte W: Word L: Longword

**Table 2.6** Shift Instructions

Instruction	Size*	Function
SHAL	B/W/L	$Rd (shift) \rightarrow Rd$
SHAR		Performs an arithmetic shift on data in a general register. 1-bit or 2 bit shift is possible.
SHLL	B/W/L	$Rd (shift) \rightarrow Rd$
SHLR		Performs a logical shift on data in a general register. 1-bit or 2 bit shift is possible.
ROTL	B/W/L	Rd (rotate) $\rightarrow$ Rd
ROTR		Rotates data in a general register. 1-bit or 2 bit rotation is possible.
ROTXL	B/W/L	Rd (rotate) $\rightarrow$ Rd
ROTXR		Rotates data including the carry flag in a general register. 1-bit or 2 bit rotation is possible.

B: Byte W: Word L: Longword

**Table 2.7 Bit Manipulation Instructions (1)** 

Instruction	Size*	Function
BSET	В	$1 \rightarrow (\text{sbit-No.} > \text{of } < \text{EAd} >)$
		Sets a specified bit in a general register or memory operand to 1. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BCLR	В	$0 \rightarrow (\text{sbit-No.} > \text{of } < \text{EAd} >)$
		Clears a specified bit in a general register or memory operand to 0. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BNOT	В	$\sim$ ( <bit-no.> of <ead>) <math>\rightarrow</math> (<bit-no.> of <ead>)</ead></bit-no.></ead></bit-no.>
		Inverts a specified bit in a general register or memory operand. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BTST	В	$\sim$ ( <bit-no.> of <ead>) → Z</ead></bit-no.>
		Tests a specified bit in a general register or memory operand and sets or clears the Z flag accordingly. The bit number is specified by 3-bit immediate data or the lower three bits of a general register.
BAND	В	$C \land (}\ of\ ) \to C$
		Logically ANDs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.
BIAND	В	$C \land (}\ of\ ) \to C$
		Logically ANDs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag.
		The bit number is specified by 3-bit immediate data.
BOR	В	$C \lor ( of <}EAd>) \to C$
		Logically ORs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.
BIOR	В	$C \lor (\sim cbit\text{-No.}>of <\mathsf{EAd}>) \to C$
		Logically ORs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag.
		The bit number is specified by 3-bit immediate data.

B: Byte

**Table 2.7 Bit Manipulation Instructions (2)** 

Instruction	Size*	Function
BXOR	В	$C \oplus (\text{ of }) \rightarrow C$
		Logically exclusive-ORs the carry flag with a specified bit in a general register or memory operand and stores the result in the carry flag.
BIXOR	В	$C \oplus \sim (\text{sbit-No.}\text{> of } \text{}) \to C$
		Logically exclusive-ORs the carry flag with the inverse of a specified bit in a general register or memory operand and stores the result in the carry flag.
		The bit number is specified by 3-bit immediate data.
BLD	В	$($ bit-No. $>$ of <ead<math>&gt;<math>) <math>\rightarrow</math> C</math></ead<math>
		Transfers a specified bit in a general register or memory operand to the carry flag.
BILD	В	$\sim$ ( <bit-no.> of <ead>) → C</ead></bit-no.>
		Transfers the inverse of a specified bit in a general register or memory operand to the carry flag.
		The bit number is specified by 3-bit immediate data.
BST	В	$C \rightarrow (\text{sbit-No.} > \text{of } < \text{EAd} >)$
		Transfers the carry flag value to a specified bit in a general register or memory operand.
BIST	В	$\sim$ C $\rightarrow$ ( <bit-no.>. of <ead>)</ead></bit-no.>
		Transfers the inverse of the carry flag value to a specified bit in a general register or memory operand.
		The bit number is specified by 3-bit immediate data.

B: Byte

**Table 2.8 Branch Instructions** 

# Instruction Size Function Bcc — Branches to a specified address if a specified condition is true. The

branching conditions are listed below.

Mnemonic	Description	Condition
BRA (BT)	Always (true)	Always
BRN (BF)	Never (false)	Never
BHI	High	$C \vee Z = 0$
BLS	Low or same	C ∨ Z = 1
BCC (BHS)	Carry clear	C = 0
	(high or same)	
BCS (BLO)	Carry set (low)	C = 1
BNE	Not equal	Z = 0
BEQ	Equal	Z = 1
BVC	Overflow clear	V = 0
BVS	Overflow set	V = 1
BPL	Plus	N = 0
BMI	Minus	N = 1
BGE	Greater or equal	N ⊕ V = 0
BLT	Less than	N ⊕ V = 1
BGT	Greater than	$Z \vee (N \oplus V) = 0$
BLE	Less or equal	$Z \vee (N \oplus V) = 1$

JMP	_	Branches unconditionally to a specified address.
BSR	_	Branches to a subroutine at a specified address
JSR	_	Branches to a subroutine at a specified address
RTS	_	Returns from a subroutine

**Table 2.9 System Control Instructions** 

Instruction	Size*	Function
TRAPA	_	Starts trap-instruction exception handling.
RTE	_	Returns from an exception-handling routine.
SLEEP		Causes a transition to a power-down state.
LDC	B/W	(EAs)  o CCR, (EAs)  o EXR
		Moves the memory operand contents or immediate data to CCR or EXR. Although CCR and EXR are 8-bit registers, word-size transfers are performed between them and memory. The upper 8 bits are valid.
STC	B/W	CCR  o (EAd),  EXR  o (EAd)
		Transfers CCR or EXR contents to a general register or memory operand. Although CCR and EXR are 8-bit registers, word-size transfers are performed between them and memory. The upper 8 bits are valid.
ANDC	В	$CCR \land \#IMM \rightarrow CCR, EXR \land \#IMM \rightarrow EXR$
		Logically ANDs the CCR or EXR contents with immediate data.
ORC	В	$CCR \lor \#IMM \to CCR,  EXR \lor \#IMM \to EXR$
		Logically ORs the CCR or EXR contents with immediate data.
XORC	В	$CCR \oplus \#IMM \to CCR,  EXR \oplus \#IMM \to EXR$
		Logically exclusive-ORs the CCR or EXR contents with immediate data.
NOP	_	$PC + 2 \rightarrow PC$
		Only increments the program counter.

B: Byte W: Word

Table 2.10 Block Data Transfer Instructions

Instruction	Size	Function
EEPMOV.B	_	if R4L $\neq$ 0 then Repeat @ER5 + $\rightarrow$ @ER6+ R4L-1 $\rightarrow$ R4L Until R4L = 0 else next;
EEPMOV.W	_	if R4 $\neq$ 0 then Repeat @ER5 + $\rightarrow$ @ER6+ R4-1 $\rightarrow$ R4 Until R4 = 0 else next;
		Transfers a data block. Starting from the address set in ER5, transfers data for the number of bytes set in R4L or R4 to the address location set in ER6.
		Execution of the next instruction begins as soon as the transfer is completed.

#### 2.6.2 Basic Instruction Formats

The H8S/2000 CPU instructions consist of 2-byte (1-word) units. An instruction consists of an operation field (op), a register field (r), an effective address extension (EA), and a condition field (cc).

Figure 2.11 shows examples of instruction formats.

#### Operation field

Indicates the function of the instruction, the addressing mode, and the operation to be carried out on the operand. The operation field always includes the first four bits of the instruction. Some instructions have two operation fields.

### · Register field

Specifies a general register. Address registers are specified by 3 bits, and data registers by 3 bits or 4 bits. Some instructions have two register fields, and some have no register field.

- Effective address extension
  - 8, 16, or 32 bits specifying immediate data, an absolute address, or a displacement.
- Condition field

Specifies the branching condition of Bcc instructions.

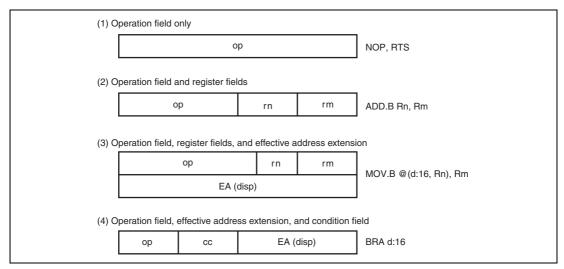

Figure 2.11 Instruction Formats (Examples)

### 2.7 Addressing Modes and Effective Address Calculation

The H8S/2000 CPU supports the eight addressing modes listed in table 2.11. Each instruction uses a subset of these addressing modes.

Arithmetic and logic operations instructions can use the register direct and immediate addressing modes. Data transfer instructions can use all addressing modes except program-counter relative and memory indirect. Bit manipulation instructions can use register direct, register indirect, or absolute addressing mode to specify an operand, and register direct (BSET, BCLR, BNOT, and BTST instructions) or immediate (3-bit) addressing mode to specify a bit number in the operand.

Table 2.11 Addressing Modes

Addressing Mode	Symbol
Register direct	Rn
Register indirect	@ERn
Register indirect with displacement	@(d:16,ERn)/@(d:32,ERn)
Register indirect with post-increment	@ERn+
Register indirect with pre-decrement	@-ERn
Absolute address	@aa:8/@aa:16/@aa:24/@aa:32
Immediate	#xx:8/#xx:16/#xx:32
Program-counter relative	@(d:8,PC)/@(d:16,PC)
Memory indirect	@ @ aa:8
	Register indirect Register indirect with displacement Register indirect with post-increment Register indirect with pre-decrement Absolute address Immediate Program-counter relative

#### 2.7.1 Register Direct—Rn

The register field of the instruction code specifies an 8-, 16-, or 32-bit general register which contains the operand. R0H to R7H and R0L to R7L can be specified as 8-bit registers. R0 to R7 and E0 to E7 can be specified as 16-bit registers. ER0 to ER7 can be specified as 32-bit registers.

### 2.7.2 Register Indirect—@ERn

The register field of the instruction code specifies an address register (ERn) which contains the address of a memory operand. If the address is a program instruction address, the lower 24 bits are valid and the upper 8 bits are all assumed to be 0 (H'00).

### 2.7.3 Register Indirect with Displacement—@(d:16, ERn) or @(d:32, ERn)

A 16-bit or 32-bit displacement contained in the instruction code is added to an address register (ERn) specified by the register field of the instruction, and the sum gives the address of a memory operand. A 16-bit displacement is sign-extended when added.

### 2.7.4 Register Indirect with Post-Increment or Pre-Decrement—@ERn+ or @-ERn

**Register Indirect with Post-Increment**—@**ERn+:** The register field of the instruction code specifies an address register (ERn) which contains the address of a memory operand. After the operand is accessed, 1, 2, or 4 is added to the address register contents and the sum is stored in the

address register. The value added is 1 for byte access, 2 for word access, and 4 for longword access. For word or longword transfer instructions, the register value should be even.

**Register Indirect with Pre-Decrement**—@-**ERn:** The value 1, 2, or 4 is subtracted from an address register (ERn) specified by the register field in the instruction code, and the result becomes the address of a memory operand. The result is also stored in the address register. The value subtracted is 1 for byte access, 2 for word access, and 4 for longword access. For word or longword transfer instructions, the register value should be even.

#### 2.7.5 Absolute Address—@aa:8, @aa:16, @aa:24, or @aa:32

The instruction code contains the absolute address of a memory operand. The absolute address may be 8 bits long (@aa:8), 16 bits long (@aa:16), 24 bits long (@aa:24), or 32 bits long (@aa:32). Table 2.12 indicates the accessible absolute address ranges.

To access data, the absolute address should be 8 bits (@aa:8), 16 bits (@aa:16), or 32 bits (@aa:32) long. For an 8-bit absolute address, the upper 16 bits are all assumed to be 1 (H'FFFF). For a 16-bit absolute address, the upper 16 bits are a sign extension. For a 32-bit absolute address, the entire address space is accessed.

A 24-bit absolute address (@aa:24) indicates the address of a program instruction. The upper 8 bits are all assumed to be 0 (H'00).

Table 2.12 Absolute Address Access Ranges

Absolute Address		Normal Mode	Advanced Mode
Data address	8 bits (@aa:8)	H'FF00 to H'FFFF	H'FFFF00 to H'FFFFFF
	16 bits (@aa:16)	H'0000 to H'FFFF	H'000000 to H'007FFF, H'FF8000 to H'FFFFFF
	32 bits (@aa:32)	<del></del>	H'000000 to H'FFFFF
Program instruction address	24 bits (@aa:24)	_	

#### 2.7.6 Immediate—#xx:8, #xx:16, or #xx:32

The 8-bit (#xx:8), 16-bit (#xx:16), or 32-bit (#xx:32) immediate data contained in an instruction code can be used directly as an operand.

The ADDS, SUBS, INC, and DEC instructions implicitly contain immediate data in their instruction codes. Some bit manipulation instructions contain 3-bit immediate data in the instruction code, specifying a bit number. The TRAPA instruction contains 2-bit immediate data in its instruction code, specifying a vector address.

#### 2.7.7 Program-Counter Relative—@(d:8, PC) or @(d:16, PC)

This mode can be used by the Bcc and BSR instructions. An 8-bit or 16-bit displacement contained in the instruction code is sign-extended to 24 bits and added to the 24-bit address indicated by the PC value to generate a 24-bit branch address. Only the lower 24 bits of this branch address are valid; the upper 8 bits are all assumed to be 0 (H'00). The PC value to which the displacement is added is the address of the first byte of the next instruction, so the possible branching range is -126 to +128 bytes (-63 to +64 words) or -32766 to +32768 bytes (-16383 to +16384 words) from the branch instruction. The resulting value should be an even number.

#### 2.7.8 Memory Indirect—@@aa:8

This mode can be used by the JMP and JSR instructions. The instruction code contains an 8-bit absolute address specifying a memory operand which contains a branch address. The upper bits of the 8-bit absolute address are all assumed to be 0, so the address range is 0 to 255 (H'0000 to H'00FF in normal mode, H'000000 to H'000FF in advanced mode).

In normal mode, the memory operand is a word operand and the branch address is 16 bits long. In advanced mode, the memory operand is a longword operand, the first byte of which is assumed to be 0 (H'00). Note that the top area of the address range in which the branch address is stored is also used for the exception vector area. For further details, refer to section 4, Exception Handling.

If an odd address is specified in word or longword memory access, or as a branch address, the least significant bit is regarded as 0, causing data to be accessed or the instruction code to be fetched at the address preceding the specified address. (For further information, see section 2.5.2, Memory Data Formats.)

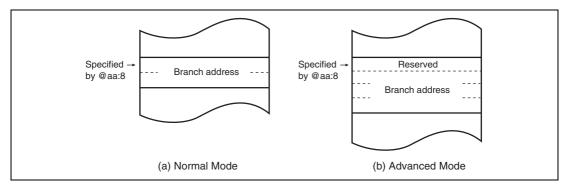

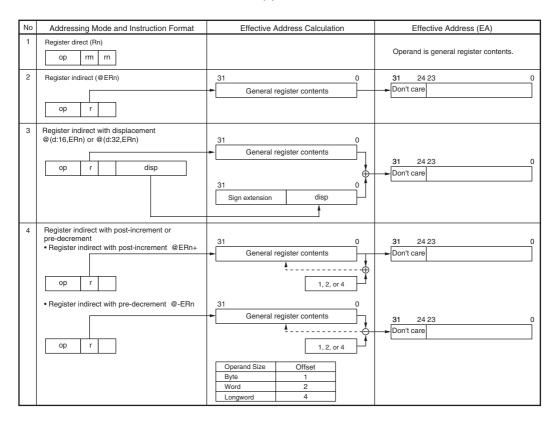

Figure 2.12 Branch Address Specification in Memory Indirect Addressing Mode

#### 2.7.9 Effective Address Calculation

Table 2.13 indicates how effective addresses are calculated in each addressing mode. In normal mode, the upper 8 bits of the effective address are ignored in order to generate a 16-bit address.

Table 2.13 Effective Address Calculation (1)

**Table 2.13 Effective Address Calculation (2)** 

No	Addressing Mode and Instruction Format	Effective Address Calculation	Effective Address (EA)
5	Absolute address		
	@aa:8		<b>31</b> 24 23 8 7 0

### 2.8 Processing States

The H8S/2000 CPU has four main processing states: the reset state, exception handling state, program execution state, and program stop state. Figure 2.13 indicates the state transitions.

#### Reset state

In this state the CPU and on-chip peripheral modules are all initialized and stopped. When the  $\overline{RES}$  input goes low, all current processing stops and the CPU enters the reset state. All interrupts are masked in the reset state. Reset exception handling starts when the  $\overline{RES}$  signal changes from low to high. For details, refer to section 4, Exception Handling.

The reset state can also be entered by a watchdog timer overflow.

#### • Exception-handling state

The exception-handling state is a transient state that occurs when the CPU alters the normal processing flow due to an exception source, such as, a reset, trace, interrupt, or trap instruction. The CPU fetches a start address (vector) from the exception vector table and branches to that address. For further details, refer to section 4, Exception Handling.

### • Program execution state

In this state the CPU executes program instructions in sequence.

#### • Program stop state

This is a power-down state in which the CPU stops operating. The program stop state occurs when a SLEEP instruction is executed or the CPU enters hardware standby mode. For details, refer to section 18, Power-Down Modes.

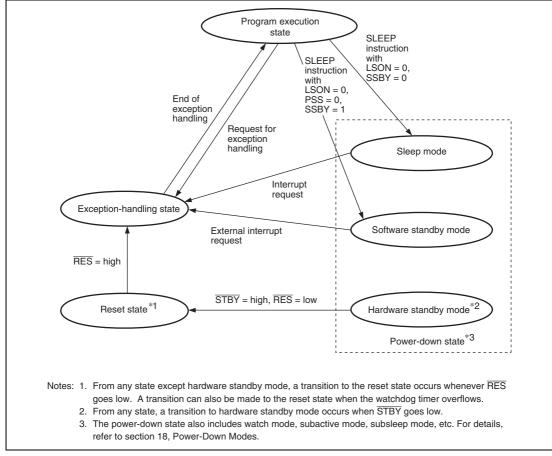

Figure 2.13 State Transitions

### 2.9 Usage Notes

#### 2.9.1 Note on TAS Instruction Usage

When using the TAS instruction, use registers ER0, ER1, ER4 and ER5.

The TAS instruction is not generated in the H8S, H8/300 Series C/C++ Compiler by Renesas Technology Corp. When the TAS instruction is used as a user-defined intrinsic function, use registers ER0, ER1, ER4 and ER5.

#### 2.9.2 Note on STM/LDM Instruction Usage

ER7 is not used as the register that can be saved (STM)/restored (LDM) when using STM/LDM instruction, because ER7 is the stack pointer. Two, three, or four registers can be saved/restored by one STM/LDM instruction. The following ranges can be specified in the register list.

Two registers: ER0—ER1, ER2—ER3, or ER4—ER5

Three registers: ER0—ER2 or ER4—ER6

Four registers: ER0—ER3

The STM/LDM instruction including ER7 is not generated by the H8S, H8/300 Series C/C++ Compiler by Renesas Technology Corp.

### 2.9.3 Note on Bit Manipulation Instructions

The BSET, BCLR, BNOT, BST, and BIST instructions read data from the specified address in byte units, manipulate the data of the target bit, and write data to the same address again in byte units. Special care is required when using these instructions in cases where a register containing a write-only bit is used or a bit is directly manipulated for a port, because this may rewrite data of a bit other than the bit to be manipulated.

**Example:** The BCLR instruction is executed for DDR in port 4.

P47 and P46 are input pins, with a low-level signal input at P47 and a high-level signal input at P46. P45 to P40 are output pins and output low-level signals. The following shows an example in which P40 is set to be an input pin with the BCLR instruction.

#### Prior to executing BCLR:

	P47	P46	P45	P44	P43	P42	P41	P40
Input/output	Input	Input	Output	Output	Output	Output	Output	Output
Pin state	Low level	High level	Low level	Low level	Low level	Low level	Low level	Low level
DDR	0	0	1	1	1	1	1	1
DR	1	0	0	0	0	0	0	0

#### **BCLR** instruction executed:

BCLR #0, @P4DDR The BCLR instruction is executed for DDR in po
--

#### After executing BCLR:

	P47	P46	P45	P44	P43	P42	P41	P40
Input/output	Output	Output	Output	Output	Output	Output	Output	Input
Pin state	Low level	High level	Low level	Low level	Low level	Low level	Low level	High level
DDR	1	1	1	1	1	1	1	0
DR	1	0	0	0	0	0	0	0

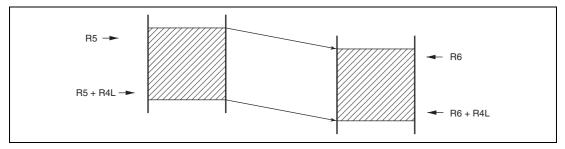

### **Operation:**

- When the BCLR instruction is executed, first the CPU reads P4DDR.
   Since P4DDR is a write-only register, so the CPU reads H'FF. In this example P4DDR has a value of H'3F, but the value read by the CPU is H'FF.
- 2. The CPU clears bit 0 of the read data to 0, changing data to H'FE.
- 3. The CPU writes H'FE to DDR, completing execution of BCLR.

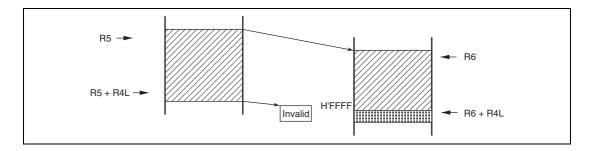

As a result of the BCLR instruction, bit 0 in DDR is set to 0, and P40 becomes an input pin. However, bits 7 and 6 of DDR are modified to 1, therefore P47 and P46 become output pins.

#### 2.9.4 EEPMOV Instruction

1. EEPMOV is a block-transfer instruction and transfers the byte size of data indicated by R4L, which starts from the address indicated by R5, to the address indicated by R6.

2. Set R4L and R6 so that the end address of the destination address (value of R6 + R4L) does not exceed H'FFFF (the value of R6 must not change from H'FFFF to H'0000 during execution).

## Section 3 MCU Operating Modes

### 3.1 MCU Operating Mode Selection

This LSI has three operating modes (modes 1 to 3). The operating mode is determined by the setting of the mode pins (MD1 and MD0). Table 3.1 shows the MCU operating mode selection.

Table 3.1 lists the MCU operating modes.

**Table 3.1 MCU Operating Mode Selection** 

MCU Operating Mode	MD1	MD0	CPU Operating Mode	Description	On-Chip ROM
0	0	0	_	_	_
1	_	1	Normal	Expanded mode with on-chip ROM disabled	Disabled
2	1	0	Advanced	Expanded mode with on-chip ROM enabled	Enabled
				Single-chip mode	
3	_	1	Normal	Expanded mode with on-chip ROM enabled	_
				Single-chip mode	

Mode 1 is an expanded mode that allows access to external memory and peripheral devices. With modes 2 and 3, operation begins in single-chip mode after reset release, but a transition can be made to external expansion mode by setting the EXPE bit in MDCR to 1.

Mode 0 cannot be used in this LSI. Thus, mode pins should be set to enable mode 1, 2 or 3 in normal program execution state. Mode pins should not be changed during operation.

### 3.2 Register Descriptions

The following registers are related to the operating mode. For details on the bus control register (BCR), refer to section 6.3.1, Bus Control Register (BCR).

- Mode control register (MDCR)
- System control register (SYSCR)
- Serial timer control register (STCR)

### 3.2.1 Mode Control Register (MDCR)

MDCR is used to set an operating mode and to monitor the current operating mode.

Bit	Bit Name	Initial Value	R/W	Description
7	EXPE	*	R/W*	Extended Mode Enable
				Specifies extended mode. Fixed to 1 and cannot be modified in mode 1. Readable/writable and the initial value is 0 in mode 2 or 3.
				0: Single-chip mode
				1: Extended mode
6	_	All 0	R	Reserved
to 2				These bits are always read as 0. These bits cannot be modified.
1	MDS1	*	R	Mode Select 1 and 0
0	MDS0	<u></u> *	R	These bits indicate the input levels at mode pins (MD1 and MD0) (the current operating mode). Bits MDS1 and MDS0 correspond to MD1 and MD0, respectively. These bits are read-only bits and they cannot be written to. The mode pin (MD1 and MD0) input levels are latched into these bits when MDCR is read. These latches are canceled by a reset.

Note: \* The initial values are determined by the settings of the MD1 and MD0 pins.

### 3.2.2 System Control Register (SYSCR)

SYSCR selects a system pin function, monitors a reset source, selects the interrupt control mode and the detection edge for NMI, pin location selection, enables or disables register access to the on-chip peripheral modules, and enables or disables on-chip RAM address space.

Bit	Bit Name	Initial Value	R/W	Description
7	_	0	R/W	Reserved
				Although this bit is readable or writable, do not set to 1.
6	IOSE	0	R/W	IOS Enable
				Enables or disables $\overline{\text{AS}}/\overline{\text{IOS}}$ pin function in extended mode.
				0: AS pin Outputs low when an external area is accessed.
				1: <del>IOS</del> pin Outputs low when a specified address of addresses H'(FF)F000 to H'(FF)F7FF is accessed.
5	INTM1	0	R	Interrupt Control Select Mode 1 and 0
4	INTM0	0	R/W	These bits select the control mode of the interrupt controller. For details on the interrupt control modes and interrupt control select modes 1 and 0, see section 5.6, Interrupt Control Modes and Interrupt Operation.
				00: Interrupt control mode 0
				01: Interrupt control mode 1
				10: Setting prohibited
				11: Setting prohibited
3	XRST	1	R	External Reset
				This bit indicates the reset source. A reset is caused by an external reset input, or when the watchdog timer overflows.
				0: A reset is caused when the watchdog timer overflows.
				1: A reset is caused by an external reset.

Bit	Bit Name	Initial Value	R/W	Description
2	NMIEG	0	R/W	NMI Edge Select
				Selects the valid edge of the NMI interrupt input.
				0: An interrupt is requested at the falling edge of NMI input
				1: An interrupt is requested at the rising edge of NMI input
1	HIE	0	R/W	Host Interface Enable
				Controls the CPU access to the keyboard matrix interrupt and input pull-up MOS control registers (KMIMR, KMPCR, and KMIMRA), and the 8-bit timer (TMR_Y) registers (TCR_Y, TCSR_Y, TCORA_Y, TCORB_Y, TCNT_Y, and TISR).
				<ol> <li>TMR_Y registers are accessed through an area from H'(FF)FFF0 to H'(FF)FFF7 and an area from H'(FF)FFFC to H'(FF)FFFF</li> </ol>
				<ol> <li>Keyboard matrix interrupt and input pull-up MOS control registers are accessed through an area from H'(FF)FFF0 to H'(FF)FFF7 and an area from H'(FF)FFFC to H'(FF)FFFF</li> </ol>
0	RAME	1	R/W	RAM Enable
				Enables or disables on-chip RAM. The RAME bit is initialized when the reset state is released.
				0: On-chip RAM is disabled
				1: On-chip RAM is enabled

### 3.2.3 Serial Timer Control Register (STCR)

STCR enables or disables register access and on-chip flash memory, and selects the input clock of the timer counter.

Bit	Bit Name	Initial Value	R/W	Description
7	IICS*	0	R/W	I <sup>2</sup> C Extra Buffer Select
				Specifies bits 7 to 4 of port A as open-drain output buffers. These pins are used to implement an I <sup>2</sup> C interface only by software.
				0: PA7 to PA4 are normal input/output pins.
				<ol> <li>PA7 to PA4 are input/output pins enabling bus driving.</li> </ol>
6, 5	_	All 0	R/W	Reserved
				These bits should not be changed.
4	IICE	0	R/W	I <sup>2</sup> C Master Enable
				Enables or disables the CPU access to the PWMX registers (DADRAH/DACR, DADRAL, DADRBH/DACNTH, DADRBL/DACNTL), and SCI registers (SMR, BRR, SCMR).
				<ol> <li>SCI_1 registers are accessed through an area from H'(FF)FF88 to H'(FF)FF89 and an area from H'(FF)FF8E to H'(FF)FF8F.</li> </ol>
				SCI_2 registers are accessed through an area from H'(FF)FFA0 to H9'(FF)FFA1 and an area from H'(FF)FFA6 to H'(FF)FFA7.
				SCI_0 registers are accessed through an area from H'(FF)FFD8 to H'(FF)FFD9 and an area from H'(FF)FFDE to H'(FF)FFDF.
				<ol> <li>No are accessed through an area from H'(FF)FF88 to H'(FF)FF89 and an area from H'(FF)FF8E to H'(FF)FF8F.</li> </ol>
				PWMX registers are accessed through an area from H'(FF)FFA0 to H'(FF)FFA1 and an area from H'(FF)FFA6 to H'(FF)FFA7.
				No registers are accessed through an area from H'(FF)FFD8 to H'(FF)FFD9 and through an area from H'(FF)FFDE to H'(FF)FFDF.

Bit	Bit Name	Initial Value	R/W	Description
3	FLSHE	0	R/W	Flash Memory Control Register Enable
				Enables or disables CPU access for flash memory registers (FLMCR1, FLMCR2, EBR1, EBR2), control registers in power-down state (SBYCR, LPWRCR, MSTPCRH, MSTPCRL), and control registers of onchip peripheral modules (PCSR, SYSCR2).
				0: Registers in power-down state and control registers of on-chip peripheral modules are accessed in an area from H'(FF)FF80 to H'(FF)FF87.
				1: Control registers of flash memory are accessed in an area from H'(FF)FF80 to H'(FF)FF87.
2	_	0	R/(W)	Reserved
				The initial value should not be changed.
1	ICKS1	0	R/W	Internal Clock Source Select 1, 0
0	ICKS0	0	R/W	These bits select a clock to be input to the timer counter (TCNT) and a count condition together with bits CKS2 to CKS0 in the timer control register (TCR). For details, refer to section 10.3.4, Timer Control Register (TCR).

Note: \* Available only for the H8S/2144B.

### 3.3 Operating Mode Descriptions

#### 3.3.1 Mode 1

The CPU can access a 64-kbyte address space in normal mode. The on-chip ROM is disabled.

Ports 1 and 2 function as an address bus, port 3 functions as a data bus, and part of port 9 carries bus control signals. Clearing the ABW bit to 0 in the WSCR register makes port B a data bus.

#### 3.3.2 Mode 2

The CPU can access a 16-Mbyte address space in advanced mode. The on-chip ROM is enabled.

After a reset, the LSI is set to single-chip mode. To access an external address space, bit EXPE in MDCR should be set to 1.

When the EXPE bit in MDCR is set to 1, ports 1, 2 and A function as input ports after a reset. Ports 1, 2 and A output an address by setting 1 to the corresponding port data direction register (DDR). Port 3 functions as a data bus, and parts of port 9 carry bus control signals. Port B functions as a data bus when the ABW bit in WSCR is cleared to 0.

#### 3.3.3 Mode 3

The CPU can access a 64-kbyte address space in normal mode. The on-chip ROM is enabled. The CPU can access a 56-kbyte address space in mode 3.

After a reset, the LSI is set to single-chip mode. To access an external address space, bit EXPE in MDCR should be set to 1.

When the EXPE bit in MDCR is set to 1, ports 1 and 2 function as input ports after a reset. Ports 1 and 2 function as an address bus by setting 1 to the corresponding port data direction register (DDR). Port 3 functions as a data bus, and parts of port 9 carry bus control signals. Port B functions as a data bus when the ABW bit in WSCR is cleared to 0.

### 3.3.4 Pin Functions in Each Operating Mode

Pin functions of ports 1 to 3, 9, A, and B depend on the operating mode. Table 3.2 shows pin functions in each operating mode.

**Table 3.2 Pin Functions in Each Mode** 

Port		Mode 1	Mode 2	Mode 3	
Port 1		Α	P* <sup>1</sup> /A	P* <sup>1</sup> /A	
Port 2		Α	P* <sup>1</sup> /A	P*1/A	
Port A*2		Р	P* <sup>1</sup> /A	Р	
Port 3		D	P*¹/D	P*¹/D	
Port B*2		P*¹/D	P*¹/D	P*¹/D	
Port 9	P97	P*¹/C	P*¹/C	P*¹/C	
	P96	C*1/P	P*¹/C	P*¹/C	
	P95 to P93	С	P*¹/C	P*¹/C	
	P92 to P91	Р	Р	Р	
	P90	P*¹/C	P*¹/C	P*¹/C	

### [Legend]

P: I/O port

A: Address bus output

D: Data bus I/O

C: Control signals, clock I/O

Notes: 1. Immediately after a reset.

2. Available only for the H8S/2144B.

### 3.4 Address Map in Each Operating Mode

Figures 3.1 and 3.2 show the address map in each operating mode.

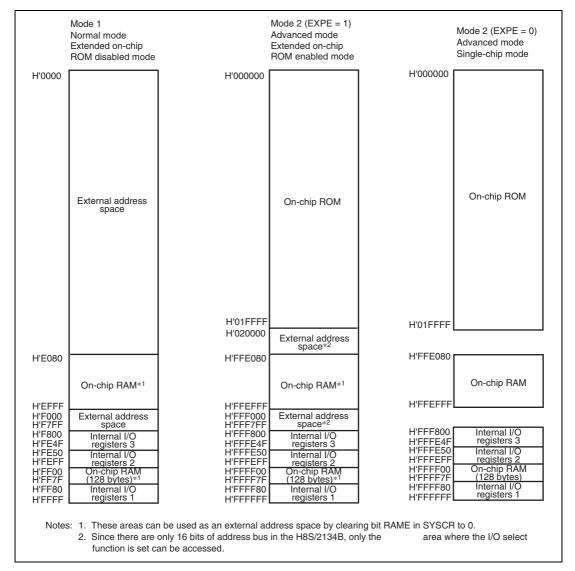

Figure 3.1 Address Map (1)

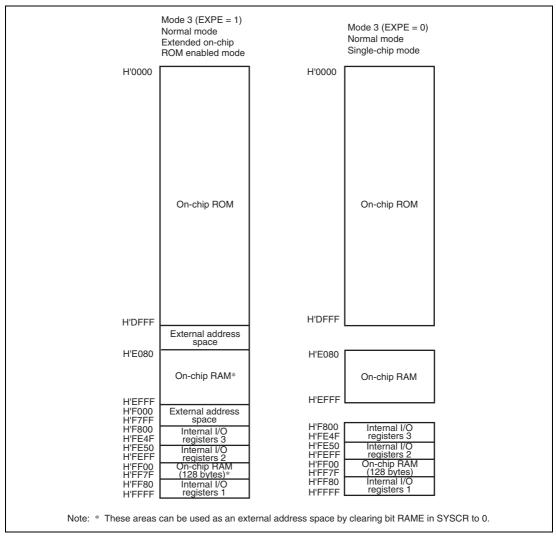

Figure 3.2 Address Map (2)

# Section 4 Exception Handling

### 4.1 Exception Handling Types and Priority

Exception handling is caused by a reset, interrupt, direct transition, or trap instruction as shown in table 4.1. Exception handling is prioritized as shown in table 4.1. If two or more exceptions occur simultaneously, they are accepted and processed in order of priority.

**Table 4.1** Exception Types and Priority

Priority	<b>Exception Type</b>	Start of Exception Handling
High	Reset	Starts immediately after the signal level on the RES pin changes from low to high or when the watchdog timer overflows.
	Interrupt	Starts when execution of the current instruction or exception handling ends, if an interrupt request has been issued. Interrupt detection is not performed on completion of ANDC, ORC, XORC, or LDC instruction execution, or on completion of reset exception handling.
	Direct transition	Starts when a direct transition occurs as the result of SLEEP instruction execution.
Low	Trap instruction	Started by execution of a trap (TRAPA) instruction. Trap instruction exception handling requests are accepted at all times in program execution state.

**Exception Source**

Internal interrupt\*

#### 4.3 Reset

The reset exception handling is given the highest priority. When the  $\overline{RES}$  signal goes low, all processing halts and this LSI enters the reset state. When the power is turned on, hold the  $\overline{RES}$  signal low for at least 20 ms to ensure that this LSI is reset. To reset this LSI during operation, hold the  $\overline{RES}$  signal low for at least 20 cycles. A reset initializes the internal state of the CPU and the registers of on-chip peripheral modules. This LSI can also be reset by an overflow of the watchdog timer. For details, see section 11, Watchdog Timer (WDT).

#### 4.3.1 Reset Exception Handling

When the RES signal goes high after being held low for a given time, this LSI starts the reset exception handling as follows:

- 1. The internal state of the CPU and the registers of the on-chip peripheral modules are initialized and the I bit is set to 1 in CCR.
- 2. The vector address of the reset exception handling is read and transferred to the PC, and program execution starts from the address indicated by the PC.

Figure 4.1 shows an example of the reset sequence.

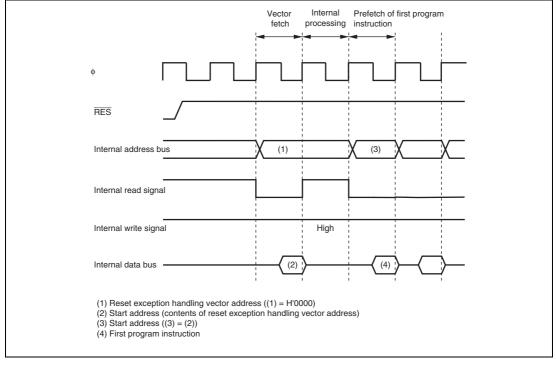

Figure 4.1 Reset Sequence (Mode 3)

### 4.3.2 Interrupts after Reset

If an interrupt is accepted after a reset and before the stack pointer (SP) is initialized, the PC and CCR will not be saved correctly, leading to a program crash. To prevent this, all interrupt requests, including NMI, are disabled immediately after a reset. Since the first instruction of a program is always executed immediately after the reset state ends, make sure that this instruction initializes the stack pointer (example: MOV.L #xx: 32, SP).

### 4.3.3 On-Chip Peripheral Modules after Reset is Released

After a reset is released, the module stop control registers (MSTPCR) are initialized, and all modules are in module stop mode. Therefore, the registers of on-chip peripheral modules cannot be read from or written to. To read from and write to these registers, leave the module stop mode.

### 4.4 Interrupt Exception Handling

Interrupts are controlled by the interrupt controller. The sources to start interrupt exception handling are external interrupt sources (NMI, IRQ7 to IRQ0, and KIN15 to KIN0) and internal interrupt sources from the on-chip peripheral modules. NMI is an interrupt with the highest priority. For details, refer to section 5, Interrupt Controller.

Interrupt exception handling is conducted as follows:

- 1. The values in the program counter (PC) and condition code register (CCR) are saved to the stack.
- 2. A vector address corresponding to the interrupt source is generated, the start address is loaded from the vector table to the PC, and program execution begins from that address.

### 4.5 Trap Instruction Exception Handling

Trap instruction exception handling starts when a TRAPA instruction is executed. Trap instruction exception handling can be executed at all times in the program execution state.

Trap instruction exception handling is conducted as follows:

- 1. The values in the program counter (PC) and condition code register (CCR) are saved to the stack.
- 2. A vector address corresponding to the interrupt source is generated, the start address is loaded from the vector table to the PC, and program execution starts from that address.

The TRAPA instruction fetches a start address from a vector table entry corresponding to a vector number from 0 to 3, as specified in the instruction code.

Table 4.3 shows the status of CCR after execution of trap instruction exception handling.

Table 4.3 Status of CCR after Trap Instruction Exception Handling

		CCR	
Interrupt Control Mode	Ī	UI	
0	1	_	
1	1	1	

#### [Legend]

1: Set to 1

—: Retains value prior to execution

### 4.6 Stack Status after Exception Handling

Figure 4.2 shows the stack after completion of trap instruction exception handling and interrupt exception handling.

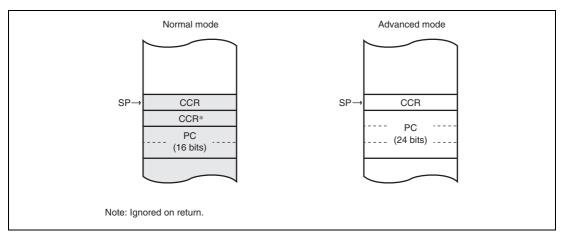

Figure 4.2 Stack Status after Exception Handling

### 4.7 Usage Note

When accessing word data or longword data, this LSI assumes that the lowest address bit is 0. The stack should always be accessed in words or longwords, and the value of the stack pointer (SP: ER7) should always be kept even.

Use the following instructions to save registers:

```
PUSH.W Rn (or MOV.W Rn, @-SP)

PUSH.L ERn (or MOV.L ERn, @-SP)
```

Use the following instructions to restore registers:

```
POP.W Rn (or MOV.W @SP+, Rn)
POP.L ERn (or MOV.L @SP+, ERn)
```

Setting SP to an odd value may lead to a malfunction. Figure 4.3 shows an example of what happens when the SP value is odd.

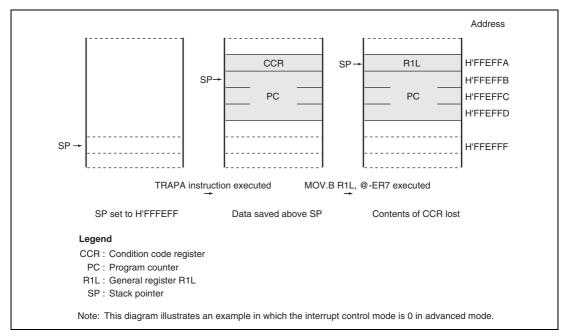

Figure 4.3 Operation when SP Value is Odd

# Section 5 Interrupt Controller

#### 5.1 Features

• Two interrupt control modes

Any of two interrupt control modes can be set by means of the INTM1 and INTM0 bits in the system control register (SYSCR).

Priorities settable with ICR

An interrupt control register (ICR) is provided for setting interrupt priorities. Three priority levels can be set for each module for all interrupts except NMI and address break.

• Independent vector addresses

All interrupt sources are assigned independent vector addresses, making it unnecessary for the source to be identified in the interrupt handling routine.

• 23 external interrupts

NMI is the highest-priority interrupt, and is accepted at all times. Rising edge or falling edge detection can be selected for NMI. Falling-edge, rising-edge, or both-edge detection, or level sensing, can be selected for  $\overline{IRQ7}$  to  $\overline{IRQ0}$ . The IRQ6 interrupt is shared by the interrupt from the  $\overline{IRQ6}$  pin and eight external interrupt inputs ( $\overline{KIN7}$  to  $\overline{KIN0}$ ), and the IRQ7 interrupt is shared by the interrupt from the  $\overline{IRQ7}$  pin and sixteen external interrupt inputs ( $\overline{KIN15}$  to  $\overline{KIN15}$  to  $\overline{KIN0}$  can be masked individually by the user program.

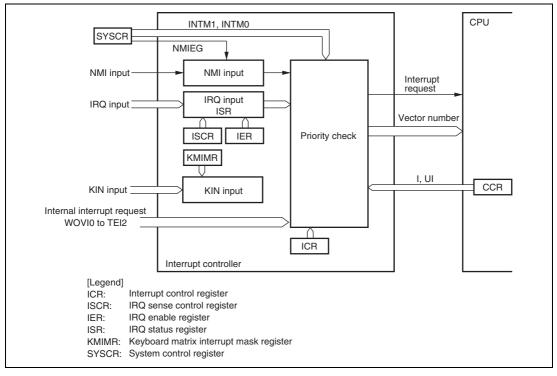

Figure 5.1 Block Diagram of Interrupt Controller

## 5.2 Input/Output Pins

Table 5.1 summarizes the pins of the interrupt controller.

**Table 5.1** Pin Configuration

Symbol	I/O	Function	
NMI	Input	Nonmaskable external interrupt	
		Rising edge or falling edge can be selected	
IRQ7 to IRQ0	Input	Maskable external interrupts	
		Rising edge, falling edge, or both edges, or level sensing, can be selected individually for each pin.	
KIN15 to KIN0	Input	Maskable external interrupts	
(KIN7 to KIN0)*		Falling edge or level sensing can be selected.	

Note: \* H8S/2134B

# **5.3** Register Descriptions

The interrupt controller has the following registers. For details on the system control register (SYSCR), refer to section 3.2.2, System Control Register (SYSCR).

- Interrupt control registers A to C (ICRA to ICRC)
- Address break control register (ABRKCR)
- Break address registers A to C (BARA to BARC)
- IRQ sense control registers (ISCRH, ISCRL)
- IRQ enable register (IER)
- IRQ status register (ISR)
- Keyboard matrix interrupt mask registers (KMIMRA, KMIMR)

## 5.3.1 Interrupt Control Registers A to C (ICRA to ICRC)

The ICR registers set interrupt control levels for interrupts other than NMI and address breaks.

The correspondence between interrupt sources and ICRA to ICRC settings is shown in table 5.2.

Bit	Bit Name	Initial Value	R/W	Description
7	ICRn7	All 0	R/W	Interrupt Control Level
to 0	to IRCn0			Corresponding interrupt source is interrupt control level 0 (no priority)
				Corresponding interrupt source is interrupt control level 1 (priority)

n: A to C

Table 5.2 Correspondence between Interrupt Source and ICR

			Register	
Bit	Bit Name	ICRA	ICRB	ICRC
7	ICRn7	IRQ0	A/D converter	SCI_0
6	ICRn6	IRQ1	FRT	SCI_1
5	ICRn5	IRQ2, IRQ3	_	SCI_2
4	ICRn4	IRQ4, IRQ5	_	_
3	ICRn3	IRQ6, IRQ7	TMR_0	_
2	ICRn2	_	TMR_1	_
1	ICRn1	WDT_0	TMR_Y	_
0	ICRn0	WDT_1	_	_
	4 : 0			

n: A to C

—: Reserved. The write value should always be 0.

### 5.3.2 Address Break Control Register (ABRKCR)

ABRKCR controls the address breaks. When both the CMF flag and BIE flag are set to 1, an address break is requested.

Bit	Bit Name	Initial Value	R/W	Description
7	CMF	0	R	Condition Match Flag
				Address break source flag. Indicates that an address specified by BARA to BARC is prefetched.
				[Setting condition]
				When an address specified by BARA to BARC is prefetched while the BIE flag is set to 1.
				[Clearing condition]
				When an exception handling is executed for an address break interrupt.
6	_	All 0	R	Reserved
to 1				These bits are always read as 0 and cannot be modified.
0	BIE	0	R/W	Break Interrupt Enable
				Enables or disables address break.
				0: Disabled
				1: Enabled

# 5.3.3 Break Address Registers A to C (BARA to BARC)

The BAR registers specify an address that is to be a break address. An address in which the first byte of an instruction exists should be set as a break address. In normal mode, addresses A23 to A16 are not compared.

#### BARA

Bit	Bit Name	Initial Value	R/W	Description
7	A23	All 0	R/W	Addresses 23 to 16
to 0	to A16			The A23 to A16 bits are compared with A23 to A16 in the internal address bus.

### • BARB

Bit	Bit Name	Initial Value	R/W	Description
7	A15	All 0	R/W	Addresses 15 to 8
to 0	to A8			The A15 to A8 bits are compared with A15 to A8 in the internal address bus.

## BARC

Bit	Bit Name	Initial Value	R/W	Description
7	A7	All 0	R/W	Addresses 7 to 1
to 1	to A1			The A7 to A1 bits are compared with A7 to A1 in the internal address bus.
0	_	0	R	Reserved
				This bit is always read as 0 and cannot be modified.

# 5.3.4 IRQ Sense Control Registers (ISCRH, ISCRL)

The ISCR registers select the source that generates an interrupt request at pins  $\overline{IRQ7}$  to  $\overline{IRQ0}$ .

## ISCRH

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ7SCB	0	R/W	IRQn Sense Control B
6	IRQ7SCA	0	R/W	IRQn Sense Control A
5	IRQ6SCB	0	R/W	00: Interrupt request generated at low level of
4	IRQ6SCA	0	R/W	ĪRQn input
3	IRQ5SCB	0	R/W	01: Interrupt request generated at falling edge of IRQn input
2	IRQ5SCA	0	R/W	10: Interrupt request generated at rising edge
1	IRQ4SCB	0	R/W	of IRQn input
0	IRQ4SCA	0	R/W	<ol> <li>Interrupt request generated at both falling and rising edges of IRQn input</li> </ol>
				(n = 7 to 4)

### • ISCRL

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ3SCB	0	R/W	IRQn Sense Control B
6	IRQ3SCA	0	R/W	IRQn Sense Control A
5	IRQ2SCB	0	R/W	00: Interrupt request generated at low level of
4	IRQ2SCA	0	R/W	IRQn input
3	IRQ1SCB	0	R/W	<ul> <li>01: Interrupt request generated at falling edge of IRQn input</li> </ul>
2	IRQ1SCA	0	R/W	10: Interrupt request generated at rising edge
1	IRQ0SCB	0	R/W	of IRQn input
0	IRQ0SCA	0	R/W	<ol> <li>Interrupt request generated at both falling and rising edges of IRQn input</li> </ol>
				(n = 3 to 0)

# 5.3.5 IRQ Enable Register (IER)

IER controls the enabling and disabling of interrupt requests IRQ7 to IRQ0.

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ7E	0	R/W	IRQn Enable (n = 7 to 0)
6	IRQ6E	0	R/W	The IRQn interrupt request is enabled when
5	IRQ5E	0	R/W	this bit is 1.
4	IRQ4E	0	R/W	
3	IRQ3E	0	R/W	
2	IRQ2E	0	R/W	
1	IRQ1E	0	R/W	
0	IRQ0E	0	R/W	

# 5.3.6 IRQ Status Register (ISR)

The ISR register is a flag register that indicates the status of IRQ7 to IRQ0 interrupt requests.

Bit	Bit Name	Initial Value	R/W	Description
7	IRQ7F	0	R/(W)*	[Setting condition]
6	IRQ6F	0	R/(W)*	When the interrupt source selected by the
5	IRQ5F	0	R/(W)*	ISCR registers occurs
4	IRQ4F	0	R/(W)*	[Clearing conditions]
3	IRQ3F	0	R/(W)*	When reading IRQnF flag when IRQnF =
2	IRQ2F	0	R/(W)*	1, then writing 0 to IRQnF flag
1	IRQ1F	0	R/(W)*	When interrupt exception handling is
0	IRQ0F	0	R/(W)*	executed when low-level detection is set and $\overline{IRQn}$ input is high (n = 7 to 0)
				<ul> <li>When IRQn interrupt exception handling is executed when falling-edge, rising-edge, or both-edge detection is set</li> </ul>

Note: \* Only 0 can be written, for flag clearing.

### 5.3.7 Keyboard Matrix Interrupt Mask Registers (KMIMRA, KMIMR)

KMIMRA and KMIMR mask each key-sensing input ( $\overline{\text{KIN}15}$  to  $\overline{\text{KIN}0}$ ) interrupt. To make the settings of these registers valid, clear bit MSTP2 in MSTPCRL to 0.

#### KMIMRA

Bit	Bit Name	Initial Value	R/W	Description
7	KMIMR15	1	R/W	Keyboard Matrix Interrupt Mask 15 to 8
6	KMIMR14	1	R/W	These bits enable or disable a key-sensing
5	KMIMR13	1	R/W	input interrupt request (KIN15 to KIN8).
4	KMIMR12	1	R/W	0: Enables a key-sensing input interrupt request
3	KMIMR11	1	R/W	1: Disables a key-sensing input interrupt
2	KMIMR10	1	R/W	request
1	KMIMR9	1	R/W	
0	KMIMR8	1	R/W	

Note: Bits KMIMR15 to KMIMR8 should not be cleared to 0 in the H8S/2134B.

#### KMIMR

Bit	Bit Name	Initial Value	R/W	Description
7	KMIMR7	1	R/W	Keyboard Matrix Interrupt Mask 7 to 0
6	KMIMR6	0	R/W	These bits enable or disable a key-sensing
5	KMIMR5	1	R/W	input interrupt request (KIN7 to KIN0).
4	KMIMR4	1	R/W	KMIMR6 also performs interrupt request mask
3	KMIMR3	1	R/W	control for pin IRQ6.
2	KMIMR2	1	R/W	0: Enables a key-sensing input interrupt request
1	KMIMR1	1	R/W	1: Disables a key-sensing input interrupt
0	KMIMR0	1	R/W	request

Figure 5.2 shows the relationship between interrupts IRQ7 and IRQ6, interrupts KIN15 to KIN0, and KMIMR A and KMIMR.

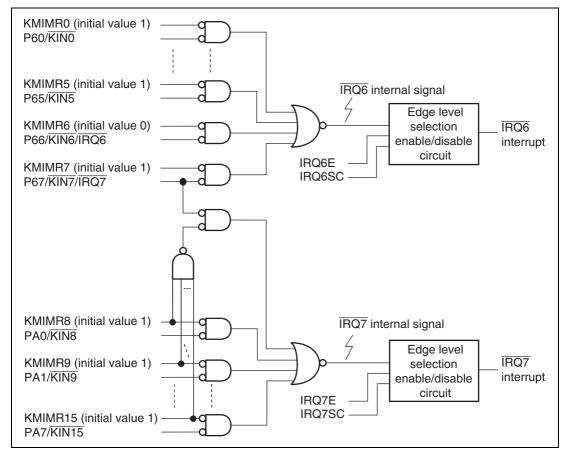

Figure 5.2 Relationship between Interrupts IRQ7 and IRQ6, Interrupts KIN15 to KIN0, and Registers KMIMR and KMIMRA

If any of bits KMIMR15 to KMIMR8 is cleared to 0, an interrupt input from the  $\overline{IRQ7}$  pin will be ignored. When pins  $\overline{KIN7}$  to  $\overline{KIN0}$  or  $\overline{KIN15}$  to  $\overline{KIN8}$  are used as key-sense interrupt input pins, either low-level sensing or falling-edge sensing must be specified as the interrupt sensing condition for the corresponding interrupt source (IRQ6 or IRQ7).

## 5.4 Interrupt Sources

#### 5.4.1 External Interrupts

There are three types of external interrupts: NMI, IRQ7 to IRQ0 and KIN15 to KIN0. KIN15 to KIN8 share the IRQ7 interrupt source, and KIN7 to KIN0 share the IRQ6 interrupt source. Of these, NMI, IRQ7, IRQ6, and IRQ2 to IRQ0 can be used to restore this LSI from software standby mode.

**NMI Interrupt:** NMI is the highest-priority interrupt, and is always accepted by the CPU regardless of the interrupt control mode or the status of the CPU interrupt mask bits. The NMIEG bit in SYSCR can be used to select whether an interrupt is requested at a rising edge or a falling edge on the NMI pin.

**IRQ7 to IRQ0 Interrupts:** Interrupts IRQ7 to IRQ0 are requested by an input signal at pins  $\overline{\text{IRQ7}}$  to  $\overline{\text{IRQ0}}$ . Interrupts IRQ7 to IRQ0 have the following features:

- The interrupt exception handling for interrupt requests IRQ7 to IRQ0 can be started at an independent vector address.
- Using ISCR, it is possible to select whether an interrupt is generated by a low level, falling edge, rising edge, or both edges, at pins IRQ7 to IRQ0.
- Enabling or disabling of interrupt requests IRQ7 to IRQ0 can be selected with IER.
- Interrupt control levels can be specified by the ICR settings.
- The status of interrupt requests IRQ7 to IRQ0 is indicated in ISR. ISR flags can be cleared to 0 by software.

The detection of IRQ7 to IRQ0 interrupts does not depend on whether the relevant pin has been set for input or output. However, when a pin is used as an external interrupt input pin, do not clear the corresponding DDR to 0 to use the pin as an I/O pin for another function.

A block diagram of interrupts IRQ7 to IRQ0 is shown in figure 5.3.

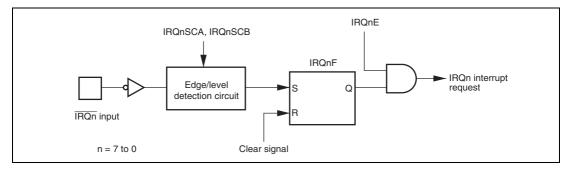

Figure 5.3 Block Diagram of Interrupts IRQ7 to IRQ0

When pin  $\overline{IRQ6}$  is used as an IRQ6 interrupt input pin, clear the KMIMR6 bit to 0.

When pin  $\overline{IRQ7}$  is used as an IRQ7 interrupt pin, set all of bits KMIMR15 to KMIMR8 to 1. If any of these bits is cleared to 0, IRQ7 interrupt input from the  $\overline{IRQ7}$  pin will be ignored.

Since interrupt request flags IRQ7F to IRQ0F are set each time the setting condition is satisfied, regardless of the IER setting, refer to a needed flag only.

 $\overline{\text{KIN15}}$  to  $\overline{\text{KIN0}}$  Interrupts: Interrupts KIN15 to KIN0 are requested by input signals on pins  $\overline{\text{KIN15}}$  to  $\overline{\text{KIN0}}$ . When pins  $\overline{\text{KIN15}}$  to  $\overline{\text{KIN0}}$  are used as key-sense inputs, clear a corresponding bit in KMIMR to 0 in order to enable their key-sense input interrupts. Remaining unused bits in KMIMR should be set to 1 in order to disable interrupts. Interrupts KIN15 to KIN8 are requested as an IRQ7 interrupt, and interrupts KIN7 to KIN0 are requested as an IRQ6 interrupt. The pin function, conditions of enabling or disabling interrupts, interrupt sense condition, and interrupt indicating method to generate a key-sense input interrupt depend on those for the IRQ7 or IRQ6 interrupt.

When pins  $\overline{\text{KIN7}}$  to  $\overline{\text{KIN0}}$ , or  $\overline{\text{KIN15}}$  to  $\overline{\text{KIN8}}$  are used as key-sense interrupt input pins, either low-level sensing or falling-edge sensing must be specified as the interrupt sense condition for the corresponding interrupt source (IRQ6 or IRQ7).

#### 5.4.2 Internal Interrupts

Internal interrupts issued from the on-chip peripheral modules have the following features:

- 1. For each on-chip peripheral module there are flags that indicate the interrupt request status, and enable bits that individually select enabling or disabling of these interrupts. When the enable bit for a particular interrupt source is set to 1, an interrupt request is sent to the interrupt controller.
- 2. The priority level for each interrupt can be set by ICR.

# 5.5 Interrupt Exception Handling Vector Table

Table 5.3 lists interrupt exception handling sources, vector addresses, and interrupt priorities. For default priorities, the lower the vector number, the higher the priority. Modules set at the same priority will conform to their default priorities. Priorities within a module are fixed.

An interrupt control level can be specified for a module to which an ICR bit is assigned. Interrupt requests from modules that are set to control level 1 (priority) by the ICR bit setting and the I and UI bits in CCR are given priority and processed before interrupt requests from modules that are set to control level 0 (no priority).

Table 5.3 Interrupt Sources, Vector Addresses, and Interrupt Priorities

Origin of			Vect	or Address

## 5.6 Interrupt Control Modes and Interrupt Operation

The interrupt controller has two modes: Interrupt control mode 0 and interrupt control mode 1. Interrupt operations differ depending on the interrupt control mode. NMI interrupts and address break interrupts are always accepted except for in reset state or in hardware standby mode. The interrupt control mode is selected by SYSCR. Table 5.4 shows the interrupt control modes.

**Table 5.4** Interrupt Control Modes

Interrupt Control	SY	'SCR	Priority – Setting	Interrupt		
Mode	INTM1			Mask Bits	Description	
0	0	0	ICR	I	Interrupt mask control is performed by the I bit. Priority levels can be set with ICR.	
1	_	1	ICR	I, UI	3-level interrupt mask control is performed by the I bit. Priority levels can be set with ICR.	

#### 5.6.1 Interrupt Control Mode 0

In interrupt control mode 0, interrupt requests other than NMI and address breaks are masked by ICR and the I bit of the CCR in the CPU. Figure 5.4 shows a flowchart of the interrupt acceptance operation.

- 1. If an interrupt source occurs when the corresponding interrupt enable bit is set to 1, an interrupt request is sent to the interrupt controller.
- 2. According to the interrupt control level specified in ICR, the interrupt controller only accepts an interrupt request with interrupt control level 1 (priority), and holds pending an interrupt request with interrupt control level 0 (no priority). If several interrupt requests are issued, an interrupt request with the highest priority is accepted according to the priority order, an interrupt handling is requested to the CPU, and other interrupt requests are held pending.
- 3. If the I bit in CCR is set to 1, only NMI and address break interrupts are accepted by the interrupt controller, and other interrupt requests are held pending. If the I bit is cleared to 0, any interrupt request is accepted.
- 4. When the CPU accepts an interrupt request, it starts interrupt exception handling after execution of the current instruction has been completed.
- 5. The PC and CCR are saved to the stack area by interrupt exception handling. The PC saved on the stack shows the address of the first instruction to be executed after returning from the interrupt handling routine.

- 6. Next, the I bit in CCR is set to 1. This masks all interrupts except for NMI and address break interrupts.
- 7. The CPU generates a vector address for the accepted interrupt and starts execution of the interrupt handling routine at the address indicated by the contents of the vector address in the vector table.

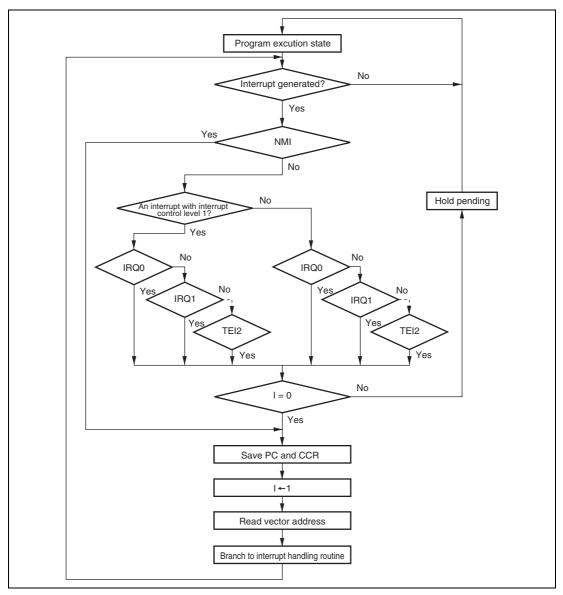

Figure 5.4 Flowchart of Procedure up to Interrupt Acceptance in Interrupt Control Mode 0

### 5.6.2 Interrupt Control Mode 1

In interrupt control mode 1, mask control is applied to three levels for IRQ and on-chip peripheral module interrupt requests by comparing the I and UI bits in CCR in the CPU, and the ICR setting.

- An interrupt request with interrupt control level 0 is accepted when the I bit in CCR is cleared to 0. When the I bit is set to 1, the interrupt request is held pending
- An interrupt request with interrupt control level 1 is accepted when the I bit or UI bit in CCR is cleared to 0. When both I and UI bits are set to 1, the interrupt request is held pending.

For instance, the state transition when the interrupt enable bit corresponding to each interrupt is set to 1, and ICRA to ICRC are set to H'20, H'00, and H'00, respectively (IRQ2 and IRQ3 interrupts are set to control level 1, and other interrupts are set to control level 0) is shown below. Figure 5.5 shows a state transition diagram.

- All interrupt requests are accepted when I = 0. (Priority order: NMI > IRQ2 > IRQ3 > address break > IRQ0 > IRQ1 ...)
- Only NMI, IRQ2, IRQ3 and address break interrupt requests are accepted when I = 1 and UI = 0.
- Only an NMI and address break interrupt request is accepted when I = 1 and UI = 1.

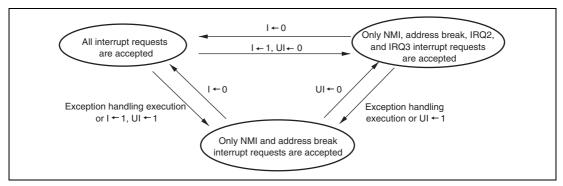

Figure 5.5 State Transition in Interrupt Control Mode 1

Figure 5.6 shows a flowchart of the interrupt acceptance operation.

- 1. If an interrupt source occurs when the corresponding interrupt enable bit is set to 1, an interrupt request is sent to the interrupt controller.
- 2. According to the interrupt control level specified in ICR, the interrupt controller only accepts an interrupt request with interrupt control level 1 (priority), and holds pending an interrupt request with interrupt control level 0 (no priority). If several interrupt requests are issued, an

- interrupt request with the highest priority is accepted according to the priority order, an interrupt handling is requested to the CPU, and other interrupt requests are held pending.
- 3. An interrupt request with interrupt control level 1 is accepted when the I bit is cleared to 0, or when the I bit is set to 1 while the UI bit is cleared to 0.
  - An interrupt request with interrupt control level 0 is accepted when the I bit is cleared to 0. When the I bit is set to 1, only an NMI or address break interrupt request is accepted, and other interrupts are held pending.
  - When both the I and UI bits are set to 1, only an NMI or address break interrupt request is accepted, and other interrupts are held pending.
  - When the I bit is cleared to 0, the UI bit is not affected.
- 4. When the CPU accepts an interrupt request, it starts interrupt exception handling after execution of the current instruction has been completed.
- 5. The PC and CCR are saved to the stack area by interrupt exception handling. The PC saved on the stack shows the address of the first instruction to be executed after returning from the interrupt handling routine.
- 6. The I and UI bits in CCR are set to 1. This masks all interrupts except for an NMI or address break interrupt.
- The CPU generates a vector address for the accepted interrupt and starts execution of the interrupt handling routine at the address indicated by the contents of the vector address in the vector table.

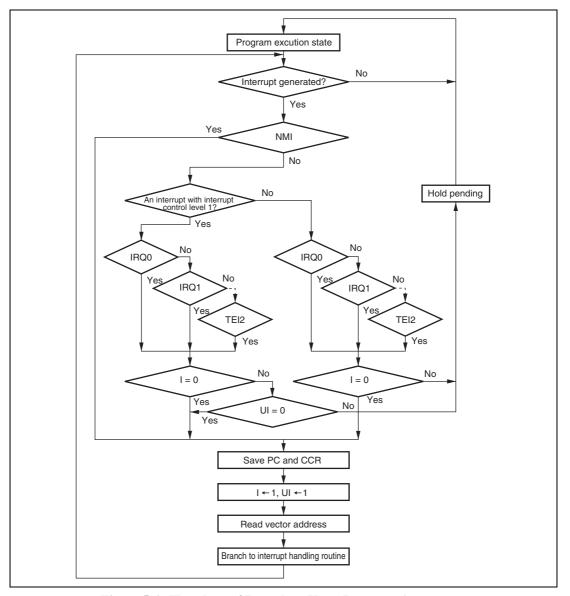

Figure 5.6 Flowchart of Procedure Up to Interrupt Acceptance in Interrupt Control Mode 1

# **5.6.3** Interrupt Exception Handling Sequence

Figure 5.7 shows the interrupt exception handling sequence. The example shown is for the case where interrupt control mode 0 is set in advanced mode, and the program area and stack area are in on-chip memory.

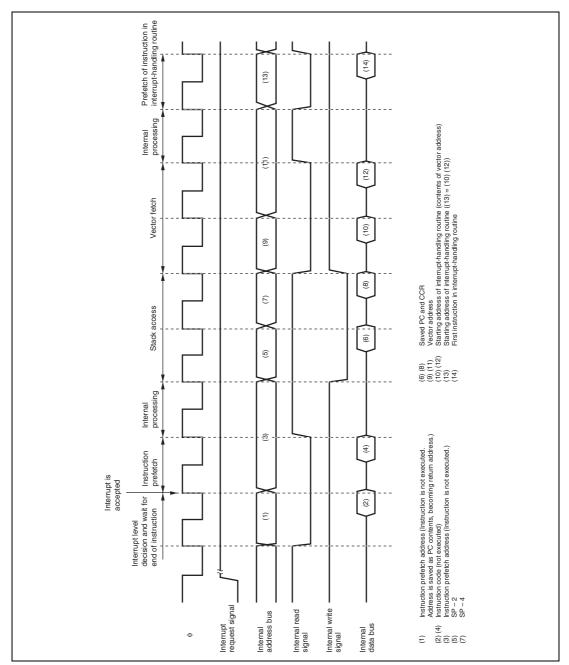

Figure 5.7 Interrupt Exception Handling

### 5.6.4 Interrupt Response Times

Table 5.5 shows interrupt response times – the intervals between generation of an interrupt request and execution of the first instruction in the interrupt handling routine. The execution status symbols used in table 5.5 are explained in table 5.6.

**Table 5.5** Interrupt Response Times

No.	Execution Status	Normal Mode	Advanced Mode			
1	Interrupt priority determination* <sup>1</sup>	3				
2	Number of wait states until executing instruction ends*2	1 to (19 + 2·Sı)				
3	PC, CCR stack save	2·Sĸ	2·Sĸ			
4	Vector fetch	Sı	2⋅Sı			
5	Instruction fetch*3	2∙Sı				
6	Internal processing*4		2			
	Total (using on-chip memory)	11 to 31	12 to 32			

Notes: 1. Two states in case of internal interrupt.

- 2. Refers to MULXS and DIVXS instructions.
- 3. Prefetch after interrupt acceptance and prefetch of interrupt handling routine.
- 4. Internal processing after interrupt acceptance and internal processing after vector fetch.

Table 5.6 Number of States in Interrupt Handling Routine Execution Status

	Object of Access						
			Exteri	nal Device			
		8-B	it Bus	16-Bit Bus

Instruction fetch Sı	1	4	6 + 2m	2	3 + m		
Branch address read SJ							
Stack manipulation Sk							
rı 13							

[Legend]

m: Number of wait states in external device access

#### 5.7 Address Break

#### 5.7.1 Features

This LSI can determine the specific address prefetch by the CPU to generate an address break interrupt by setting ABRKCR and BAR. If an address break interrupt is generated, the address break interrupt exception handling is performed.

With this function, the execution start point of a program containing a bug is detected and execution is branched to the correcting program.

#### 5.7.2 Block Diagram

Figure 5.8 shows a block diagram of the address break.

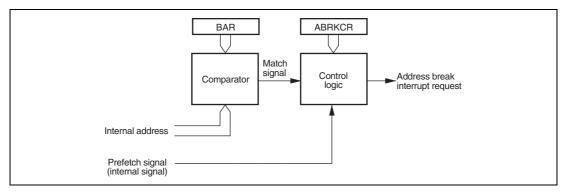

Figure 5.8 Address Break Block Diagram

## 5.7.3 Operation

If the CPU prefetches an address specified in BAR by setting ABRKCR and BAR, an address break interrupt can be generated. This address break function generates an interrupt request to the interrupt controller at prefetch, and determines the priority by the interrupt controller. When an interrupt is accepted, an interrupt exception handling is activated after the current instruction has been completed. Note that the interrupt mask control according to the I and UI bits in CCR of the CPU is invalid to an address break interrupt.

To use the address break function, set each register as follows:

1. Set a break address in the A23 to A1 bits in BAR.

2. Set the BIE bit in ABRKCR to 1 to enable the address break.

When the BIE bit is cleared to 0, an address break is not requested.

When the setting conditions are satisfied, the CMF flag in ABRKCR is set to 1 to request an interrupt. The interrupt source should be determined by the interrupt handling routine if necessary.

#### 5.7.4 Usage Notes

- 1. In an address break, the break address should be an address where the first byte of the instruction exists. Otherwise, a break condition will not be satisfied.
- 2. In normal mode, addresses A23 to A16 are not compared.
- 3. When the branch instructions (Bcc, BSR), jump instructions (JMP, JSR), RST instruction, and RTE instruction are placed immediately prior to the address specified by BAR, a prefetch signal to the address may be output to request an address break by executing these instruction. It is necessary to take countermeasures: do not set a break address to an address immediately after these instructions, or determine whether interrupt handling is performed by satisfaction of a normal condition.
- 4. An address break interrupt is generated by combining the internal prefetch signal and an address. Therefore, the timing to enter the interrupt exception handling differs according to the instructions at the specified and at prior addresses and execution cycles.

Figure 5.9 shows an example of address timing.

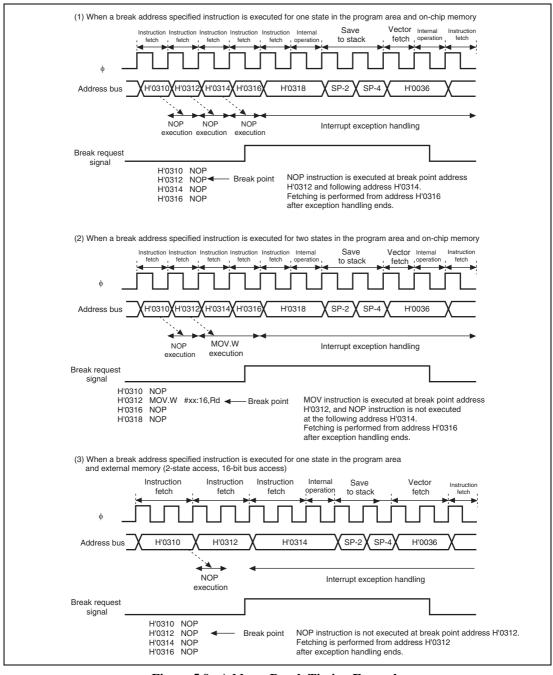

Figure 5.9 Address Break Timing Example

## 5.8 Usage Notes

#### 5.8.1 Conflict between Interrupt Generation and Disabling

When an interrupt enable bit is cleared to 0 to disable interrupt requests, the disabling becomes effective after execution of the instruction. When an interrupt enable bit is cleared to 0 by an instruction such as BCLR or MOV, and if an interrupt is generated during execution of the instruction, the interrupt concerned will still be enabled on completion of the instruction, so interrupt exception handling for that interrupt will be executed on completion of the instruction. However, if there is an interrupt request of higher priority than that interrupt, interrupt exception handling will be executed for the higher-priority interrupt, and the lower-priority interrupt will be ignored. The same rule is also applied when an interrupt source flag is cleared to 0. Figure 5.10 shows an example in which the CMIEA bit in the TMR's TCR register is cleared to 0.

The above conflict will not occur if an enable bit or interrupt source flag is cleared to 0 while the interrupt is masked.

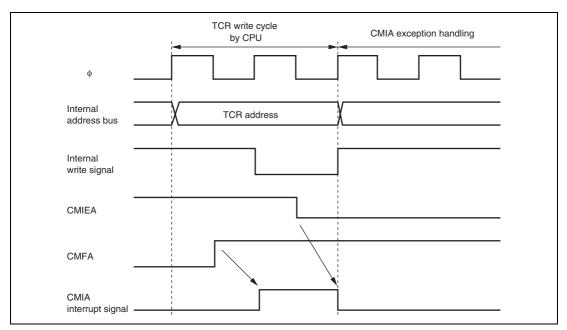

Figure 5.10 Conflict between Interrupt Generation and Disabling

#### **5.8.2** Instructions that Disable Interrupts

The instructions that disable interrupts are LDC, ANDC, ORC, and XORC. After any of these instructions are executed, all interrupts including NMI are disabled and the next instruction is always executed. When the I bit or UI bit is set by one of these instructions, the new value becomes valid two states after execution of the instruction ends.

### 5.8.3 Interrupts during Execution of EEPMOV Instruction

Interrupt operation differs between the EEPMOV.B instruction and the EEPMOV.W instruction.

With the EEPMOV.B instruction, an interrupt request (including NMI) issued during the transfer is not accepted until the move is completed.

With the EEPMOV.W instruction, if an interrupt request is issued during the transfer, interrupt exception handling starts at a break in the transfer cycle. The PC value saved on the stack in this case is the address of the next instruction. Therefore, if an interrupt is generated during execution of an EEPMOV.W instruction, the following coding should be used.

L1: EEPMOV.W

MOV.W R4,R4

## 5.8.4 IRQ Status Register (ISR)

According to the pin status after a reset, IRQnF may be set to 1, so ISR should be read after a reset to write 0. (n = 7 to 0)

# Section 6 Bus Controller (BSC)

This LSI has an on-chip bus controller (BSC) that can specify the bus settings such as the bus width and the number of access cycles of the external address space.

#### 6.1 Features

- Basic bus interface
  - 2-state access or 3-state access can be selected for each area
  - Program wait cycles can be inserted for each area
- Burst ROM interface
  - A burst ROM interface can be set for basic expansion areas
  - 1-state access or 2-state access can be selected for burst access
- Idle cycle insertion

An idle cycle can be inserted for external write cycles immediately after external read cycles

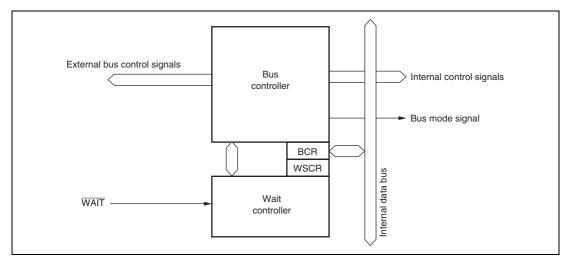

Figure 6.1 Block Diagram of Bus Controller

# 6.2 Input/Output Pins

Tables 6.1 and 6.2 summarize the pin configuration of the bus controller.

Table 6.1 Pin Configuration of H8S/2144B

Symbol	I/O	Function
ĀS	Output	Strobe signal indicating that address output on the address bus is valid (when the IOSE bit in SYSCR is cleared to 0).
ĪOS	Output	I/O select signal (when the IOSE bit in SYSCR is set to 1).
RD	Output	Strobe signal indicating that the external address space is being read.
HWR	Output	Strobe signal indicating that the external address space is being written to, and the upper byte (D15 to D8) of the data bus is valid.
LWR	Output	Strobe signal indicating that the external address space is being written to, and the lower byte (D7 to D0) of the data bus is valid.
WAIT	Input	Wait request signal when accessing the external 3-state access space.

Table 6.2 Pin Configuration of H8S/2134B

Symbol	I/O	Function
ĀS	Output	Strobe signal indicating that address output on the address bus is valid (when the IOSE bit in SYSCR is cleared to 0).
ĪOS	Output	I/O select signal (when the IOSE bit in SYSCR is set to 1).
RD	Output	Strobe signal indicating that the external address space is being read.
WR	Output	Strobe signal indicating that the external address space is being written to, and the data bus (D7 to D0) is valid.
WAIT	Input	Wait request signal when accessing the external 3-state access space.

# 6.3 Register Descriptions

The bus controller has the following registers. For details on the system control register, refer to section 3.2.2, System Control Register (SYSCR).

- Bus control register (BCR)
- Wait state control register (WSCR)

## 6.3.1 Bus Control Register (BCR)

BCR is used to specify the access mode for the external address space or the I/O area range when the  $\overline{AS/IOS}$  pin is specified as an I/O strobe pin.

Bit	Bit Name	Initial Value	R/W	Description
7	_	1	R/W	Reserved
				This bit should not be written by 0.
6	ICIS0	1	R/W	Idle Cycle Insertion
				Selects whether or not to insert 1-state of the idle cycle between bus cycles when the external write cycle follows the external read cycle.
				0: Idle cycle not inserted when the external write cycle follows the external read cycle
				1: 1-state idle cycle inserted when the external write cycle follows the external read cycle
5	BRSTRM	0	R/W	Burst ROM Enable
				Selects the bus interface for the external address space.
				0: Basic bus interface
				1: Burst ROM interface
4	BRSTS1	1	R/W	Burst Cycle Select 1
				Selects the number of cycles in the burst cycle of the burst ROM interface.
				0: 1 cycle
				1: 2 cycles

Bit	Bit Name	Initial Value	R/W	Description
3	BRSTS0	0	R/W	Burst Cycle Select 0
				Selects the number of words that can be accessed by burst access via the burst ROM interface.
				0: Max, 4 words
				1: Max, 8 words
2	_	0	R/W	Reserved
				This bit should not be written by 0.
1	IOS1	1	R/W	IOS Select 1, 0
0	IOS0	1	R/W	Select the address range where the $\overline{\text{IOS}}$ signal is output. For details, refer to table 6.4, Address Range for IOS Signal Output.

### 6.3.2 Wait State Control Register (WSCR)

WSCR is used to specify the data bus width for external address space access, the number of access cycles, the wait mode, and the number of wait cycles for access to external address spaces. The bus width and the number of access cycles for internal memory and internal I/O registers are fixed regardless of the WSCR settings.

Bit	Bit Name	Initial Value	R/W	Description
7	_	0	R/W	Reserved
6	_	0	R/W	These bits should not be written by 1.
5	ABW	1	R/W	Bus Width Control
				Selects 8 or 16bits for access to the external address space.
				0: 16-bit access space*
				1: 8-bit access space

Bit	Bit Name	Initial Value	R/W	Description
4	AST	1	R/W	Access State Control
				Selects 2 or 3 access cycles for access to the external address space. This bit also enables or disables wait-cycle insertion.
				0: 2-state access space. Wait cycle insertion disabled in external address space access
				1: 3-state access space. Wait cycle insertion enabled in external address space access
3	WMS1	0	R/W	Wait Mode Select 1, 0
2	WMS0	0	R/W	Select the wait mode for access to the external address space when the AST bit is set to 1.
				00: Program wait mode
				01: Wait disabled mode
				10: Pin wait mode
				11: Pin auto-wait mode
1	WC1	1	R/W	Wait Count 1, 0
0	WC0	1	R/W	Select the number of program wait cycles to be inserted when the external address space is accessed while the AST bit is set to 1.
				00: Program wait cycle is not inserted
				01: 1 program wait cycle is inserted
				10: 2 program wait cycles are inserted
				11: 3 program wait cycles are inserted

Note: \* Setting prohibited in the H8S/2134B.

#### 6.4 Bus Control

#### 6.4.1 Bus Specifications

The external address space bus specifications consist of three elements: Bus width, the number of access cycles, and the wait mode and the number of program wait cycles. The bus width and the number of access cycles for on-chip memory and internal I/O registers are fixed, and are not affected by the bus controller settings.

**Bus Width:** A bus width of 8 or 16 bits can be selected by the ABW bit in WSCR. Note that the 16-bit bus width cannot be set in the H8S/2134B.

**Number of Access Cycles:** Two or three access cycles can be selected via the AST bit in WSCR. When the 2-state access space is designated, wait-cycle insertion is disabled.

In the burst ROM interface, the number of access cycles is determined regardless of the AST bit setting.

**Wait Mode and Number of Program Wait Cycles:** When a 3-state access space is designated by the AST bit in WSCR, the wait mode and the number of program wait cycles to be inserted automatically is selected by the WMS1, WMS0, WC1, and WC0 bits in WSCR. From 0 to 3 program wait cycles can be selected.

Dua Cassifications

Table 6.3 shows the bus specifications for the basic bus interface of each area.

Table 6.3 Bus Specifications for Basic Bus Interface

						Bus Specifications		
ABW	AST	WMS1	WMS	WC1	WC0	Bus Width	Number of Access Cycles	Number of Program Wait Cycles
0	0	_	_	_	_	16	2	0
	1	0	1	_	_	16	3	0
		*	*	0	0		3	0
					1	_		1
				1	0	<del>_</del>		2
					1	<del>_</del>		3
1	0	_	_	_	_	8	2	0
	1	0	1	_	_	8	3	0
		*	*	0	0	_	3	0
					1	<del>_</del>		1
				1	0	_		2
					1	_		3

Note: \* Other than WMS1 = 0 and WMS0 = 1

#### 6.4.2 Advanced Mode

The external address space is initialized to the basic bus interface and a 3-state access space. In onchip ROM enabled extended mode, the address space other than on-chip ROM, on-chip RAM, internal I/O registers, and their reserved areas is specified as the external address space. The onchip RAM and its reserved area are enabled when the RAME bit in SYSCR is set to 1. They are disabled and corresponding addresses are the external address space when the RAME bit is cleared to 0.

In the H8S/2134B, the upper address in advanced mode (A16 to A23) cannot be output since there are only 16 address output pins. However, an area from H'FFF000 to H'FFF7FF can be accessed using the  $\overline{\text{AS/IOS}}$  signal specified as the I/O select signal. Therefore, the area can be accessed even when the H8S/2134B operates in ROM disabled extended and advanced mode.

#### 6.4.3 Normal Mode

The external address space is initialized as the basic bus interface and a 3-state access space. In on-chip ROM disable extended mode, the address space other than on-chip RAM and internal I/O registers is specified as the external address space. In on-chip ROM enable extended mode, the address space other than on-chip ROM, on-chip RAM, internal I/O registers, and their reserved areas is specified as the external address space. The on-chip RAM area is enabled when the RAME bit in SYSCR is set to 1, and disabled and specified as the external address space when the RAME bit is cleared to 0.

### 6.4.4 I/O Select Signals

The LSI can output I/O select signals ( $\overline{\text{IOS}}$ ); the signal is driven low when the corresponding external address space is accessed. Figure 6.2 shows an example of  $\overline{\text{IOS}}$  signal output timing.

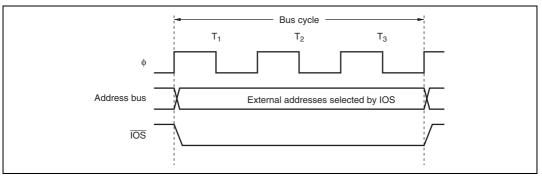

Figure 6.2 TOS Signal Output Timing

Enabling or disabling  $\overline{IOS}$  signal output is performed by the IOSE bit in SYSCR. In extended mode, the  $\overline{IOS}$  pin functions as an  $\overline{AS}$  pin by a reset. To use this pin as an  $\overline{IOS}$  pin, set the IOSE bit to 1. For details, refer to section 7, I/O Ports.

The address ranges of the  $\overline{\text{IOS}}$  signal output can be specified by the IOS1 and IOS0 bits in BCR, as shown in table 6.4.

Table 6.4	Address R	nge for <del>IOS</del> Signal Output				
IOS1	IOS0	IOS Signal Output Range				
0 0		H'(FF)F000 to H'(FF)F03F				
	1	H'(FF)F000 to H'(FF)F0FF				
1	0	H'(FF)F000 to H'(FF)F3FF				
	1	H'(FF)F000 to H'(FF)F7FF	(Initial value)			

#### 6.5 Basic Bus Interface

The basic bus interface enables direct connection to ROM and SRAM. For details on selection of the bus specifications when using the basic bus interface, see table 6.3

### 6.5.1 Data Size and Data Alignment

Data sizes for the CPU and other internal bus masters are byte, word, and longword. The BSC has a data alignment function, and controls whether the upper data bus (D15 to D8) or lower data bus (D7 to D0) is used when the external address space is accessed, according to the bus specifications for the area being accessed (8-bit access space or 16-bit access space) and the data size.

**8-Bit Access Space:** Figure 6.3 illustrates data alignment control for the 8-bit access space. With the 8-bit access space, the upper data bus (D15 to D8) is always used for accesses. The amount of data that can be accessed at one time is one byte: a word access is performed as two byte accesses, and a longword access, as four byte accesses.

In the H8S/2134B, eight bits of the data bus are available (D7 to D0) and only the 8-bit access space is settable. Therefore, data alignment described in this section is not performed.

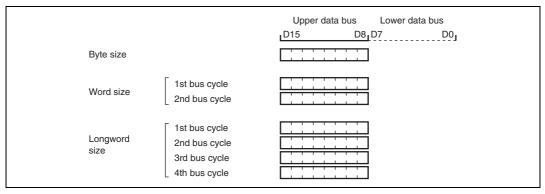

Figure 6.3 Access Sizes and Data Alignment Control (8-Bit Access Space)

**16-Bit Access Space (Not available for the H8S/2134B):** Figure 6.4 illustrates data alignment control for the 16-bit access space. With the 16-bit access space, the upper data bus (D15 to D8) and lower data bus (D7 to D0) are used for accesses. The amount of data that can be accessed at one time is one byte or one word, and a longword access is executed as two word accesses.

In byte access, whether the upper or lower data bus is used is determined by whether the address is even or odd. The upper data bus is used for an even address, and the lower data bus for an odd address.

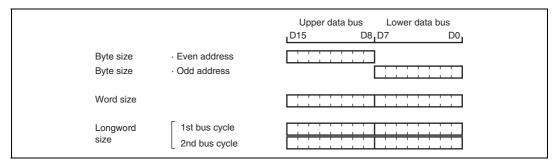

Figure 6.4 Access Sizes and Data Alignment Control (16-bit Access Space)

#### 6.5.2 Valid Strobes

Table 6.5 shows the data buses used and valid strobes for each access space.

In a read, the  $\overline{RD}$  signal is valid for both the upper and lower bytes of the data bus. In a write, the  $\overline{HWR}$  signal is valid for the upper byte of the data bus, and the  $\overline{LWR}$  signal for the lower byte.

In the H8S/2134B, only eight bits of the data bus is valid (D7 to D0). The strobe signals corresponding to the 8-bit data bus are the  $\overline{RD}$  and  $\overline{WR}$  signal. The  $\overline{WR}$  signal in the H8S/2134B is the equivalent of the  $\overline{HWR}$  signal in the H8S/2144B.

Table 6.5 Data Buses Used and Valid Strobes

					H8S/2144B		H8S/2134B
Area	Access Size	Read/ Write	Address	Valid Strobe	Upper Data Bus (D15 to D8)	Lower Data Bus (D7 to D0)	Data Bus (D7 to D0)
8-bit access space	Byte	Read	_	RD	Valid	Ports or others	Valid
		Write	_	HWR (WR)	_	Ports or others	_
16-bit access	Byte	Read	Even	RD	Valid	Invalid	Valid
space [H8S/2144B]			Odd	=	Invalid	Valid	Invalid
[1100/21448]		Write	Even	HWR	Valid	Undefined	Valid
			Odd	LWR	Undefined	Valid	Undefined
	Word	Read	_	RD	Valid	Valid	Valid
		Write	_	HWR, LWR	Valid	Valid	Valid

Note: \* Undefined: Undefined data is output.

Invalid: Input state with the input value ignored.

Ports or others: Used as ports or I/O pins for on-chip peripheral modules, and are not used as the data bus.

## 6.5.3 Basic Operation Timing

**8-Bit, 2-State Access Space:** Figure 6.5 shows the bus timing for an 8-bit, 2-state access space. When an 8-bit access space is accessed, the upper byte (D15 to D8) of the data bus is used in the H8S/2144B. Wait cycles cannot be inserted.

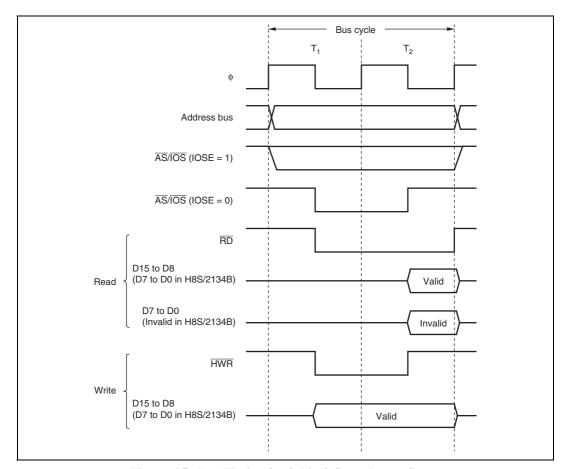

Figure 6.5 Bus Timing for 8-Bit, 2-State Access Space

**8-Bit, 3-State Access Space:** Figure 6.6 shows the bus timing for an 8-bit, 3-state access space. When an 8-bit access space is accessed, the upper byte (D15 to D8) of the data bus is used in the H8S/2144B. Wait cycles can be inserted.

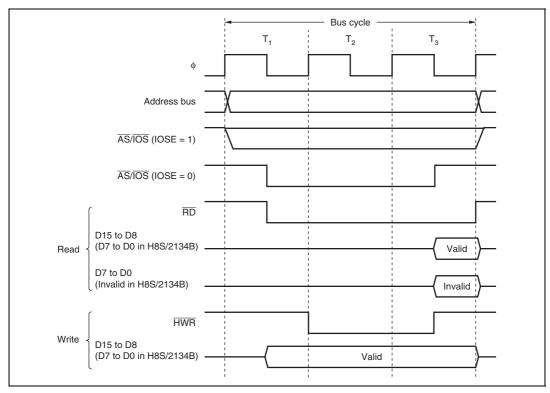

Figure 6.6 Bus Timing for 8-Bit, 3-State Access Space

**16-Bit, 2-State Access Space [Available for H8S/2144B]:** Figures 6.7 to 6.9 show bus timings for a 16-bit, 2-state access space. When a 16-bit access space is accessed, the upper byte (D15 to D8) of the data bus is used for even addresses, and the lower byte (D7 to D0) for odd addresses. Wait cycles cannot be inserted.

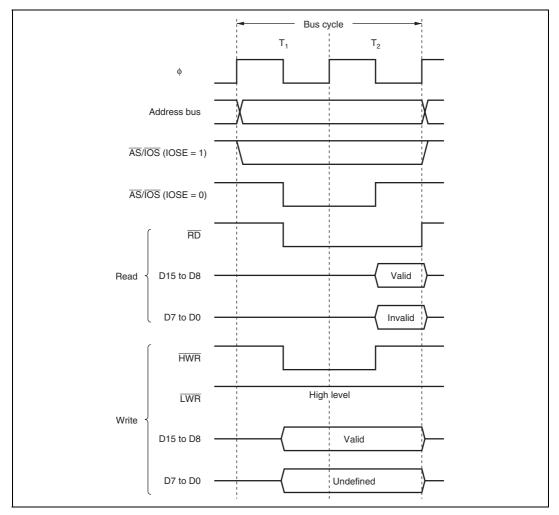

Figure 6.7 Bus Timing for 16-Bit, 2-State Access Space (Even Byte Access)

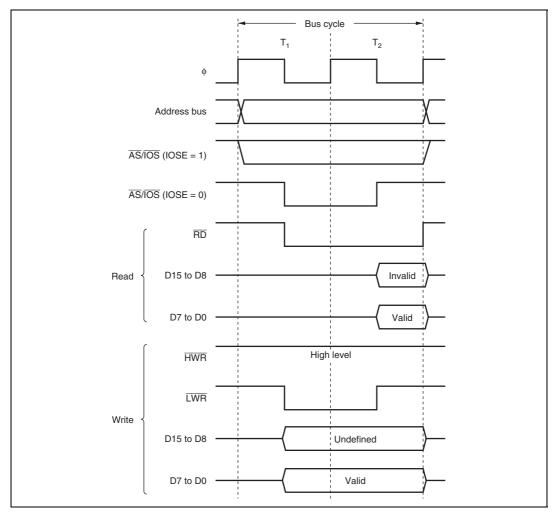

Figure 6.8 Bus Timing for 16-Bit, 2-State Access Space (Odd Byte Access)

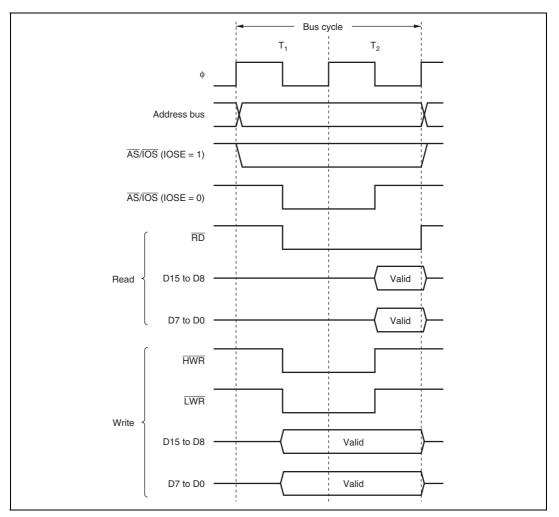

Figure 6.9 Bus Timing for 16-Bit, 2-State Access Space (Word Access)

**16-Bit, 3-State Access Space [Available for H8S/2144B]:** Figures 6.10 to 6.12 show bus timings for a 16-bit, 3-state access space. When a 16-bit access space is accessed, the upper byte (D15 to D8) of the data bus is used for even addresses, and the lower byte (D7 to D0) for odd addresses. Wait cycles can be inserted.

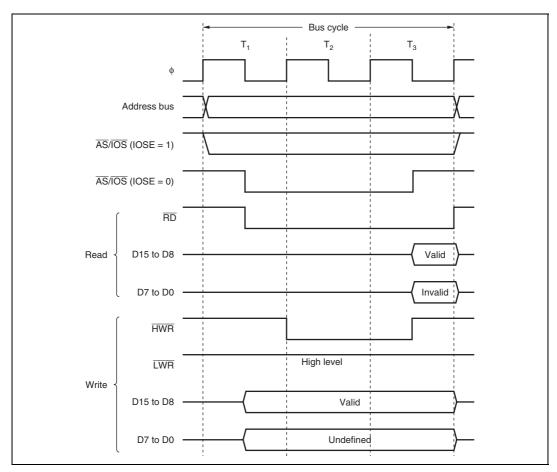

Figure 6.10 Bus Timing for 16-Bit, 3-State Access Space (Even Byte Access)

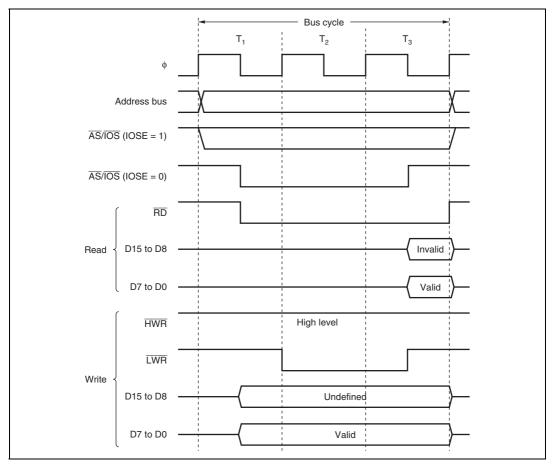

Figure 6.11 Bus Timing for 16-Bit, 3-State Access Space (Odd Byte Access)

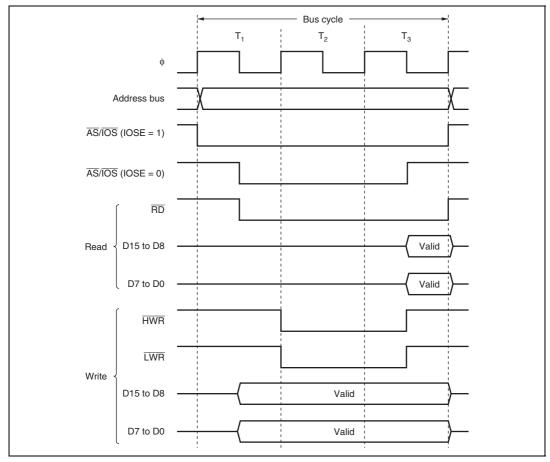

Figure 6.12 Bus Timing for 16-Bit, 3-State Access Space (Word Access)

### 6.5.4 Wait Control

When accessing the external address space, this LSI can extend the bus cycle by inserting one or more wait cycles ( $T_w$ ). There are three ways of inserting wait cycles: Program wait insertion, pin wait insertion using the  $\overline{WAIT}$  pin, and the combination of program wait and the  $\overline{WAIT}$  pin.

**Program Wait Mode:** A specified number of wait cycles  $T_w$  can be inserted automatically between the  $T_2$  state and  $T_3$  state when accessing the external address space always according to the settings of the WC1 and WC0 bits in WSCR.

**Pin Wait Mode:** A specified number of wait cycles  $T_w$  can be inserted automatically between the  $T_2$  state and  $T_3$  state when accessing the external address space always according to the settings of the WC1 and WC0 bits. If the  $\overline{WAIT}$  pin is low at the falling edge of  $\phi$  in the last  $T_2$  or  $T_w$  state, another  $T_w$  state is inserted. If the  $\overline{WAIT}$  pin is held low,  $T_w$  states are inserted until it goes high.

This is useful when inserting four or more  $T_w$  states, or when changing the number of  $T_w$  states to be inserted for each external device.

**Pin Auto-Wait Mode:** A specified number of wait cycles  $T_w$  can be inserted automatically between the  $T_2$  state and  $T_3$  state when accessing the external address space according to the settings of the WC1 and WC0 bits if the  $\overline{WAIT}$  pin is low at the falling edge of  $\phi$  in the last  $T_2$  state. Even if the  $\overline{WAIT}$  pin is held low,  $T_w$  states can be inserted only up to the specified number of cycles.

This function enables the low-speed memory interface only by inputting the chip select signal to the  $\overline{WAIT}$  pin.

Figure 6.13 shows an example of wait cycle insertion timing in pin wait mode.

The settings after a reset are: 3-state access, 3 program wait insertion, and  $\overline{WAIT}$  pin input disabled.

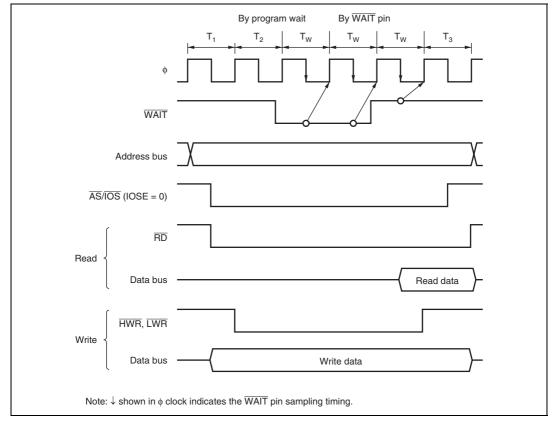

Figure 6.13 Example of Wait Cycle Insertion Timing (Pin Wait Mode)

### **6.6** Burst ROM Interface

In this LSI, the external address space can be designated as the burst ROM space by setting the BRSTRM bit in BCR to 1, and the burst ROM interface enabled. Consecutive burst accesses of a maximum four or eight words can be performed only during CPU instruction fetch. One or two cycles can be selected for burst ROM access.

### 6.6.1 Basic Operation Timing

The number of access cycles in the initial cycle (full access) of the burst ROM interface is determined by the AST bit in WSCR. When the AST bit is set to 1, wait cycles can be inserted. One or two cycles can be selected for burst access according to the setting of the BRSTS1 bit in BCR. Wait cycles cannot be inserted in a burst cycle. Burst accesses of a maximum four words is performed when the BRSTS0 bit in BCR is cleared to 0, and burst accesses of a maximum eight words is performed when the BRSTS0 bit in BCR is set to 1.

The basic access timing for the burst ROM space is shown in figures 6.14 and 6.15.

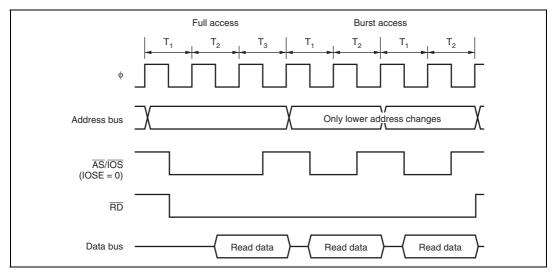

Figure 6.14 Access Timing Example in Burst ROM Space (AST = BRSTS1 = 1)

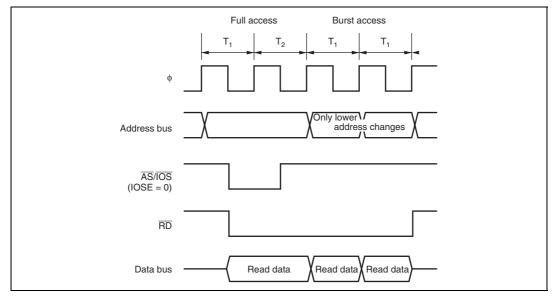

Figure 6.15 Access Timing Example in Burst ROM Space (AST = BRSTS1 = 0)

### 6.6.2 Wait Control

As with the basic bus interface, program wait insertion or pin wait insertion using the  $\overline{WAIT}$  pin can be used in the initial cycle (full access) of the burst ROM interface. For details, see section 6.5.4, Wait Control. Wait cycles cannot be inserted in a burst cycle.

## 6.7 Idle Cycle

When this LSI accesses the external address space, it can insert a 1-state idle cycle (T<sub>1</sub>) between bus cycles when a write cycle occurs immediately after a read cycle. By inserting an idle cycle it is possible, for example, to avoid data collisions between ROM with a long output floating time, and high-speed memory and I/O interfaces.

If an external write occurs after an external read while the ICISO bit is set to 1 in BCR, an idle cycle is inserted at the start of the write cycle.

Figure 6.16 shows examples of idle cycle operation. In these examples, bus cycle A is a read cycle for ROM with a long output floating time, and bus cycle B is a CPU write cycle. In figure 6.16 (a), with no idle cycle inserted, a collision occurs in bus cycle B between the read data from ROM and the CPU write data. In figure 6.16 (b), an idle cycle is inserted, thus preventing data collision.

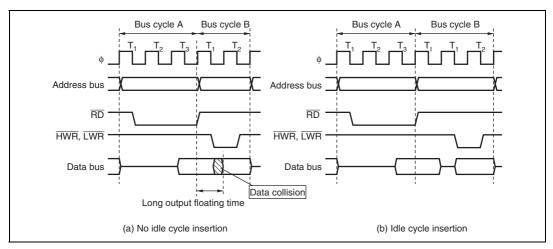

Figure 6.16 Examples of Idle Cycle Operation

Table 6.6 shows the pin states in an idle cycle.

**Table 6.6** Pin States in Idle Cycle

A23 to A0, <del>IOS</del>	A15 to A0, IOS	Contents of immediately following bus cycle
D15 to D0	D7 to D0	High impedance
ĀS	ĀS	High
RD	RD	High
HWR, LWR	WR	High

# Section 7 I/O Ports

### 7.1 Overview

In the H8S/2144B, ten I/O ports (ports 1 to 6, 8, 9, A, and B) and one input-only port (port 7) are included. In the H8S/2134B, eight I/O ports (ports 1 to 6, 8, and 9) and one input-only port (port 7) are included.

Table 7.1 is a summary of the port functions. The pins of each port also have other functions.

Each port includes a data direction register (DDR) that controls input/output (not provided for the input-only port) and data registers (DR, ODR) that store output data.

Ports 1 to 3, 6, A, and B have an on-chip input pull-up MOS function. For ports A and B, the on/off status of the input pull-up MOS is controlled by DDR and ODR. Ports 1 to 3 and 6 have an input pull-up MOS control register (PCR), in addition to DDR and DR, to control the on/off status of the input pull-up MOS.

Ports 1 to 6, 8, 9, A, and B can drive a single TTL load and 30 pF capacitive load. All the I/O ports can drive a Darlington transistor when in output mode. Ports 1, 2, and 3 can drive an LED (10 mA sink current).

Port A input and output use by the VccB power supply, which is independent of the  $V_{cc}$  power supply. When the VccB voltage is 5V, the pins on port A will be 5-V tolerant.

PA4 to PA7 of port A have the capability to drive bus buffers.

### 7.2 Port 1

Port 1 is an 8-bit I/O port. Port 1 pins also function as address output pins. Port 1 functions change according to the operating mode. Port 1 has an on-chip input pull-up MOS function that can be controlled by software. Port 1 has the following registers.

- Port 1 data direction register (P1DDR)
- Port 1 data register (P1DR)
- Port 1 pull-up MOS control register (P1PCR)

## 7.2.1 Port 1 Data Direction Register (P1DDR)

P1DDR specifies input or output for the pins of port 1 on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	P17DDR	0	W	In mode 1:
6	P16DDR	0	W	Each pin of port 1 is address output regardless of
5	P15DDR	0	W	the set value of P1DDR.
4	P14DDR	0	W	In modes 2 and 3 (EXPE=1):
3	P13DDR	0	W	The corresponding port 1 pins are address output ports when P1DDR bits are set to 1, and input ports
2	P12DDR	0	W	when cleared to 0.
1	P11DDR	0	W	In modes 2 and 3 (EXPE=0):
0	P10DDR	0	W	The corresponding port 1 pins are output ports when the P1DDR bits are set to 1, and input ports when cleared to 0.

# 7.2.2 Port 1 Data Register (P1DR)

P1DR stores output data for the port 1 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	P17DR	0	R/W	If a port 1 read is performed while the P1DDR bits
6	P16DR	0	R/W	are set to 1, the P1DR values are read. If a port 1 read is performed while the P1DDR bits are cleared
5	P15DR	0	R/W	to 0, the pin states are read.
4	P14DR	0	R/W	<del>-</del>
3	P13DR	0	R/W	<del>-</del>
2	P12DR	0	R/W	<del>-</del>
1	P11DR	0	R/W	_
0	P10DR	0	R/W	<del>-</del>

# 7.2.3 Port 1 Pull-Up MOS Control Register (P1PCR)

P1PCR controls the on/off status of the port 1 on-chip input pull-up MOSs.

Bit	Bit Name	Initial Value	R/W	Description
7	P17PCR	0	R/W	When the pins are in input state, the corresponding
6	P16PCR	0	R/W	input pull-up MOS is turned on when a P1PCR bit is set to 1.
5	P15PCR	0	R/W	_ 10 30t to 1.
4	P14PCR	0	R/W	_
3	P13PCR	0	R/W	_
2	P12PCR	0	R/W	_
1	P11PCR	0	R/W	_
0	P10PCR	0	R/W	_

#### 7.2.4 Pin Functions

P17/A7, P16/A6, P15/A5, P14/A4, P13/A3, P12/A2, P11/A1, and P10/A0
 Pin functions are switched as shown below according to the combination of the P1nDDR bit and operating mode.

Operating Mode	Mode 1	Mode 2, 3	(EXPE = 1)	Mode 2, 3 (EXPE = 0)		
P1nDDR	_	0	1	0	1	
Pin Function	A7 to A0 output pins	P17 to P10 input pins	A7 to A0 output pins	P17 to P10 input pins	P17 to P10 output pins	

[Legend]

n = 7 to 0

## 7.2.5 Port 1 Input Pull-Up MOS

Port 1 has an on-chip input pull-up MOS function that can be controlled by software. This input pull-up MOS function can be specified as on or off on a bit-by-bit basis.

Table 7.3 summarizes the input pull-up MOS states.

**Table 7.3** Input Pull-Up MOS States (Port 1)

Mode	Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1	Off	Off	Off	Off
2, 3			On/Off	On/Off

[Legend]

Off: Input pull-up MOS is always off.

On/Off: On when the pin is in the input state, P1DDR = 0, and P1PCR = 1; otherwise off.

## 7.3 Port 2

Port 2 is an 8-bit I/O port. Port 2 pins also function as address bus output pins. Port 2 functions change according to the operating mode. Port 2 has an on-chip input pull-up MOS function that can be controlled by software. Port 2 has the following registers.

- Port 2 data direction register (P2DDR)
- Port 2 data register (P2DR)
- Port 2 pull-up MOS control register (P2PCR)

## 7.3.1 Port 2 Data Direction Register (P2DDR)

P2DDR specifies input or output for the pins of port 2 on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	P27DDR	0	W	In Mode 1:
6	P26DDR	0	W	The corresponding port 2 pins are address outputs,
5	P25DDR	0	W	regardless of the P2DDR setting.
4	P24DDR	0	W	Modes 2 and 3 (EXPE = 1):
3	P23DDR	0	W	<ul> <li>The corresponding port 2 pins are address outputs</li> <li>when P2DDR bits are set to 1, and input ports</li> </ul>
2	P22DDR	0	W	when cleared to 0. P27 to P24 are switched from
1	P21DDR	0	W	<ul> <li>address outputs to output ports by setting the IOSE</li> <li>bit to 1.</li> </ul>
0	P20DDR	0	W	To ensure normal accesses to an external space, port 2 pins should not be set as an on-chip peripheral module output pin when port 2 pins are used as address output pins.
				Modes 2 and 3 (EXPE = 0):
			The corresponding port 2 pins are output ports when P2DDR bits are set to 1, and input ports when cleared to 0.	

# 7.3.2 Port 2 Data Register (P2DR)

P2DR stores output data for port 2.

Bit	Bit Name	Initial Value	R/W	Description
7	P27DR	0	R/W	If a port 2 read is performed while P2DDR bits are
6	P26DR	0	R/W	set to 1, the P2DR values are read directly, regardless of the actual pin states. If a port 2 read
5	P25DR	0	R/W	is performed while P2DDR bits are cleared to 0,
4	P24DR	0	R/W	the pin states are read.
3	P23DR	0	R/W	
2	P22DR	0	R/W	
1	P21DR	0	R/W	
0	P20DR	0	R/W	

# 7.3.3 Port 2 Pull-Up MOS Control Register (P2PCR)

P2PCR controls the port 2 on-chip input pull-up MOSs.

Bit	Bit Name	Initial Value	R/W	Description
7	P27PCR	0	R/W	In modes 2 and 3, the input pull-up MOS is turned
6	P26PCR	0	R/W	on when a P2PCR bit is set to 1 in the input port state.
5	P25PCR	0	R/W	— oldio.
4	P24PCR	0	R/W	
3	P23PCR	0	R/W	
2	P22PCR	0	R/W	
1	P21PCR	0	R/W	
0	P20PCR	0	R/W	

### 7.3.4 Pin Functions

To ensure normal access to external space, P27 should not be set as an on-chip peripheral module output pin when port 2 pins are used as address output pins.

P27/A15, P26/A14, P25/A13, and P24/A12
 Pin functions are switched as shown below according to the combination of the IOSE bit in SYSCR, P27DDR bit, and operating mode.

Operating Mode	Mode 1	Mode 2, 3 (EXPE = 1) Mod				(EXPE = 0)
P2nDDR	_	0	1		0	1
IOSE	_	_	0	1	_	_
Pin Function	A15 to A12 output pins	P27 to P24 input pins	A15 to A12 output pins	P27 to P24 input pins	P27 to P24 input pins	P27 to P24 input pins

[Legend]

n = 7 to 4

P23/A11, P22/A10, P21/A9, and P20/A8

Pin functions are switched as shown below according to the combination of the P2nDDR bit and operating mode.

Operating Mode	Mode 1	Mode 2, 3	(EXPE = 1)	Mode 2, 3	(EXPE = 0)
P2nDDR	_	0	1	0	1
Pin Function	A11 to A8 output pins	P23 to P20 input pins	A11 to A8 output pins	P23 to P20 input pins	P23 to P20 input pins

[Legend]

n = 3 to 0

# 7.3.5 Port 2 Input Pull-Up MOS

Port 2 has an on-chip input pull-up MOS function that can be controlled by software. This input pull-up MOS function can be specified as on or off on a bit-by-bit basis.

Table 7.4 summarizes the input pull-up MOS states.

**Table 7.4** Input Pull-Up MOS States (Port 2)

Mode	Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1	Off	Off	Off	Off
2, 3	<del>_</del>		On/Off	On/Off

[Legend]

Off: Input pull-up MOS is always off.

On/Off: On when the pin is in the input state, P2DDR = 0, and P2PCR = 1; otherwise off.

### 7.4 Port 3

Port 3 is an 8-bit I/O port. Port 3 pins also function as a bidirectional data bus. Port 3 functions change according to the operating mode. Port 3 has the following registers.

- Port 3 data direction register (P3DDR)
- Port 3 data register (P3DR)
- Port 3 pull-up MOS control register (P3PCR)

## 7.4.1 Port 3 Data Direction Register (P3DDR)

P3DDR specifies input or output for the pins of port 3 on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	P37DDR	0	W	Modes 1, 2, and 3 (EXPE = 1)
6	P36DDR	0	W	The input/output direction specified by P3DDR is
5	P35DDR	0	W	ignored, and pins automatically function as data I/O pins.
4	P34DDR	0	W	Modes 2 and 3 (EXPE = 0)
3	P33DDR	0	W	The corresponding port 3 pins are output ports
2	P32DDR	0	W	when P3DDR bits are set to 1, and input ports
1	P31DDR	0	W	when cleared to 0.
0	P30DDR	0	W	

### 7.4.2 Port 3 Data Register (P3DR)

P3DR stores output data of port 3.

Bit	Bit Name	Initial Value	R/W	Description
7	P37DR	0	R/W	If a port 3 read is performed while P3DDR bits are set to 1, the P3DR values are read directly, regardless of the actual pin states. If a port 3 read is performed while P3DDR bits are cleared to 0, the pin states are read.
6	P36DR	0	R/W	
5	P35DR	0	R/W	
4	P34DR	0	R/W	
3	P33DR	0	R/W	
2	P32DR	0	R/W	
1	P31DR	0	R/W	_
0	P30DR	0	R/W	_

### 7.4.3 Port 3 Pull-Up MOS Control Register (P3PCR)

P3PCR controls the port 3 on-chip input pull-up MOSs on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	P37PCR	0	R/W	In modes 2 and 3 (when EXPE = 0), the input pull-
6	P36PCR	0	R/W	Tup MOS is turned on when a P3PCR bit is set to 1 . in the input port state.  The input pull-up MOS function cannot be used when the host interface is enabled.
5	P35PCR	0	R/W	
4	P34PCR	0	R/W	
3	P33PCR	0	R/W	_
2	P32PCR	0	R/W	_
1	P31PCR	0	R/W	_
0	P30PCR	0	R/W	_

### 7.4.4 Pin Functions

P37/D15\*, P36/D14\*, P35/D13\*, P34/D12\*, P33/D11\*, P32/D10\*, P31/D9\*, and P30/D8\*
 Pin functions are switched as shown below according to the combination of the P3nDDR bit and operating mode.

Operating Mode	Mode 1, 2, 3 (EXPE = 1)	Mode 2, 3 (EXPE = 0)		
P3nDDR	_	0	1	
Pin Function	D15 to D8* input/output pins	P37 to P30 input pins	P37 to P30 output pins	

Note: n = 7 to 0

## 7.4.5 Port 3 Input Pull-Up MOS

Port 3 has an on-chip input pull-up MOS function that can be controlled by software. This input pull-up MOS function can be specified as on or off on a bit-by-bit basis.

Table 7.5 summarizes the input pull-up MOS states.

<sup>\*</sup> D7 to D0 in the H8S/2134B are equivalent of D15 to D8 in the H8S/2144B.

Table 7.5 Input Pull-Up MOS States (Port 3)

Mode	Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1, 2, 3 (EXPE = 1	) Off	Off	Off	Off
2, 3 (EXPE = 0)	<del></del>		On/Off	On/Off

## [Legend]

Off: Input pull-up MOS is always off.

On/Off: On when the pin is in the input state, P3DDR = 0, and P3PCR = 1; otherwise off.

#### 7.5 Port 4

Port 4 is an 8-bit I/O port. Port 4 pins also function as PWMX output pins, TMR\_0 and TMR\_1 I/O pins, SCI\_2 I/O pins, and IrDA interface I/O pins. Port 4 pin functions are the same in all operating modes. Port 4 has the following registers.

- Port 4 data direction register (P4DDR)
- Port 4 data register (P4DR)

## 7.5.1 Port 4 Data Direction Register (P4DDR)

P4DDR specifies input or output for the pins of port 4 on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	P47DDR	0	W	When a bit in P4DDR is set to 1, the corresponding
6	P46DDR	0	W	<ul> <li>pin functions as an output port, and when cleared</li> <li>to 0, as an input port.</li> </ul>
5	P45DDR	0	W	— As 14-bit PWM and SCI 2 are initialized in softw
4	P44DDR	0	W	standby mode, the pin states are determined by the
3	P43DDR	0	W	TMR_0, TMR_1, P4DDR, and P4DR specifications.
2	P42DDR	0	W	<del>_</del>
1	P41DDR	0	W	<del></del>
0	P40DDR	0	W	<del>_</del>

## 7.5.2 Port 4 Data Register (P4DR)

P4DR stores output data for port 4.

Bit	Bit Name	Initial Value	R/W	Description
7	P47DR	0	R/W	If a port 4 read is performed while P4DDR bits are
6	P46DR	0	R/W	set to 1, the P4DR values are read directly, regardless of the actual pin states. If a port 4 read
5	P45DR	0	R/W	is performed while P4DDR bits are cleared to 0, the
4	P44DR	0	R/W	pin states are read.
3	P43DR	0	R/W	-
2	P42DR	0	R/W	-
1	P41DR	0	R/W	-
0	P40DR	0	R/W	_

#### 7.5.3 Pin Functions

#### P47/PWX1

Pin functions are switched as shown below according to the combination of the OEB bit in DACR of the 14-bit PWM and the P47DDR bit.

OEB		1	
P47DDR	0 1		_
Pin Function	P47 input pin	P47 output pin	PWX1 output pin

#### P46/PWX0

Pin functions are switched as shown below according to the combination of the OEA bit in DACR of the 14-bit PWM and the P46DDR bit.

OEA		1	
P46DDR	0 1		_
Pin Function	P46 input pin	P46 output pin	PWX0 output pin

#### P45/TMRI1

Pin functions are switched as shown below according to the P45DDR bit.

P45DDR	0	1	
Pin Function	P45 input pin	P45 output pin	
	TMRI1 input pin*		

Note: \* When bits CCLR1 and CCLR0 in TCR1 of TMR\_1 are set to 1, this pin is used as the TMRI1 input pin.

#### P44/TMO1

Pin functions are switched as shown below according to the combination of the OS3 to OS0 bits in TCSR of TMR\_1 and the P44DDR bit.

OS3 to OS0	Al	Not all 0	
P44DDR	0 1		_
Pin Function	P44 input pin P44 output pin		TMO1 output pin

#### • P43/TMCI1

Pin functions are switched as shown below according to the P43DDR bit.

P43DDR	0	1	
Pin Function	P43 input pin	P43 output pin	
	TMCI1 input pin*		

Note: \* When the external clock is selected by bits CKS2 to CKS0 in TCR1 of TMR\_1, this pin is used as the TMCI1 input pin.

#### P42/TMRI0/SCK2

Pin functions are switched as shown below according to the combination of the CKE1 and CKE0 bits in SCR of SCI 2, the  $C/\overline{A}$  bit in SMR of SCI 2, and the P42DDR bit.

CKE1		0			
C/A		0	1	_	
CKE0	(	0	1	_	_
P42DDR	0 1		_	_	_
Pin Function	P42 input pin	P42 output pin	SCK2 output pin	SCK2 output pin	SCK2 input pin
	TMRI0 input pin*				

Note: \* When bits CCLR1 and CCLR0 in TCR0 of TMR\_0 are set to 1, this pin is used as the TMRI0 input pin.

#### P41/TMO0/RxD2/IrRxD

Pin functions are switched as shown below according to the combination of the OS3 to OS0 bits in TCSR of TMR0, the RE bit in SCR of SCI 2 and the P41DDR bit.

OS3 to OS0		Not all 0		
RE	0		1	0
P41DDR	0 1		_	_
Pin Function	P41 input pin	P41 output pin	RxD2/IrRxD input pin	TMO0 output pin

Note: \* When this pin is used as the TMO0 output pin, bit RE in SCR of SCI\_2 must be cleared to 0.

#### P40/TMCI0/TxD2/IrTxD

Pin functions are switched as shown below according to the combination of the TE bit in SCR of SCI\_2 and the P40DDR bit.

TE	0 1		
P40DDR	0 1		_
Pin Function	P40 input pin	P40 output pin	TxD2/IrTxD output pin
	TMCI0 input pin*		

Note: \* When an external clock is selected with bits CKS2 to CKS0 in TCR0 of TMR\_0, this pin is used as the TMCI0 input pin.

## 7.6 Port 5

Port 5 is a 3-bit I/O port. Port 5 pins also function as SCI\_0 I/O pins. Port 5 has the following registers.

- Port 5 data direction register (P5DDR)
- Port 5 data register (P5DR)

## 7.6.1 Port 5 Data Direction Register (P5DDR)

P5DDR specifies input or output for the pins of port 5 on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	_	All 1	_	Reserved
to 3				The initial value must not be changed.
2	P52DDR	0	W	The corresponding port 5 pins are output ports
1	P51DDR	0	W	when P5DDR bits are set to 1, and input ports when cleared to 0. As SCI 0 is initialized in
0	P50DDR	0	W	software standby mode, the pin states are determined by the P5DDR and P5DR specifications.

## 7.6.2 Port 5 Data Register (P5DR) P3PCR

P5DR stores output data for port 5 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	_	All 1	_	Reserved
to 3				The initial value must not be changed.
2	P52DR	0	R/W	If a port 5 read is performed while P5DDR bits are
1	P51DR	0	R/W	set to 1, the P5DR values are read directly, regardless of the actual pin states. If a port 5 read
0	P50DR	0	R/W	is performed while P5DDR bits are cleared to 0, the pin states are read.

#### 7.6.3 Pin Functions

#### P52/SCK0

Pin functions are switched as shown below according to the combination of the CKE1 and CKE0 bits in SCR of SCI\_0, the  $C/\overline{A}$  bit in SMR of SCI\_0, the ICE bit in ICCR of IIC\_0, and the P52DDR bit.

CKE1			1		
C/A		0	1	_	
CKE0	(	)	1	_	_
P52DDR	0	1	_	_	_
Pin Function	P52 input pin	P52 output pin	SCK0 output pin	SCK0 output pin	SCK0 input pin

#### P51/RxD0

Pin functions are switched as shown below according to the combination of the RE bit in SCR of SCI\_0 and the P51DDR bit.

RE	(	1	
P51DDR	0	1	_
Pin Function	P51 input pin	P51 output pin	RxD0 input pin

#### P50/TxD0

Pin functions are switched as shown below according to the combination of the TE bit in SCR of SCI 0 and the P50DDR bit.

TE	(	1	
P50DDR	0 1		_
Pin Function	P50 input pin	P50 output pin	TxD0 output pin

#### 7.7 Port 6

Port 6 is an 8-bit I/O port. Port 6 pins also function as the FRT I/O pins, the TMR\_Y input pin, key-sense interrupt input pins, extended A/D converter input pins, and external interrupt input pins. The port 6 input level can be switched in four stages. Port 6 pin functions are the same in all operating modes. Port 6 has the following registers.

- Port 6 data direction register (P6DDR)
- Port 6 data register (P6DR)
- Port 6 pull-up MOS control register (KMPCR6)
- System control register 2 (SYSCR2)

## 7.7.1 Port 6 Data Direction Register (P6DDR)

P6DDR specifies input or output for the pins of port 6 on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	P67DDR	0	W	The corresponding port 6 pins are output ports
6	P66DDR	0	W	<ul><li>when P6DDR bits are set to 1, and input ports</li><li>when cleared to 0.</li></ul>
5	P65DDR	0	W	— when dicarca to 0.
4	P64DDR	0	W	<del></del>
3	P63DDR	0	W	<del></del>
2	P62DDR	0	W	<del></del>
1	P61DDR	0	W	<del></del>
0	P60DDR	0	W	_

## 7.7.2 Port 6 Data Register (P6DR)

P6DR stores output data for port 6.

Bit	Bit Name	Initial Value	R/W	Description
7	P67DR	0	R/W	If a port 6 read is performed while P6DDR bits are
6	P66DR	0	R/W	set to 1, the P6DR values are read directly, regardless of the actual pin states. If a port 6 read
5	P65DR	0	R/W	is performed while P6DDR bits are cleared to 0,
4	P64DR	0	R/W	the pin states are read.
3	P63DR	0	R/W	
2	P62DR	0	R/W	
1	P61DR	0	R/W	
0	P60DR	0	R/W	

## 7.7.3 Port 6 Pull-Up MOS Control Register (KMPCR)

KMPCR controls the port 6 on-chip input pull-up MOSs on a bit-by-bit basis. To make the settings of this register valid, clear bit MSTP2 in MSTPCRL to 0.

Bit	Bit Name	Initial Value	R/W	Description
7	KM7PCR	0	R/W	The input pull-up MOS is turned on when a
6	KM6PCR	0	R/W	<ul> <li>KMPCR bit is set to 1 while the corresponding</li> <li>P6DDR bit is cleared to 0 (input port setting).</li> </ul>
5	KM5PCR	0	R/W	= 1 05511 bit to dicarca to a (input port octaing).
4	KM4PCR	0	R/W	
3	KM3PCR	0	R/W	_
2	KM2PCR	0	R/W	_
1	KM1PCR	0	R/W	_
0	KM0PCR	0	R/W	_

## 7.7.4 System Control Register 2 (SYSCR2)

SYSCR2 controls the signal levels input on port 6 and current specifications.

Bit	Bit Name	Initial Value	R/W	Description	
7	KWUL1	0	R/W	Key Wakeup Level 1 and 0	
6	KWUL0	0	R/W	Selects the input level of port 6. The input levels of other functions of the multiplexed pin are also decided by these bits.	
				00: Normal input level	
				01: Input level 1	
				10: Input level 2	
				11: Input level 3	
5	P6PUE	0	R/W	Port 6 Input Pull-Up MOS Extra	
				Selects the specification of the input pull-up MOS in current driving ability.	
				0: Normal current specification	
				1: Limited current specification	
4	_	0	_	Reserved	
				Do not write 1 to this bit.	
3	_	All 0	R/W	N Reserved	
to 0				Do not write 1 to this bit	

#### 7.7.5 Pin Functions

## P67/CIN7/KIN7/IRQ7

Pin functions are switched as shown below according to the P67DDR bit.

P67DDR	0	1		
Pin Function	P67 input pin	P67 output pin		
	IRQ7 input pin, KIN7 input pin, CIN7 input pin*			

Note: \* This pin is used as the IRQ7 input pin when bit IRQ7E is set to 1 in IER. It can always be used as the KIN7 or CIN7 input pin.

## • P66/FTOB/CIN6/KIN6/IRQ6

Pin functions are switched as shown below according to the combination of the OEB bit in TOCR of the FRT and the P66DDR bit.

OEB	0	-	1		
P66DDR	0	1	_		
Pin Function	P66 input pin	P66 output pin	FTOB output pin		
	IRQ6 input pin, KIN6 input pin, CIN6 input pin*				

Note: \* This pin is used as the IRQ6 input pin when bit IRQ6E is set to 1 in IER while the KMIMR6 bit in KMIMR is 0. It can always be used as the KIN6 or CIN6 input pin.

#### • P65/FTID/CIN5/KIN5

P65DDR	0	1		
Pin Function	P65 input pin	P65 output pin		
	FTID input pin, KIN5 input pin, CIN5 input pin*			

Note: \* This pin can always be used as the FTID, KIN5, or CIN5 input pin.

#### • P64/FTIC/CIN4/KIN4

Pin functions are switched as shown below according to the P64DDR bit.

P64DDR	0	1		
Pin Function	P64 input pin	P64 output pin		
	FTIC input pin, KIN4 input pin, CIN4 input pin*			

Note: \* This pin can always be used as the FTIC, KIN4, or CIN4 input pin.

## • P63/FTIB/CIN3/KIN3

P63DDR	0	1				
Pin Function	P63 input pin	P63 output pin				
	FTIB input pin, KIN3 input pin, CIN3 input pin*					

Note: \* This pin can always be used as the FTIB, KIN3, or CIN3 input pin.

#### P62/FTIA/CIN2/KIN2/TMIY

P62DDR	0	1			
Pin Function	P62 input pin	P62 output pin			
	FTIA input pin, TMIY input pin, KIN2 input pin, CIN2 input pin*				

Note: \* This pin can always be used as the FTIA, TMIY, KIN2, or CIN2 input pin.

#### • P61/FTOA/CIN1/KIN1

Pin functions are switched as shown below according to the combination of the OEA bit in TOCR of the FRT and the P61DDR bit.

OEA	0		1			
P61DDR	0	1	_			
Pin Function	P61 input pin	P61 output pin	FTOA output pin			
	KIN1 input pin, CIN1 input pin*					

Note: \* This pin can always be used as the KIN1 or CIN1 input pin.

#### • P60/FTCI/CIN0/KIN0

P60DDR	0	1				
Pin Function	P60 input pin	P60 output pin				
	FTCI input pin, KINO input pin, CINO input pin*					

Note: \* This pin is used as the FTCI input pin when an external clock is selected with bits CKS1 and CKS0 in TCR of the FRT. It can always be used as the KINO or CINO input pin.

## 7.7.6 Port 6 Input Pull-Up MOS

Port 6 has an on-chip input pull-up MOS function that can be controlled by software. This input pull-up MOS function can be specified as on or off on a bit-by-bit basis.

The input pull-up MOS current specification can be changed by means of the P6PUE bit. When a pin is designated as an on-chip peripheral module output pin, the input pull-up MOS is always off.

Table 7.6 summarizes the input pull-up MOS states.

**Table 7.6** Input Pull-Up MOS States (Port 6)

Mode	Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1, 2, 3	Off	Off	On/Off	On/Off

[Legend]

Off: Input pull-up MOS is always off.

On/Off: On when the pin is in the input state, P6DDR = 0, and KMPCR = 1; otherwise off.

#### 7.8 Port 7

Port 7 is an 8-bit input only port. Port 7 pins also function as the A/D converter analog input pins and D/A converter analog output pins. Port 7 functions are the same in all operating modes. Port 7 has the following register.

• Port 7 input data register (P7PIN)

#### 7.8.1 Port 7 Input Data Register (P7PIN)

P7PIN reflects the pin states of port 7.

Bit	Bit Name	Initial Value	R/W	Description
7	P77PIN	Undefined*	R	When a P7PIN read is performed, the pin states
6	P76PIN	Undefined*	R	are always read. P7PIN has the same address as PBDDR; if a write is performed, data will be written
5	P75PIN	Undefined*	R	into PBDDR and the port B setting will be changed.
4	P74PIN	Undefined*	R	_
3	P73PIN	Undefined*	R	_
2	P72PIN	Undefined*	R	_
1	P71PIN	Undefined*	R	<del>-</del>
0	P70PIN	Undefined*	R	

Note: \* Determined by the pin states of P77 to P70.

#### 7.8.2 Pin Functions

#### • P77/AN7/DA1

Pin functions are switched as shown below according to the combination of the DAE bit in DACR of the D/A converter and the DAOE1 bit.

DAOE1	(	1			
DAE	0	_			
Pin Function	P77 input pin DA1 input pin		DA1 output pin		
	AN7 input pin*				

Note: \* This pin can always be used as the AN7 input pin.

#### P76/AN6/DA0

Pin functions are switched as shown below according to the combination of the DAE bit in DACR of the D/A converter and the DAOE0 bit.

DAOE0	(	1			
DAE	0	_			
Pin Function	P76 input pin DA0 output pin		DA0 output pin		
	AN6 input pin*				

Note: \* This pin can always be used as the AN6 input pin.

• P75/AN5, P74/AN4, P73/AN3, P72/AN2, P71/AN1, P70/AN0

Pin Function	P75 to P70 input pins
	AN5 to AN0 input pin*

Note: \* This pin can always be used as the AN5 to AN0 input pins.

## 7.9 Port 8

Port 8 is an 8-bit I/O port. Port 8 pins also function as SCI\_1 I/O pins and interrupt input pins. Port 8 pin functions are the same in all operating modes. Port 8 has the following registers.

- Port 8 data direction register (P8DDR)
- Port 8 data register (P8DR)

## 7.9.1 Port 8 Data Direction Register (P8DDR)

P8DDR specifies input or output for the pins of port 8 on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	_	1	_	Reserved
				The initial value must not be changed.
6	P86DDR	0	W	P8DDR has the same address as PBPIN, and if
5	P85DDR	0	W	read, the port B state will be returned. (Available — only in the H8S/2144B.)
4	P84DDR	0	W	The corresponding port 8 pins are output ports
3	P83DDR	0	W	when P8DDR bits are set to 1, and input ports
2	P82DDR	0	W	when cleared to 0.
1	P81DDR	0	W	
0	P80DDR	0	W	

## 7.9.2 Port 8 Data Register (P8DR)

P8DR stores output data for the port 8 pins (P86 to P80).

Bit	Bit Name	Initial Value	R/W	Description
7	_	1	_	Reserved
				The initial value must not be changed.
6	P86DR	0	R/W	If a port 8 read is performed while P8DDR bits are
5	P85DR	0	R/W	set to 1, the P8DR values are read directly, regardless of the actual pin states. If a port 8 read
4	P84DR	0	R/W	is performed while P8DDR bits are cleared to 0,
3	P83DR	0	R/W	the pin states are read.
2	P82DR	0	R/W	_
1	P81DR	0	R/W	_
0	P80DR	0	R/W	_

#### 7.9.3 Pin Functions

## P86/IRQ5/SCK1

Pin functions are switched as shown below according to the combination of the CKE1 and CKE0 bits in SCR of SCI\_1, the  $C/\overline{A}$  bit in SMR of SCI\_1, and the P86DDR bit.

CKE1		1			
C/A		0	1	_	
CKE0	(	)	1	_	_
P86DDR	0	1	_	_	_
Pin Function	P86 input pin P86 output pin		SCK1 output pin	SCK1 output pin	SCK1 input pin

Note: \* When the IRQ5E bit in IER is set to 1, this pin is used as the IRQ5 input pin.

## • P85/<del>IRQ4</del>/RxD1

Pin functions are switched as shown below according to the combination of the RE bit in SCR of SCI\_1 and the P85DDR bit.

RE	(	1		
P85DDR	0 1		_	
Pin Function	P85 input pin P85 output pin		RxD1 input pin	
	IRQ4 input pin*			

Note: \* When the IRQ4E bit in IER is set to 1, this pin is used as the IRQ4 input pin.

## P84/IRQ3/TxD1

Pin functions are switched as shown below according to the combination of the TE bit in SCR of SCI\_1 and the P84DDR bit.

TE	(	1		
P84DDR	0	_		
Pin Function	P84 input pin	TxD1 output pin		
	ĪRQ3 input pin*			

Note: \* When the IRQ3E bit in IER is set to 1, this pin is used as the IRQ3 input pin.

## • P83

Pin functions are switched as shown below according to the P83DDR bit.

P83DDR	0	1
Pin Function	P83 input pin	P83 output pin

## • P82

Pin functions are switched as shown below according to the P82DDR bit.

P82DDR	0	1
Pin Function	P82 input pin	P82 output pin

# P81 Pin functions are switched as shown below according to the P81DDR bit.

P81DDR	0	1
Pin Function	P81 input pin	P81 output pin

# P80 Pin functions are switched as shown below according to the P80DDR bit.

P80DDR	0	1	
Pin Function	P80 input pin	P80 output pin	

#### 7.10 Port 9

Port 9 is an 8-bit I/O port. Port 9 pins also function as external interrupt input pins, the A/D converter input pin, the subclock input pin, bus control signal I/O pins, and the system clock  $(\phi)$  output pin. Port 9 has the following registers.

- Port 9 data direction register (P9DDR)
- Port 9 data register (P9DR)

## 7.10.1 Port 9 Data Direction Register (P9DDR)

P9DDR specifies input or output for the pins of port 9 on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	P97DDR	0	W	P9DDR is initialized to H'40 (mode 1) or H'00 (modes 2
6	P96DDR	1/0*	W	and 3).
5	P95DDR	0	W	Modes 1, 2, and 3 (EXPE = 1):
4	P94DDR	0	W	<ul> <li>─ Pin P97 functions as a bus control input (WAIT) or an I/O</li> <li>_ port according to the wait mode setting. When P97</li> </ul>
3	P93DDR	0	W	functions as an I/O port, it becomes an output port when
2	P92DDR	0	W	P97DDR is set to 1, and an input port when P97DDR is cleared to 0.
1	P91DDR	0	W	***************************************
0	P90DDR	0	W	— Pin P96 functions as the
				Pins P95 to P93 automatically become bus control outputs $(\overline{AS/IOS}, \overline{HWR}, \overline{WR}, \overline{RD})$ , regardless of the input/output direction indicated by P95DDR to P93DDR.
				Pins P92 and P91 become output ports when P92DDR and P91DDR are set to 1, and input ports when P92DDR and P91DDR are cleared to 0.
				When the ABW bit in WSCR is cleared to 0 (clearing to 0 is prohibited in the H8S/2134B), pin P90 becomes a bus control output (LWR), regardless of the input/output direction indicated by P90DDR. When the ABW bit is 1, pin P90 becomes an output port if P90DDR is set to 1, and an input port if P90DDR is cleared to 0.
				Modes 2 and 3 (EXPE = 0):
				When the corresponding P9DDR bits are set to 1, pin P96 functions as the $\phi$ output pin and pins P97 and P95 to P90 become output ports. When P9DDR bits are cleared to 0, the corresponding pins become input ports.

Note: \* The initial value of P96DDR is 1 (mode 1) or 0 (modes 2 and 3).

## 7.10.2 Port 9 Data Register (P9DR)

P9DR stores output data for the port 9 pins.

Bit	Bit Name	Initial Value	R/W	Description
7	P97DR	0	R/W	With the exception of P96, if a port 9 read is
6	P96DR	Undefined*	R	performed while P9DDR bits are set to 1, the P9DR values are read directly, regardless of the
5	P95DR	0	R/W	actual pin states. If a port 9 read is performed while
4	P94DR	0	R/W	P9DDR bits are cleared to 0, the pin states are — read.
3	P93DR	0	R/W	
2	P92DR	0	R/W	— For P96, the pin state is always read.
1	P91DR	0	R/W	<del></del>
0	P90DR	0	R/W	<del></del>

Note: \* The initial value of bit 6 is determined according to the P96 pin state.

#### 7.10.3 Pin Functions

#### P97/WAIT

Pin functions are switched as shown below according to the combination of operating mode, the WMS1 bit in WSCR, and the P97DDR bit.

Operating Mode	Modes 1, 2, 3 (EXPE = 1)			Modes 2, 3	(EXPE = 0)
WMS1	(	)	1	_	_
P97DDR	0 1		_	0	1
Pin Function	P97 input pin	P97 output pin	WAIT input pin	P97 input pin	P97 output pin

## ▶ P96/ø/EXCL

Pin functions are switched as shown below according to the combination of the EXCLE bit in LPWRCR and the P96DDR bit.

P96DDR	(	1	
EXCLE	0 1		0
Pin Function	P96 input pin	P96 input pin EXCL input pin	

Note: \* When this pin is used as the EXCL input pin, P96DDR should be cleared to 0.

#### P95/AS/IOS

Pin functions are switched as shown below according to the combination of operating mode, the IOSE bit in SYSCR, and the P95DDR bit.

Operating Mode	Modes 1, 2,	3 (EXPE = 1)	Modes 2, 3	(EXPE = 0)
P95DDR	_	_	0	1
IOSE	0 1		_	_
Pin Function	AS output pin	IOS output pin	P95 input pin	P95 output pin

#### P94/HWR\*

Pin functions are switched as shown below according to the combination of operating mode and the P94DDR bit.

Operating Mode	Modes 1, 2, 3 (EXPE = 1)	Modes 2, 3 (EXPE = 0)	
P94DDR	_	0	1
Pin Function	HWR* output pin	P94 input pin	P94 output pin

Note: \* The WR pin in the H8S/2134B

## P93/RD

Pin functions are switched as shown below according to the combination of operating mode and the P93DDR bit.

Operating Mode	Modes 1, 2, 3 (EXPE = 1) Modes 2, 3 (EXPE = 0)		
P93DDR	_	0	1
Pin Function	RD output pin	P93 input pin	P93 output pin

## P92/IRQ0

P92DDR	0	1			
Pin Function	P92 input pin	P92 output pin			
	IRQ0 input pin*				

Note: \* When bit IRQ0E in IER is set to 1, this pin is used as the IRQ0 input pin.

## P91/IRQ1

P91DDR	0	1				
Pin Function	P91 input pin	P91 output pin				
	IRQ1 input pin*					

Note: \* When bit IRQ1E in IER is set to 1, this pin is used as the IRQ1 input pin.

## • P90/LWR\*2/IRQ2/ADTRG

Pin functions are switched as shown below according to the combination of operating mode, the ABW bit in WSCR, and the P90DDR bit.

Operating Mode	Mod	es 1, 2, 3 (EXPE	Modes 2, 3	(EXPE = 0)	
ABW	0		1	_	
P90DDR	_	0	1	0	1
Pin Function	LWR*2 output	P90 input pin P90 output pin		P90 input pin	P90 output pin
	pin	IRQ2 input pin, ADTRG input pin*			

Note: 1. When the ABW bit in WSCR is set to 1 in mode 1, 2, or 3 (EXPE = 1), or the IRQ2E bit in IER is set to 1 in mode 2 or 3 (EXPE = 0), this pin is used as the IRQ2 input pin.

When TRGS1 and TRGS0 in ADCR of the A/D converter are both set to 1, this pin is used as the ADTRG input pin.

2. The  $\overline{\text{LWR}}$  pin is not available in the H8S/2134B. Do not clear the ABW bit in WSCR to 0.

## 7.11 Port A (Only for H8S/2144B)

Port A is an 8-bit I/O port. Port A pins also function as key-sense interrupt input pins, extended A/D converter input pins, and address output pins. Port A pin functions change according to the operating mode. Port A input/output operates by VccB power independent from the Vcc power. Up to 5 V can be applied to port A pins if VccB power is 5 V. Port A has the following registers. PADDR and PAPIN have the same address.

- Port A data direction register (PADDR)
- Port A output data register (PAODR)
- Port A input data register (PAPIN)

#### 7.11.1 Port A Data Direction Register (PADDR)

PADDR specifies input or output for the pins of port A on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7DDR	0	W	In mode 1, 2 (EXPE = 0), or 3:
6	PA6DDR	0	W	The corresponding port A pins are output ports
5	PA5DDR	0	W	when PADDR bits are set to 1, and input ports when cleared to 0.
4	PA4DDR	0	W	_ In mode 2 (EXPE = 1):
3	PA3DDR	0	W	The corresponding port A pins are address output
2	PA2DDR	0	W	when PADDR bits are set to 1, and input ports
1	PA1DDR	0	W	when cleared to 0. The port A pins changes from the address I/O ports to output ports by setting the
0	PA0DDR	0	W	IOSE bit to 1.
				PADDR has the same address as PAPIN, if read, port A status is returned.

## 7.11.2 Port A Output Data Register (PAODR)

PAODR stores output data for port A.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7ODR	0	R/W	PAODR can always be read or written to,
6	PA6ODR	0	R/W	regardless of the contents of PADDR.
5	PA5ODR	0	R/W	
4	PA4ODR	0	R/W	
3	PA3ODR	0	R/W	
2	PA2ODR	0	R/W	
1	PA10DR	0	R/W	
0	PA0ODR	0	R/W	

## 7.11.3 Port A Input Data Register (PAPIN)

PAPIN indicates the port A state.

Bit	Bit Name	Initial Value	R/W	Description
7	PA7PIN	Undefined*	R	Reading PAPIN always returns the pin states.
6	PA6PIN	Undefined*	R	PAPIN has the same address as PADDR. If a write is performed, the port A settings will change.
5	PA5PIN	Undefined*	R	- to portormou, the port / country will orlaringe.
4	PA4PIN	Undefined*	R	<del>-</del>
3	PA3PIN	Undefined*	R	<del>-</del>
2	PA2PIN	Undefined*	R	<del>-</del>
1	PA1PIN	Undefined*	R	<del>-</del>
0	PA0PIN	Undefined*	R	_

Note: \* The initial value is determined according to the PA7 to PA0 pin states.

#### 7.11.4 Pin Functions

#### PA7/A23/KIN15/CIN15

Pin functions are switched as shown below according to the combination of operating mode, the IOSE bit in SYSCR, and the PA7DDR bit.

Operating Mode	Modes 1, 2 (EXPE = 0), 3		Mode 2 (EXPE = 1)		
PA7DDR	0	1	0	1	
IOSE	_	_	_	0	1
Pin Function	PA7 input pin	PA7 output pin	PA7 input pin	A23 output pin	PA7 output pin
	KIN15 input pin, CIN15 input pin*				

Note: \* When the IICS bit in STCR is set to 1, this pin is an NMOS open-drain output, and has direct bus drive capability. This pin can always be used as the KIN15 or CIN15 input pin.

#### PA6/A22/KIN14/CIN14

Pin functions are switched as shown below according to the combination of operating mode, the IOSE bit in SYSCR, and the PA6DDR bit.

Operating Mode	Modes 1, 2 (EXPE = 0), 3		Mode 2 (EXPE = 1)		
PA6DDR	0	1	0	1	
IOSE	_	_	_	0	1
Pin Function	PA6 input pin	PA6 output pin	PA6 input pin	A22 output pin	PA6 output pin
	KIN14 input pin, CIN14 input pin*				

Note: \* When the IICS bit in STCR is set to 1, this pin is an NMOS open-drain output, and has direct bus drive capability. This pin can always be used as the KIN14 or CIN14 input pin.

#### PA5/A21/KIN13/CIN13

Pin functions are switched as shown below according to the combination of operating mode, the IOSE bit in SYSCR, and the PA5DDR bit.

Operating Mode	Modes 1, 2 (EXPE = 0), 3		Mode 2 (EXPE = 1)		
PA5DDR	0	1	0	1	
IOSE	_	_	_	0	1
Pin Function	PA5 input pin	PA5 output pin	PA5 input pin	A21 output pin	PA5 output pin
	KIN13 input pin, CIN13 input pin*				

Note: \* When the IICS bit in STCR is set to 1, this pin is an NMOS open-drain output, and has direct bus drive capability. This pin can always be used as the KIN13, or CIN13 input pin.

#### PA4/A20/KIN12/CIN12

Pin functions are switched as shown below according to the combination of operating mode, the IOSE bit in SYSCR, and the PA4DDR bit.

Operating Mode	Modes 1, 2 (EXPE = 0), 3		Mode 2 (EXPE = 1)		
PA4DDR	0	1	0	1	
IOSE	_	_	_	0	1
Pin Function	PA4 input pin	PA4 output pin	PA4 input pin	A20 output pin	PA4 output pin
	KIN12 input pin, CIN12 input pin*				

Note: \* When the IICS bit in STCR is set to 1, this pin is an NMOS open-drain output, and has direct bus drive capability. This pin can always be used as the KIN12 or CIN12 input pin.

#### PA3/A19/KIN11/CIN11

Pin functions are switched as shown below according to the combination of operating mode, the IOSE bit in SYSCR, and the PA3DDR bit.

Operating Mode	Modes 1, 2 (EXPE = 0), 3		Mode 2 (EXPE = 1)		
PA3DDR	0	1	0	1	
IOSE	_	_	_	0	1
Pin Function	PA3 input pin	PA3 output pin	PA3 input pin	A19 output pin	PA3 output pin
	KIN11 input pin, CIN11 input pin*				

Note: \* This pin can always be used as the KIN11 or CIN11 input pin.

## • PA2/A18/KIN10/CIN10

Pin functions are switched as shown below according to the combination of operating mode, the IOSE bit in SYSCR, and the PA2DDR bit.

Operating Mode	Modes 1, 2 (	EXPE = 0), 3	Mode 2 (EXPE = 1)		
PA2DDR	0 1		0	1	
IOSE	_	_	_	0	1
Pin Function	PA2 input pin			A18 output pin	PA2 output pin
	KIN10 input pin, CIN10 input pin*				

Note: \* This pin can always be used as the KIN10 or CIN10 input pin.

## • PA1/A17/KIN9/CIN9

Pin functions are switched as shown below according to the combination of operating mode, the IOSE bit in SYSCR and the PA1DDR bit.

Operating Mode	Modes 1, 2 (	EXPE = 0), 3	Mode 2 (EXPE = 1)		
PA1DDR	0 1		0	1	
IOSE			_	0	1
Pin Function	PA1 PA1 input pin output pin		PA1 A17 PA1 input pin output pin output pin		
	KIN9 input pin, CIN9 input pin*				

Note: \* This pin can always be used as the KIN9 or CIN9 input pin.

## • PA0/A16/ \( \overline{KIN8} \) / CIN8

Pin functions are switched as shown below according to the combination of operating mode, the IOSE bit in SYSCR and the PA0DDR bit.

Operating Mode	Modes 1, 2 (	EXPE = 0), 3	Mode 2 (EXPE = 1)		
PA0DDR	0 1		0	1	
IOSE	_	_	_	0	1
Pin Function	PA0 input pin	PA0 output pin	PA0 input pin	A16 output pin	PA0 output pin
	KIN8 input pin, CIN8 input pin*				

Note: \* This pin can always be used as the KIN8 or CIN8 input pin.

## 7.11.5 Port A Input Pull-Up MOS

Port A has an on-chip input pull-up MOS function that can be controlled by software. This input pull-up MOS function can be specified as on or off on a bit-by-bit basis.

The input pull-up MOS for pins PA7 to PA4 is always off when IICS is set to 1.

Table 7.7 summarizes the input pull-up MOS states.

**Table 7.7** Input Pull-Up MOS States (Port A)

Mode	Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1, 2, 3	Off	Off	On/Off	On/Off

[Legend]

Off: Input pull-up MOS is always off.

On/Off: On when the pin is in the input state, PADDR = 0, and PAODR = 1; otherwise off.

## 7.12 Port B (Only for H8S/2144B)

Port B is an 8-bit I/O port. Port B pins also have a data bus input/output function. The pin functions depend on the operating mode. Port B has the following registers.

- Port B data direction register (PBDDR)
- Port B output data register (PBODR)
- Port B input data register (PBPIN)

## 7.12.1 Port B Data Direction Register (PBDDR)

PBDDR specifies input or output for the pins of port B on a bit-by-bit basis.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7DDR	0	W	PBDDR has the same address as P7PIN, and if
6	PB6DDR	0	W	read, the port 7 pin states will be returned.
5	PB5DDR	0	W	• Modes 1, 2, and 3 (EXPE = 1)
4	PB4DDR	0	W	When the ABW bit in WSCR is cleared to 0.
3	PB3DDR	0	W	port B pins automatically become data I/O pins
2	PB2DDR	0	W	(D7 to D0), regardless of the input/output
1	PB1DDR	0	W	direction indicated by PBDDR. When the ABW
0	PB0DDR	0	W	<ul> <li>bit is 1, a port B pin becomes an output port if the corresponding PBDDR bit is set to 1, and an input port if the bit is cleared to 0.</li> </ul>
				<ul> <li>Modes 2 and 3 (EXPE = 0)</li> </ul>
				A port B pin becomes an output port if the corresponding PBDDR bit is set to 1, and an input port if the bit is cleared to 0.

## 7.12.2 Port B Output Data Register (PBODR)

PBODR stores output data for port B.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7ODR	0	R/W	PBODR can always be read or written to,
6	PB6ODR	0	R/W	regardless of the contents of PBDDR.
5	PB5ODR	0	R/W	_
4	PB4ODR	0	R/W	_
3	PB3ODR	0	R/W	_
2	PB2ODR	0	R/W	
1	PB1ODR	0	R/W	_
0	PB0ODR	0	R/W	

## 7.12.3 Port B Input Data Register (PBPIN)

PBPIN indicates the port B state.

Bit	Bit Name	Initial Value	R/W	Description
7	PB7PIN	Undefined*	R	Reading PBPIN always returns the pin states.
6	PB6PIN	Undefined*	R	PBPIN has the same address as P8DDR. If a write is performed, data will be written to P8DDR and
5	PB5PIN	Undefined*	R	the port 8 settings will change.
4	PB4PIN	Undefined*	R	_
3	PB3PIN	Undefined*	R	_
2	PB2PIN	Undefined*	R	_
1	PB1PIN	Undefined*	R	<del>-</del> -
0	PB0PIN	Undefined*	R	_

Note: \* The initial value is determined according to the PB7 to PB0 pin states.

#### 7.12.4 Pin Functions

PB7/D7, PB6/D6, PB5/D5, PB4/D4, PB3/D3, PB2/D2, PB1/D1, and PB0/D0
 Pin functions are switched as shown below according to the combination of the operating mode, the PBnDDR bit, and the ABW bit in WSCR.

Operating Mode	Mode 1	and Modes 2, 3	3 (EXPE = 1)	Modes 2, 3	(EXPE = 0)
ABW	0		1	-	_
PBnDDR	_	0	1	0	1
Pin Function	Dn I/O pin	PBn PBn input pin output pin		PBn input pin	PBn output pin

Note: n = 7 to 0

## 7.12.5 Port B Input Pull-Up MOS

Port B has an on-chip input pull-up MOS function that can be controlled by software. This input pull-up MOS function can be specified as on or off on a bit-by-bit basis.

When a pin is specified as an output pin, the input pull-up MOS is always off.

Table 7.8 summarizes the input pull-up MOS states.

Table 7.8 Input Pull-Up MOS States (Port B)

Mode	Reset	Hardware Standby Mode	Software Standby Mode	In Other Operations
1, 2, 3 (EXPE = 1) with ABW in WSCR = 0	Off	Off	Off	Off
1, 2, 3 (EXPE = 1) with ABW in WSCR = 1, or 2, 3 (EXPE = 0)	_		On/Off	On/Off

[Legend]

Off: Input pull-up MOS is always off.

On/Off: On when the pin is in the input state, PBDDR = 0, and PBODR = 1; otherwise off.

## Section 8 14-Bit PWM Timer (PWMX)

This LSI has an on-chip 14-bit pulse-width modulator (PWM) timer with two output channels. It can be connected to an external low-pass filter to operate as a 14-bit D/A converter.

#### 8.1 Features

- Division of pulse into multiple base cycles to reduce ripple
- Two resolution settings
   The resolution can be set equal to one or two system clock cycles.
- Two base cycle settings
   The base cycle can be set equal to T × 64 or T × 256, where T is the resolution.
- Four operating speeds
- Four operation clocks (by combination of two resolution settings and two base cycle settings)

Figure 8.1 shows a block diagram of the PWM (D/A) module.

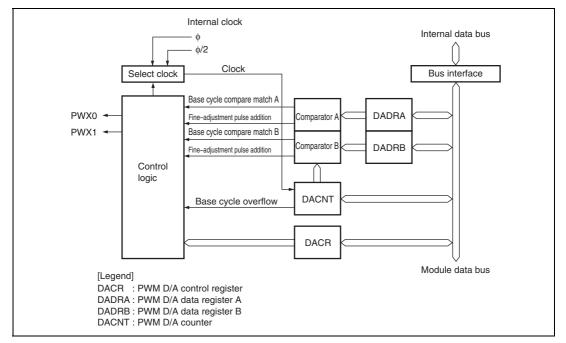

Figure 8.1 PWM (D/A) Block Diagram

## 8.2 Input/Output Pins

Table 8.1 lists the PWM (D/A) module input and output pins.

**Table 8.1** Pin Configuration

Name	Abbreviation	I/O	Function
PWM output pin X0	PWX0	Output	PWM output of PWMX channel A
PWM output pin X1	PWX1	Output	PWM output of PWMX channel B

## 8.3 Register Descriptions

The PWM (D/A) module has the following registers. The PWM (D/A) registers are assigned to the same addresses with other registers. The registers are selected by the IICE bit in the serial timer control register (STCR). For details on STCR, see section 3.2.3, Serial Timer Control Register (STCR).

- PWM (D/A) counter H (DACNTH)
- PWM (D/A) counter L (DACNTL)
- PWM (D/A) data register AH (DADRAH)
- PWM (D/A) data register AL (DADRAL)
- PWM (D/A) data register BH (DADRBH)
- PWM (D/A) data register BL (DADRBL)
- PWM (D/A) control register (DACR)

Note: The same addresses are shared by DADRA and DACR, and by DADRB and DACNT. Switching is performed by the REGS bit in DACNT or DADRB.

## 8.3.1 PWM (D/A) Counters H and L (DACNTH, DACNTL)

DACNT is a 14-bit readable/writable up-counter. The input clock is selected by the clock select bit (CKS) in DACR. DACNT functions as the time base for both PWM (D/A) channels. When a channel operates with 14-bit precision, it uses all DACNT bits. When a channel operates with 12-bit precision, it uses the lower 12 bits and ignores the upper two bits. Since DACNT consists of 16-bit data, DACNT transfers data to the CPU via the temporary register (TEMP). For details, refer to section 8.4, Bus Master Interface.

				[	DACN	ГН			_	-			DAC	NTL			_

				_

# 8.3.2 PWM (D/A) Data Registers A and B (DADRA, DADRB)

DADRA corresponds to PWM (D/A) channel A, and DADRB to PWM (D/A) channel B. Since DADR consists of 16-bit data, DADR transfers data to the CPU via the temporary register (TEMP). For details, refer to section 8.4, Bus Master Interface.

#### DADRA

Bit	Bit Name	Initial Value	R/W	Description
15	DA13	1	R/W	D/A Data 13 to 0
14	DA12	1	R/W	These bits set a digital value to be converted to an

Bit	Bit Name	Initial Value	R/W	Description
0	CKS	0	R/W	Clock Select
				Selects the PWM (D/A) resolution. If the system clock (\$\phi\$) frequency is 10 MHz, resolutions of 100 ns and 200 ns, can be selected.
				0: Operates at resolution (T) = system clock cycle time $(t_{cyc})$
				1: Operates at resolution (T) = system clock cycle time $(t_{cyc}) \times 2$

#### **8.4** Bus Master Interface

DACNT, DADRA, and DADRB are 16-bit registers. The data bus linking the bus master and the on-chip peripheral modules, however, is only 8 bits wide. When the bus master accesses these registers, it therefore uses an 8-bit temporary register (TEMP).

These registers are written to and read from as follows.

**Write:** When the upper byte is written to, the upper-byte write data is stored in TEMP. Next, when the lower byte is written to, the lower-byte write data and TEMP value are combined, and the combined 16-bit value is written in the register.

**Read:** When the upper byte is read from, the upper-byte value is transferred to the CPU and the lower-byte value is transferred to TEMP. Next, when the lower byte is read from, the lower-byte value in TEMP is transferred to the CPU.

These registers should always be accessed 16 bits at a time with a MOV instruction, and the upper byte should always be accessed before the lower byte. Correct data will not be transferred if only the upper byte or only the lower byte is accessed. Also note that a bit manipulation instruction cannot be used to access these registers.

#### **Example 1:** Write to DACNT

MOV.W RO, @DACNT; Write RO contents to DACNT

### Example 2: Read DADRA

MOV.W @DADRA, RO ; Copy contents of DADRA to RO

Table 8.2 Read and Write Access Methods for 16-Bit Registers

		Read		Write	
Register Name	Word	Byte	Word	Byte	
DADRA and DADRB	Yes	Yes	Yes	×	
DACNT	Yes	×	Yes	×	

[Legend]

Yes: Permitted type of access. Word access includes successive byte accesses to the upper byte (first) and lower byte (second).

x: This type of access may give incorrect results.

# 8.5 Operation

A PWM waveform like the one shown in figure 8.2 is output from the PWMX pin. The value in DADR corresponds to the total width  $(T_L)$  of the low (0) pulses output in one conversion cycle (256 pulses when CFS = 0, 64 pulses when CFS = 1). When OS = 0, this waveform is directly output. When OS = 1, the output waveform is inverted, and the DADR value corresponds to the total width  $(T_H)$  of the high (1) output pulses. Figures 8.3 and 8.4 show the types of waveform output available.

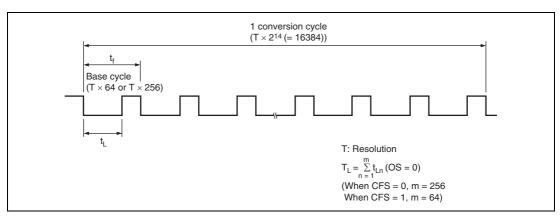

Figure 8.2 PWM D/A Operation

Table 8.3 summarizes the relationships between the CKS, CFS, and OS bit settings and the resolution, base cycle, and conversion cycle. The PWM output remains fixed unless DADR contains at least a certain minimum value.

Table 8.3 Settings and Operation (Examples when  $\phi = 10 \text{ MHz}$ )

							Fixed	d D	ADF	R Bi	ts	
			Base				Pre-		Bit	Dat	а	_

					2.	(Data value) × T (DADR = H'0103 to H'FFFF)	10	0	0	0	0	204.8
<del></del>							·" DAE				٠.	

Note: \* This column indicates the conversion cycle when specific DADR bits are fixed.

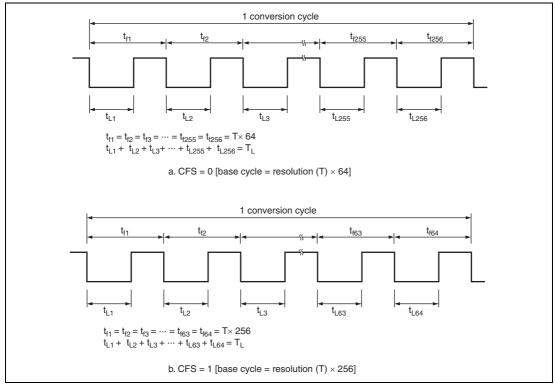

Figure 8.3 Output Waveform (OS = 0, DADR corresponds to  $T_L$ )

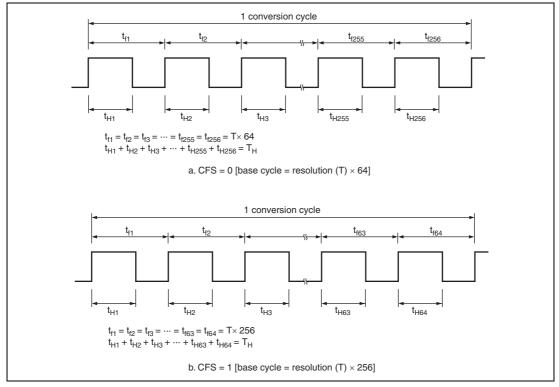

Figure 8.4 Output Waveform (OS = 1, DADR corresponds to  $T_{\mu}$ )

An example of setting CFS to 1 (basic cycle = resolution (T)  $\times$  256) and OS to 1 (PWMX inverted output) is shown as an additional pulse. When CFS is set to 1, the duty ratio of the basic pulse is determined by the upper eight bits (DA13 to DA6) in DADR, and the position of the additional pulse is determined by the following six bits (DA5 to DA0) as shown in figure 8.5.

Table 8.4 shows the position of the additional pulse.

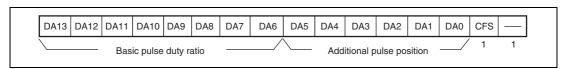

Figure 8.5 D/A Data Register Configuration when CFS = 1

Here, the case of DADR = H'0207 (B'0000 0010 0000 0111) is considered. Figure 8.6 shows an output waveform. Because CFS = 1 and the value of upper eight bits is B'0000 0010, the duty ratio of the basic pulse is  $2/256 \times (T)$  of high width.

Since the value of the following six bits is B'0000 01, the additional pulse is output at the position of basic pulse No. 63 as shown in table 8.4. Only  $1/256 \times (T)$  of the additional pulse is added to the basic pulse.

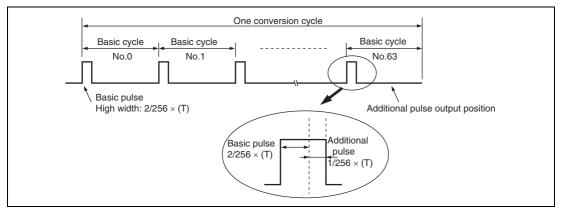

Figure 8.6 Output Waveform when DADR = H'0207 (OS = 1)

Note that the case of CFS = 0 (basic cycle = resolution  $(T) \times 64$ ) is similar other than the duty ratio of the basic pulse is determined by the upper six bits, and the position of the additional pulse is determined by the following eight bits.

Table 8.4 Position of Pulse to be Added to Basic Pulse (CFS = 1)

# 8.6 Usage Note

# 8.6.1 Module Stop Mode Setting

PWMX operation can be enabled or disabled using the module stop control register. The initial setting is for PWMX operation to be halted. Register access is enabled by canceling the module stop mode. For details, refer to section 18, Power-Down Modes.

# Section 9 16-Bit Free-Running Timer (FRT)

This LSI has an on-chip 16-bit free-running timer (FRT). The FRT operates on the basis of the 16-bit free-running counter (FRC), and outputs two independent waveforms, and measures the input pulse width and external clock periods.

#### 9.1 Features

- Selection of four clock sources
  - One of the three internal clocks ( $\phi/2$ ,  $\phi/8$ , or  $\phi/32$ ), or an external clock input can be selected (enabling use as an external event counter).
- Two independent comparators
  - Two independent waveforms can be output.
- Four independent input capture channels
  - The rising or falling edge can be selected.
  - Buffer modes can be specified.
- Counter clearing
  - The free-running counters can be cleared on compare-match A.
- Seven independent interrupts
  - Two compare-match interrupts, four input capture interrupts, and one overflow interrupt can be requested independently.
- Special functions provided by automatic addition function
  - The contents of OCRAR and OCRAF can be added to the contents of OCRA automatically, enabling a periodic waveform to be generated without software intervention. The contents of ICRD can be added automatically to the contents of OCRDM  $\times$  2, enabling input capture operations in this interval to be restricted.

Figure 9.1 shows a block diagram of the FRT.

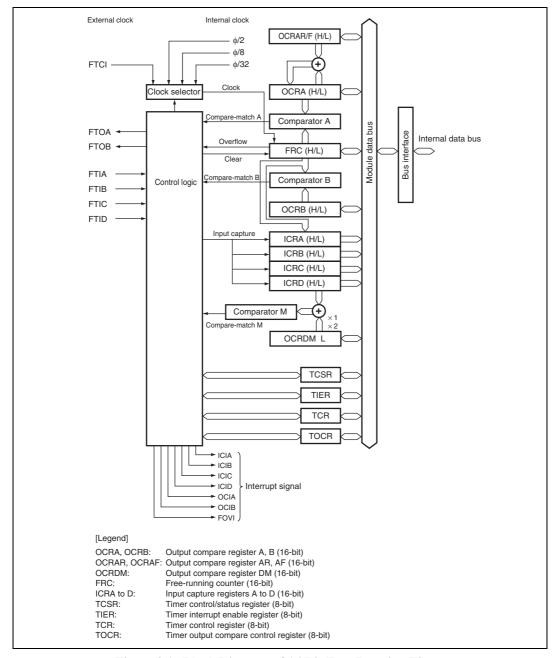

Figure 9.1 Block Diagram of 16-Bit Free-Running Timer

# 9.2 Input/Output Pins

Table 9.1 lists the FRT input and output pins.

**Table 9.1** Pin Configuration

Name	Abbreviation	I/O	Function
Counter clock input pin	FTCI	Input	FRC counter clock input
Output compare A output pin	FTOA	Output	Output compare A output
Output compare B output pin	FTOB	Output	Output compare B output
Input capture A input pin	FTIA	Input	Input capture A input
Input capture B input pin	FTIB	Input	Input capture B input
Input capture C input pin	FTIC	Input	Input capture C input
Input capture D input pin	FTID	Input	Input capture D input

# 9.3 Register Descriptions

The FRT has the following registers.

- Free-running counter (FRC)
- Output compare register A (OCRA)
- Output compare register B (OCRB)
- Input capture register A (ICRA)
- Input capture register B (ICRB)
- Input capture register C (ICRC)
- Input capture register D (ICRD)
- Output compare register AR (OCRAR)
- Output compare register AF (OCRAF)
- Output compare register DM (OCRDM)
- Timer interrupt enable register (TIER)
- Timer control/status register (TCSR)
- Timer control register (TCR)
- Timer output compare control register (TOCR)

Note: OCRA and OCRB share the same address. Register selection is controlled by the OCRS bit in TOCR. ICRA, ICRB, and ICRC share the same addresses with OCRAR, OCRAF, and OCRDM. Register selection is controlled by the ICRS bit in TOCR.

#### 9.3.1 Free-Running Counter (FRC)

FRC is a 16-bit readable/writable up-counter. The clock source is selected by bits CKS1 and CKS0 in TCR. FRC can be cleared by compare-match A. When FRC overflows from H'FFFF to H'0000, the overflow flag bit (OVF) in TCSR is set to 1. FRC should always be accessed in 16-bit units; cannot be accessed in 8-bit units. FRC is initialized to H'0000.

#### 9.3.2 Output Compare Registers A and B (OCRA, OCRB)

The FRT has two output compare registers, OCRA and OCRB, each of which is a 16-bit readable/writable register whose contents are continually compared with the value in FRC. When a match is detected (compare-match), the corresponding output compare flag (OCFA or OCFB) is set to 1 in TCSR. If the OEA or OEB bit in TOCR is set to 1, when the OCR and FRC values match, the output level selected by the OLVLA or OLVLB bit in TOCR is output at the output compare output pin (FTOA or FTOB). Following a reset, the FTOA and FTOB output levels are 0 until the first compare-match. OCR should always be accessed in 16-bit units; cannot be accessed in 8-bit units. OCR is initialized to H'FFFE.

#### 9.3.3 Input Capture Registers A to D (ICRA to ICRD)

The FRT has four input capture registers, ICRA to ICRD, each of which is a 16-bit read-only register. When the rising or falling edge of the signal at an input capture input pin (FTIA to FTID) is detected, the current FRC value is transferred to the corresponding input capture register (ICRA to ICRD). At the same time, the corresponding input capture flag (ICFA to ICFD) in TCSR is set to 1. The FRC contents are transferred to ICR regardless of the value of ICF. The input capture edge is selected by the input edge select bits (IEDGA to IEDGD) in TCR.

ICRC and ICRD can be used as ICRA and ICRB buffer registers, respectively, by means of buffer enable bits A and B (BUFEA and BUFEB) in TCR. For example, if an input capture occurs when ICRC is specified as the ICRA buffer register, the FRC contents are transferred to ICRA, and then transferred to the buffer register ICRC.

To ensure input capture, the input capture pulse width should be at least 1.5 system clocks ( $\phi$ ) for a single edge. When triggering is enabled on both edges, the input capture pulse width should be at least 2.5 system clocks ( $\phi$ ).

ICRA to ICRD should always be accessed in 16-bit units; cannot be accessed in 8-bit units. ICR is initialized to H'0000.

#### 9.3.4 Output Compare Registers AR and AF (OCRAR, OCRAF)

OCRAR and OCRAF are 16-bit readable/writable registers. When the OCRAMS bit in TOCR is set to 1, the operation of OCRA is changed to include the use of OCRAR and OCRAF. The contents of OCRAR and OCRAF are automatically added alternately to OCRA, and the result is written to OCRA. The write operation is performed on the occurrence of compare-match A. In the 1st compare-match A after setting the OCRAMS bit to 1, OCRAF is added. The operation due to compare-match A varies according to whether the compare-match follows addition of OCRAR or OCRAF. The value of the OLVLA bit in TOCR is ignored, and 1 is output on a compare-match A following addition of OCRAF, while 0 is output on a compare-match A following addition of OCRAR.

When using the OCRA automatic addition function, do not select internal clock  $\phi/2$  as the FRC input clock together with a set value of H'0001 or less for OCRAR (or OCRAF).

OCRAR and OCRAF should always be accessed in 16-bit units; cannot be accessed in 8-bit units. OCRAR and OCRAF are initialized to H'FFFF.

### 9.3.5 Output Compare Register DM (OCRDM)

OCRDM is a 16-bit readable/writable register in which the upper 8 bits are fixed at H'00. When the ICRDMS bit in TOCR is set to 1 and the contents of OCRDM are other than H'0000, the operation of ICRD is changed to include the use of OCRDM. The point at which input capture D occurs is taken as the start of a mask interval. Next, twice the contents of OCRDM is added to the contents of ICRD, and the result is compared with the FRC value. The point at which the values match is taken as the end of the mask interval. New input capture D events are disabled during the mask interval. A mask interval is not generated when the contents of OCRDM are H'0000 while the ICRDMS bit is set to 1.

OCRDM should always be accessed in 16-bit units; cannot be accessed in 8-bit units. OCRDM is initialized to H'0000.

# 9.3.6 Timer Interrupt Enable Register (TIER)

TIER enables and disables interrupt requests.

Bit	Bit Name	Initial Value	R/W	Description
7	ICIAE	0	R/W	Input Capture Interrupt A Enable
				Selects whether to enable input capture interrupt A request (ICIA) when input capture flag A (ICFA) in TCSR is set to 1.
				0: ICIA requested by ICFA is disabled
				1: ICIA requested by ICFA is enabled
6	ICIBE	0	R/W	Input Capture Interrupt B Enable
				Selects whether to enable input capture interrupt B request (ICIB) when input capture flag B (ICFB) in TCSR is set to 1.
				0: ICIB requested by ICFB is disabled
				1: ICIB requested by ICFB is enabled
5	ICICE	0	R/W	Input Capture Interrupt C Enable
				Selects whether to enable input capture interrupt C request (ICIC) when input capture flag C (ICFC) in TCSR is set to 1.
				0: ICIC requested by ICFC is disabled
				1: ICIC requested by ICFC is enabled
4	ICIDE	0	R/W	Input Capture Interrupt D Enable
				Selects whether to enable input capture interrupt D request (ICID) when input capture flag D (ICFD) in TCSR is set to 1.
				0: ICID requested by ICFD is disabled
				1: ICID requested by ICFD is enabled
3	OCIAE	0	R/W	Output Compare Interrupt A Enable
				Selects whether to enable output compare interrupt A request (OCIA) when output compare flag A (OCFA) in TCSR is set to 1.
				0: OCIA requested by OCFA is disabled
				1: OCIA requested by OCFA is enabled

Bit	Bit Name	Initial Value	R/W	Description	
2	OCIBE	0	R/W	Output Compare Interrupt B Enable	
				Selects whether to enable output compare interrupt B request (OCIB) when output compare flag B (OCFB) in TCSR is set to 1.	
				0: OCIB requested by OCFB is disabled	
				1: OCIB requested by OCFB is enabled	
1	OVIE	0	R/W	Timer Overflow Interrupt Enable	
				Selects whether to enable a free-running timer overflow request interrupt (FOVI) when the timer overflow flag (OVF) in TCSR is set to 1.	
				0: FOVI requested by OVF is disabled	
				1: FOVI requested by OVF is enabled	
0	_	0	R	Reserved	
				This bit is always read as 1 and cannot be modified.	

# 9.3.7 Timer Control/Status Register (TCSR)

TCSR is used for counter clear selection and control of interrupt request signals.

Bit	Bit Name	Initial Value	R/W	Description	
7	ICFA	0	R/(W)*	Input Capture Flag A	
			This status flag indicates that the FRC value he transferred to ICRA by means of an input capt signal. When BUFEA = 1, ICFA indicates that ICRA value has been moved into ICRC and the FRC value has been transferred to ICRA. Only be written to this bit to clear the flag.		
				[Setting condition]	
				When an input capture signal causes the FRC value to be transferred to ICRA	
				[Clearing condition]	
				Read ICFA when ICFA = 1, then write 0 to ICFA	

Bit	Bit Name	Initial Value	R/W	Description	
6	ICFB	0	R/(W)*	Input Capture Flag B	
				This status flag indicates that the FRC value has been transferred to ICRB by means of an input capture signal. When BUFEB = 1, ICFB indicates that the old ICRB value has been moved into ICRD and the new FRC value has been transferred to ICRB. Only 0 can be written to this bit to clear the flag.	
				[Setting condition]	
				When an input capture signal causes the FRC value to be transferred to ICRB	
				[Clearing condition]	
				Read ICFB when ICFB = 1, then write 0 to ICFB	
5	ICFC	0	R/(W)*	Input Capture Flag C	
				This status flag indicates that the FRC value has been transferred to ICRC by means of an input capture signal. When BUFEA = 1, on occurrence of an input capture signal specified by the IEDGC bit at the FTIC input pin, ICFC is set but data is not transferred to ICRC. In buffer operation, ICFC can be used as an external interrupt signal by setting the ICICE bit to 1. Only 0 can be written to this bit to clear the flag.	
				[Setting condition]	
				When an input capture signal is received	
				[Clearing condition]	
				Read ICFC when ICFC = 1, then write 0 to ICFC	
4	ICFD	0	R/(W)*	Input Capture Flag D	
				This status flag indicates that the FRC value has been transferred to ICRD by means of an input capture signal. When BUFEB = 1, on occurrence of an input capture signal specified by the IEDGD bit at the FTID input pin, ICFD is set but data is not transferred to ICRD. In buffer operation, ICFD can be used as an external interrupt signal by setting the ICIDE bit to 1. Only 0 can be written to this bit to clear the flag.	
				[Setting condition]	
				When an input capture signal is received	
				[Clearing condition]	
				Read ICFD when ICFD = 1, then write 0 to ICFD	

Bit	Bit Name	Initial Value	R/W	Description	
3	OCFA	0	R/(W)*	Output Compare Flag A	
				This status flag indicates that the FRC value matches the OCRA value. Only 0 can be written to this bit to clear the flag.	
				[Setting condition]	
				When FRC = OCRA	
				[Clearing condition]	
				Read OCFA when OCFA = 1, then write 0 to OCFA	
2	OCFB	0	R/(W)*	Output Compare Flag B	
				This status flag indicates that the FRC value matches the OCRB value. Only 0 can be written to this bit to clear the flag.	
				[Setting condition]	
				When FRC = OCRB	
				[Clearing condition]	
				Read OCFB when OCFB = 1, then write 0 to OCFB	
1	OVF	0	R/(W)*	Timer Overflow	
				This status flag indicates that the FRC has overflowed. Only 0 can be written to this bit to clear the flag.	
				[Setting condition]	
				When FRC overflows (changes from H'FFFF to H'0000)	
				[Clearing condition]	
				Read OVF when OVF = 1, then write 0 to OVF	
0	CCLRA	0	R/W	Counter Clear A	
				This bit selects whether the FRC is to be cleared at compare-match A (when the FRC and OCRA values match).	
				0: FRC clearing is disabled	
				1: FRC is cleared at compare-match A	

Note \* Only 0 can be written to clear the flag.

# 9.3.8 Timer Control Register (TCR)

TCR selects the rising or falling edge of the input capture signals, enables the input capture buffer mode, and selects the FRC clock source.

				11: External clock source (counting at FTCI rising edge)	

# 9.3.9 Timer Output Compare Control Register (TOCR)

TOCR enables output from the output compare pins, selects the output levels, switches access between output compare registers A and B, controls the ICRD and OCRA operating modes, and switches access to input capture registers A, B, and C.

Bit	Bit Name	Initial Value	R/W	Description
7	ICRDMS	0	R/W	Input Capture D Mode Select
				Specifies whether ICRD is used in the normal operating mode or in the operating mode using OCRDM.
				0: The normal operating mode is specified for ICRD
				1: The operating mode using OCRDM is specified for ICRD
6	OCRAMS	0	R/W	Output Compare A Mode Select
				Specifies whether OCRA is used in the normal operating mode or in the operating mode using OCRAR and OCRAF.
				0: The normal operating mode is specified for OCRA
				1: The operating mode using OCRAR and OCRAF is specified for OCRA
5	ICRS	0	R/W	Input Capture Register Select
				The same addresses are shared by ICRA and OCRAR, by ICRB and OCRAF, and by ICRC and OCRDM. The ICRS bit determines which registers are selected when the shared addresses are read from or written to. The operation of ICRA, ICRB, and ICRC is not affected.
				0: ICRA, ICRB, and ICRC are selected
				1: OCRAR, OCRAF, and OCRDM are selected

Bit	Bit Name	Initial Value	R/W	Description	
4	OCRS	0	R/W	Output Compare Register Select	
				OCRA and OCRB share the same address. When this address is accessed, the OCRS bit selects which register is accessed. The operation of OCRA or OCRB is not affected.	
				0: OCRA is selected	
				1: OCRB is selected	
3	OEA	0	R/W	Output Enable A	
				Enables or disables output of the output compare A output pin (FTOA).	
				0: Output compare A output is disabled	
				1: Output compare A output is enabled	
2	OEB	0	R/W	Output Enable B	
				Enables or disables output of the output compare B output pin (FTOB).	
				0: Output compare B output is disabled	
				1: Output compare B output is enabled	
1	OLVLA	0	R/W	Output Level A	
				Selects the level to be output at the output compare output pin (FTOA) in response to compare-match A (signal indicating a match between the FRC and OCF values). When the OCRAMS bit is 1, this bit is ignore	
				0: 0 is output at compare-match A	
				1: 1 is output at compare-match A	
0	OLVLB	0	R/W	Output Level B	
				Selects the level to be output at the output compare B output pin (FTOB) in response to compare-match B (signal indicating a match between the FRC and OCRB values).	
				0: 0 is output at compare-match B	
				1: 1 is output at compare-match B	

# 9.4 Operation

### 9.4.1 Pulse Output

Figure 9.2 shows an example of 50%-duty pulses output with an arbitrary phase difference. When a compare match occurs while the CCLRA bit in TCSR is set to 1, the OLVLA and OLVLB bits are inverted by software.

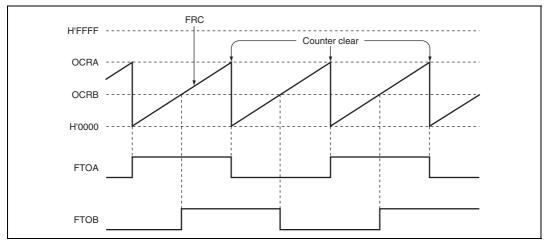

Figure 9.2 Example of Pulse Output

# 9.5 Operation Timing

# 9.5.1 FRC Increment Timing

Figure 9.3 shows the FRC increment timing with an internal clock source. Figure 9.4 shows the increment timing with an external clock source. The pulse width of the external clock signal must be at least 1.5 system clocks ( $\phi$ ). The counter will not increment correctly if the pulse width is shorter than 1.5 system clocks ( $\phi$ ).

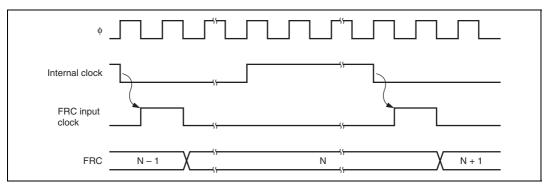

Figure 9.3 Increment Timing with Internal Clock Source

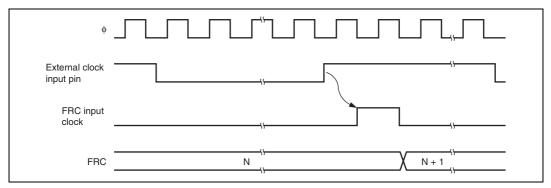

Figure 9.4 Increment Timing with External Clock Source

### 9.5.2 Output Compare Output Timing

A compare-match signal occurs at the last state when the FRC and OCR values match (at the timing when the FRC updates the counter value). When a compare-match signal occurs, the level selected by the OLVL bit in TOCR is output at the output compare pin (FTOA or FTOB). Figure 9.5 shows the timing of this operation for compare-match A.

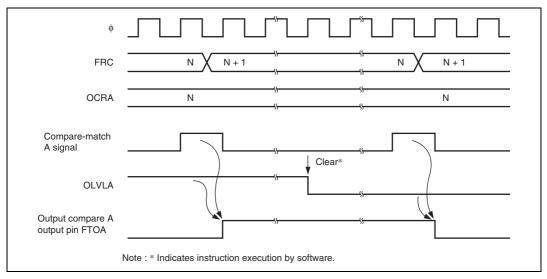

Figure 9.5 Timing of Output Compare A Output

# 9.5.3 FRC Clear Timing

FRC can be cleared when compare-match A occurs. Figure 9.6 shows the timing of this operation.

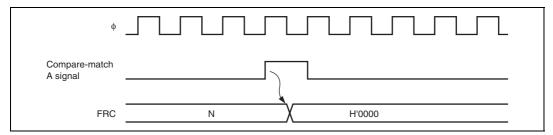

Figure 9.6 Clearing of FRC by Compare-Match A Signal

### 9.5.4 Input Capture Input Timing

The rising or falling edge can be selected for the input capture input timing by the IEDGA to IEDGD bits in TCR. Figure 9.7 shows the usual input capture timing when the rising edge is selected.

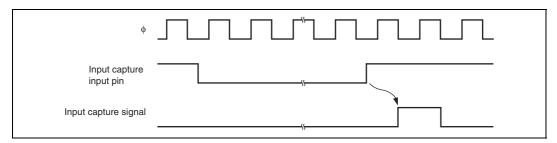

Figure 9.7 Input Capture Input Signal Timing (Usual Case)

If ICRA to ICRAD are read when the corresponding input capture signal arrives, the internal input capture signal is delayed by one system clock  $(\phi)$ . Figure 9.8 shows the timing for this case.

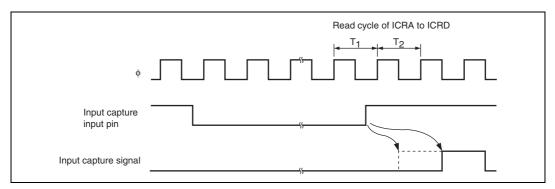

Figure 9.8 Input Capture Input Signal Timing (When ICRA to ICRD are Read)

#### 9.5.5 Buffered Input Capture Input Timing

ICRC and ICRD can operate as buffers for ICRA and ICRB, respectively. Figure 9.9 shows how input capture operates when ICRC is used as ICRA's buffer register (BUFEA = 1) and IEDGA and IEDGC are set to different values (IEDGA = 0 and IEDGC = 1, or IEDGA = 1 and IEDGC = 0), so that input capture is performed on both the rising and falling edges of FTIA.

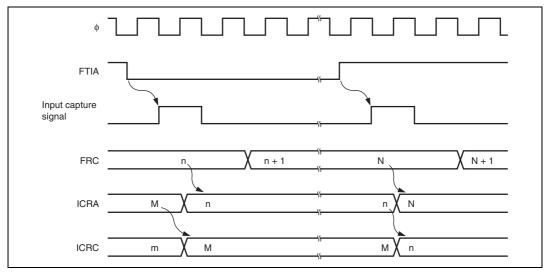

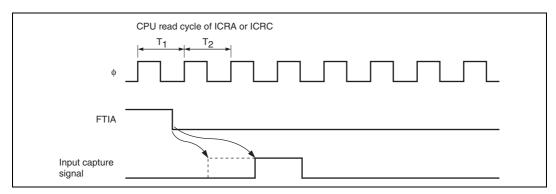

Figure 9.9 Buffered Input Capture Timing

Even when ICRC or ICRD is used as a buffer register, its input capture flag is set by the selected transition of its input capture signal. For example, if ICRC is used to buffer ICRA, when the edge transition selected by the IEDGC bit occurs on the FTIC input capture line, ICFC will be set, and if the ICICE bit is set at this time, an interrupt will be requested. The FRC value will not be transferred to ICRC, however. In buffered input capture, if either set of two registers to which data will be transferred (ICRA and ICRC, or ICRB and ICRD) is being read when the input capture input signal arrives, input capture is delayed by one system clock  $(\phi)$ . Figure 9.10 shows the timing when BUFEA = 1.

**Figure 9.10 Buffered Input Capture Timing (BUFEA = 1)** 

# 9.5.6 Timing of Input Capture Flag (ICF) Setting

The input capture flag, ICFA, ICFB, ICFC, or ICFD, is set to 1 by the input capture signal. The FRC value is simultaneously transferred to the corresponding input capture register (ICRA, ICRB, ICRC, or ICRD). Figure 9.11 shows the timing of setting the ICFA to ICFD flag.

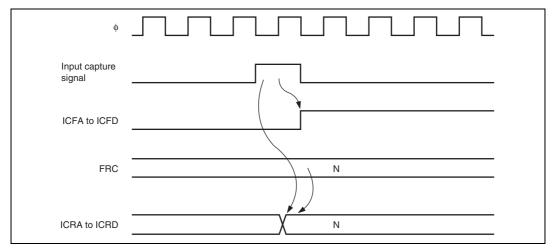

Figure 9.11 Timing of Input Capture Flag (ICFA, ICFB, ICFC, or ICFD) Setting

### 9.5.7 Timing of Output Compare Flag (OCF) setting

The output compare flag, OCFA or OCFB, is set to 1 by a compare-match signal generated when the FRC value matches the OCRA or OCRB value. This compare-match signal is generated at the last state in which the two values match, just before FRC increments to a new value. When the FRC and OCRA or OCRB value match, the compare-match signal is not generated until the next cycle of the clock source. Figure 9.12 shows the timing of setting the OCFA or OCFB flag.

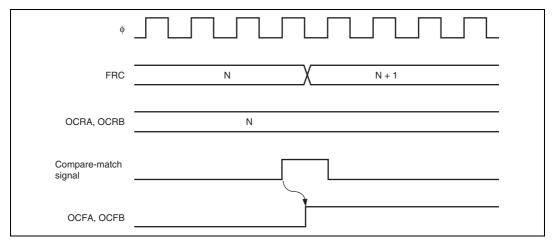

Figure 9.12 Timing of Output Compare Flag (OCFA or OCFB) Setting

# 9.5.8 Timing of FRC Overflow Flag Setting

The FRC overflow flag (OVF) is set to 1 when FRC overflows (changes from H'FFFF to H'0000). Figure 9.13 shows the timing of setting the OVF flag.

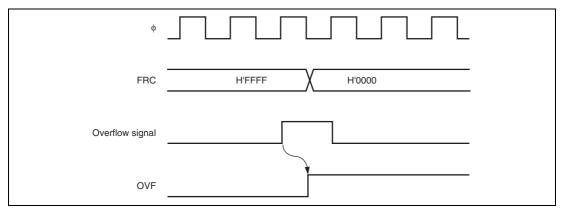

Figure 9.13 Timing of Overflow Flag (OVF) Setting

# 9.5.9 Automatic Addition Timing

When the OCRAMS bit in TOCR is set to 1, the contents of OCRAR and OCRAF are automatically added to OCRA alternately, and when an OCRA compare-match occurs a write to OCRA is performed. Figure 9.14 shows the OCRA write timing.

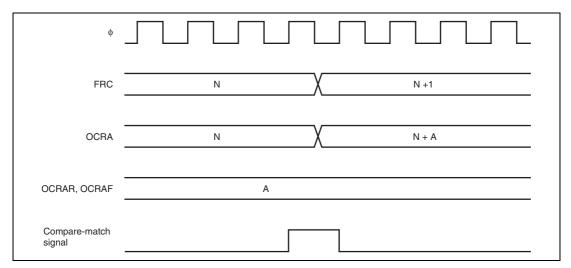

Figure 9.14 OCRA Automatic Addition Timing

### 9.5.10 Mask Signal Generation Timing

When the ICRDMS bit in TOCR is set to 1 and the contents of OCRDM are other than H'0000, a signal that masks the ICRD input capture signal is generated. The mask signal is set by the input capture signal. The mask signal is cleared by the sum of the ICRD contents and twice the OCRDM contents, and an FRC compare-match. Figure 9.15 shows the timing of setting the mask signal. Figure 9.16 shows the timing of clearing the mask signal.

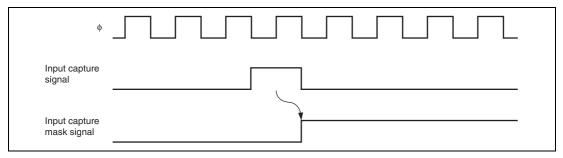

Figure 9.15 Timing of Input Capture Mask Signal Setting

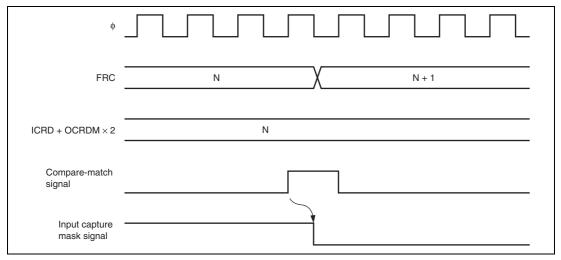

Figure 9.16 Timing of Input Capture Mask Signal Clearing

# 9.6 Interrupt Sources

The free-running timer can request seven interrupts: ICIA to ICID, OCIA, OCIB, and FOVI. Each interrupt can be enabled or disabled by an enable bit in TIER. Independent signals are sent to the interrupt controller for each interrupt. Table 9.2 lists the sources and priorities of these interrupts.

**Table 9.2** FRT Interrupt Sources

Interrupt	Interrupt Source	Interrupt Flag	Priority
ICIA	Input capture of ICRA	ICFA	High
ICIB	Input capture of ICRB	ICFB	_
ICIC	Input capture of ICRC	ICFC	_
ICID	Input capture of ICRD	ICFD	_
OCIA	Compare match of OCRA	OCFA	_
OCIB	Compare match of OCRB	OCFB	_
FOVI	Overflow of FRC	OVF	Low

# 9.7 Usage Notes

#### 9.7.1 Conflict between FRC Write and Clear

If an internal counter clear signal is generated during the state after an FRC write cycle, the clear signal takes priority and the write is not performed. Figure 9.17 shows the timing for this type of conflict.

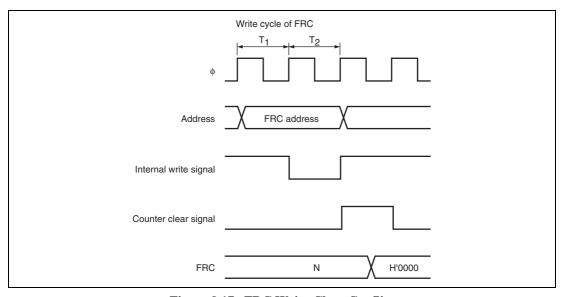

Figure 9.17 FRC Write-Clear Conflict

#### 9.7.2 Conflict between FRC Write and Increment

If an FRC increment pulse is generated during the state after an FRC write cycle, the write takes priority and FRC is not incremented. Figure 9.18 shows the timing for this type of conflict.

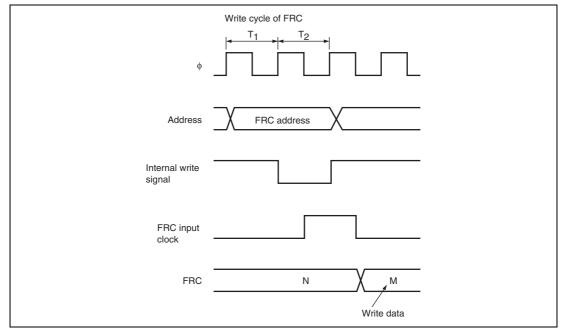

Figure 9.18 FRC Write-Increment Conflict

### 9.7.3 Conflict between OCR Write and Compare-Match

If a compare-match occurs during the state after an OCRA or OCRB write cycle, the write takes priority and the compare-match signal is disabled. Figure 9.19 shows the timing for this type of conflict.

If automatic addition of OCRAR and OCRAF to OCRA is selected, and a compare-match occurs in the cycle following the OCRA, OCRAR, and OCRAF write cycle, the OCRA, OCRAR and OCRAF write takes priority and the compare-match signal is disabled. Consequently, the result of the automatic addition is not written to OCRA. Figure 9.20 shows the timing for this type of conflict.

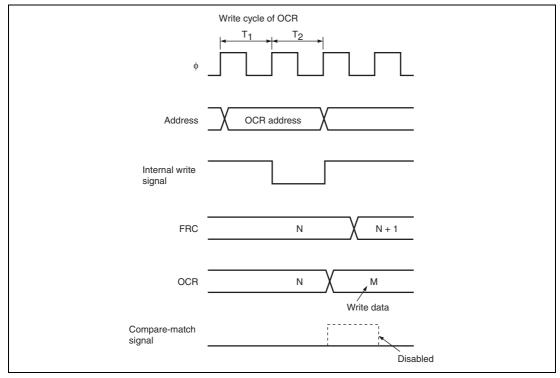

Figure 9.19 Conflict between OCR Write and Compare-Match (When Automatic Addition Function is Not Used)

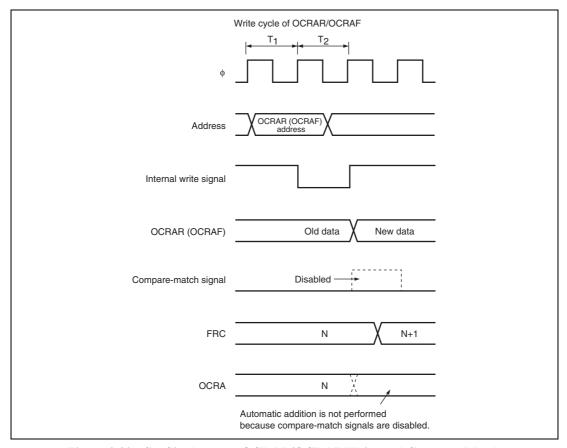

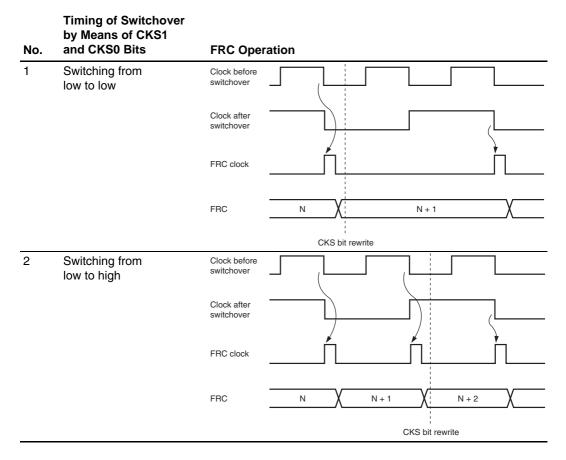

Figure 9.20 Conflict between OCRAR/OCRAF Write and Compare-Match (When Automatic Addition Function is Used)

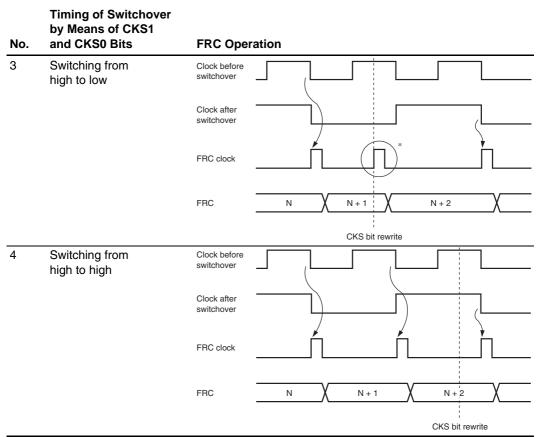

#### 9.7.4 Switching of Internal Clock and FRC Operation

When the internal clock is changed, the changeover may cause FRC to increment. This depends on the time at which the clock is switched (bits CKS1 and CKS0 are rewritten), as shown in table 9.3.

When an internal clock is used, the FRC clock is generated on detection of the falling edge of the internal clock scaled from the system clock ( $\phi$ ). If the clock is changed when the old source is high and the new source is low, as in case no. 3 in table 9.3, the changeover is regarded as a falling edge that triggers the FRC clock, and FRC is incremented. Switching between an internal clock and external clock can also cause FRC to increment.

Table 9.3 Switching of Internal Clock and FRC Operation

Note: \* Generated on the assumption that the switchover is a falling edge; FRC is incremented.

## 9.7.5 Module Stop Mode Setting

FRT operation can be enabled or disabled using the module stop control register. The initial setting is for FRT operation to be halted. Register access is enabled by canceling the module stop mode. For details, refer to section 18, Power-Down Modes.

# Section 10 8-Bit Timer (TMR)

This LSI has three channels of on-chip 8-bit timer modules (TMR\_0, TMR\_1, and TMR\_Y) made up of 8-bit counters. The 8-bit timer module can count external events, and can also be used as a multifunction timer in a variety of applications, such as generation of counter reset, interrupt requests, and pulse output with an arbitrary duty cycle using a compare-match signal with two registers.

#### 10.1 Features

- Selection of clock sources
  - TMR\_0, TMR\_1: The counter input clock can be selected from six internal clocks and an external clock
  - TMR\_Y: The counter input clock can be selected from three internal clocks and an external clock
- Selection of three ways to clear the counters
  - The counters can be cleared on compare-match A or compare-match B, or by an external reset signal.
- Timer output controlled by two compare-match signals
  - The timer output signal in each channel is controlled by two independent compare-match signals, enabling the timer to be used for various applications, such as the generation of pulse output or PWM output with an arbitrary duty cycle. (The TMR\_Y does not have a timer output pin.)
- Cascading of TMR\_0 and TMR\_1
  - Operation as a 16-bit timer can be performed using TMR\_0 as the upper half and TMR\_1 as the lower half (16-bit count mode).
  - TMR\_1 can be used to count TMR\_0 compare-match occurrences (compare-match count mode).
- Multiple interrupt sources for each channel
   TMR\_0, TMR\_1, and TMR\_Y: Three types of interrupts: Compare-match A, compare-match B, and overflow

Figures 10.1 and 10.2 show block diagrams of the 8-bit timer module.

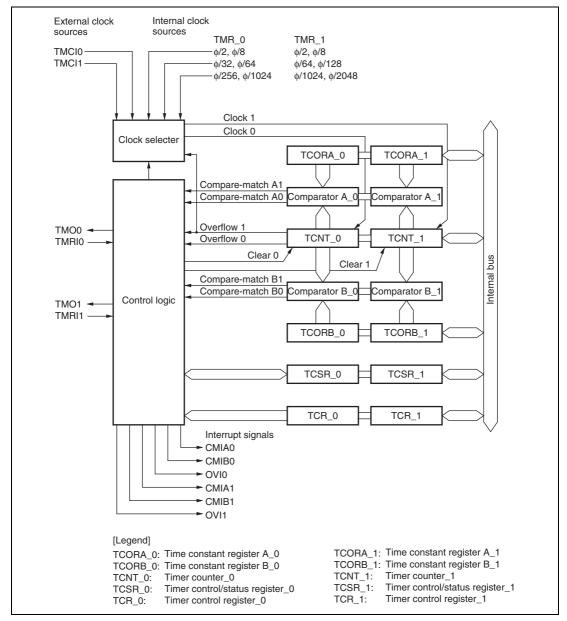

Figure 10.1 Block Diagram of 8-Bit Timers (TMR 0 and TMR 1)

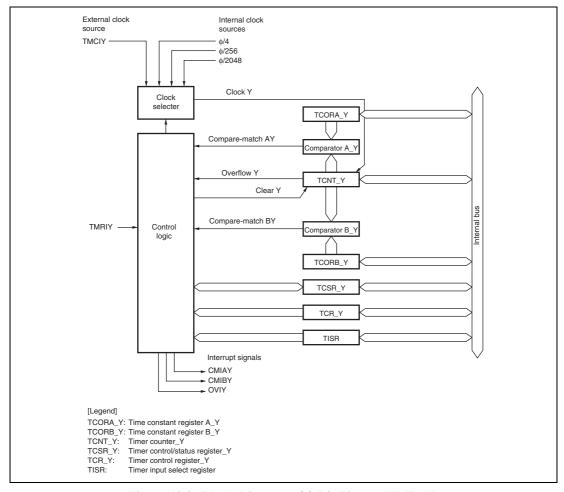

Figure 10.2 Block Diagram of 8-Bit Timers (TMR\_Y)

### 10.2 Input/Output Pins

Table 10.1 summarizes the input and output pins of the TMR.

**Table 10.1 Pin Configuration** 

Channel	Name	Symbol	I/O	Function	
TMR_0	Timer output	TMO0	Output	Output controlled by compare-match	
	Timer clock input	TMCI0	Input	External clock input for the counter	
	Timer reset input	TMRI0	Input	External reset input for the counter	
TMR_1	Timer output	TMO1	Output	Output controlled by compare-match	
	Timer clock input	TMCI1	Input	External clock input for the counter	
	Timer reset input	TMRI1	Input	External reset input for the counter	
TMR_Y	Timer clock/reset input	TMIY (TMCIY/TMRIY)	Input	External clock input for the counter/ external reset input for the counter	

### 10.3 Register Descriptions

The TMR has the following registers. For details on the serial timer control register, refer to section 3.2.3, Serial Timer Control Register (STCR).

- Timer counter (TCNT)
- Time constant register A (TCORA)
- Time constant register B (TCORB)
- Timer control register (TCR)
- Timer control/status register (TCSR)
- Timer input select register (TISR)\*

Note: \* TISR is only for the TMR\_Y.

### **10.3.1** Timer Counter (TCNT)

Each TCNT is an 8-bit readable/writable up-counter. TCNT\_0 and TCNT\_1 comprise a single 16-bit register, so they can be accessed together by word access. The clock source is selected by the CKS2 to CKS0 bits in TCR. TCNT can be cleared by an external reset input signal, comparematch A signal or compare-match B signal. The method of clearing can be selected by the CCLR1 and CCLR0 bits in TCR. When TCNT overflows (changes from H'FF to H'00), the OVF bit in TCSR is set to 1. TCNT is initialized to H'00.

#### 10.3.2 Time Constant Register A (TCORA)

TCORA is an 8-bit readable/writable register. TCORA\_0 and TCORA\_1 comprise a single 16-bit register, so they can be accessed together by word access. TCORA is continually compared with the value in TCNT. When a match is detected, the corresponding compare-match flag A (CMFA) in TCSR is set to 1. Note however that comparison is disabled during the T2 state of a TCORA write cycle. The timer output from the TMO pin can be freely controlled by these compare-match A signals and the settings of output select bits OS1 and OS0 in TCSR. TCORA is initialized to HTFF.

#### 10.3.3 Time Constant Register B (TCORB)

TCORB is an 8-bit readable/writable register. TCORB\_0 and TCORB\_1 comprise a single 16-bit register, so they can be accessed together by word access. TCORB is continually compared with the value in TCNT. When a match is detected, the corresponding compare-match flag B (CMFB) in TCSR is set to 1. Note however that comparison is disabled during the T2 state of a TCORB write cycle. The timer output from the TMO pin can be freely controlled by these compare-match B signals and the settings of output select bits OS3 and OS2 in TCSR. TCORB is initialized to HFF.

## 10.3.4 Timer Control Register (TCR)

TCR selects the TCNT clock source and the condition by which TCNT is cleared, and enables/disables interrupt requests.

Bit	Bit Name	Initial Value	R/W	Description
7	CMIEB	0	R/W	Compare-Match Interrupt Enable B
				Selects whether the CMFB interrupt request (CMIB) is enabled or disabled when the CMFB flag in TCSR is set to 1.
				0: CMFB interrupt request (CMIB) is disabled
				1: CMFB interrupt request (CMIB) is enabled
6	CMIEA	0	R/W	Compare-Match Interrupt Enable A
				Selects whether the CMFA interrupt request (CMIA) is enabled or disabled when the CMFA flag in TCSR is set to 1.
				0: CMFA interrupt request (CMIA) is disabled
				1: CMFA interrupt request (CMIA) is enabled
5	OVIE	0	R/W	Timer Overflow Interrupt Enable
				Selects whether the OVF interrupt request (OVI) is enabled or disabled when the OVF flag in TCSR is set to 1.
				0: OVF interrupt request (OVI) is disabled
				1: OVF interrupt request (OVI) is enabled
4	CCLR1	0	R/W	Counter Clear 1, 0
3	CCLR0	0	R/W	These bits select the method by which the timer counter is cleared.
				00: Clearing is disabled
				01: Cleared on compare-match A
				10: Cleared on compare-match B
				11: Cleared on rising edge of external reset input
2	CKS2	0	R/W	Clock Select 2 to 0
1	CKS1	0	R/W	These bits select the clock input to TCNT and count
0	CKS0	0	R/W	condition, together with the ICKS1 and ICKS0 bits in STCR. For details, see table 10.2.

Table 10.2 Clock Input to TCNT and Count Condition

		TCR		STCR				
Channel	CKS2	CKS1	CKS0	ICKS1	ICKS0	Description		
TMR_0	0	0	0	_	_	Disables clock input		
	0	0	1	_	0	Increments at falling edge of internal clock $\phi/8$		
	0	0	1	_	1	Increments at falling edge of internal clock $\phi/2$		
	0	1	0	_	0	Increments at falling edge of internal clock $\phi/64$		
	0	1	0	_	1	Increments at falling edge of internal clock $\phi/32$		
	0	1	1	_	0	Increments at falling edge of internal clock $\phi/1024$		
	0	1	1	_	1	Increments at falling edge of internal clock $\phi/256$		
	1	0	0	_	_	Increments at overflow signal from TCNT_1*		
TMR_1	0	0	0	_	_	Disables clock input		
	0	0	1	0	_	Increments at falling edge of internal clock $\phi/8$		
	0	0	1	1	_	Increments at falling edge of internal clock $\phi/2$		
	0	1	0	0	_	Increments at falling edge of internal clock $\phi/64$		
	0	1	0	1	_	Increments at falling edge of internal clock $\phi/128$		
	0	1	1	0	_	Increments at falling edge of internal clock $\phi/1024$		
	0	1	1	1	_	Increments at falling edge of internal clock φ/2048		
	1	0	0		_	Increments at compare-match A from TCNT_0*		

		TCR		STCR		
Channel	CKS2	CKS1	CKS0	ICKS1	ICKS0	Description
TMR_Y	0	0	0	_	_	Disables clock input
	0	0	1	_	_	Increments at falling edge of internal clock $\phi/4$
	0	1	0	_	_	Increments at falling edge of internal clock $\phi/256$
	0	1	1	_	_	Increments at falling edge of internal clock $\phi/2048$
	1	0	0	_	_	Disables clock input
Common	1	0	1	_	_	Increments at rising edge of external clock
	1	1	0	_	_	Increments at falling edge of external clock
	1	1	1	_	_	Increments at both rising and falling edges of external clock.

Note: \* If the TMR\_0 clock input is set as the TCNT\_1 overflow signal and the TMR\_1 clock input is set as the TCNT\_0 compare-match signal simultaneously, a count-up clock cannot be generated.

## 10.3.5 Timer Control/Status Register (TCSR)

TCSR indicates the status flags and controls compare-match output.

## • TCSR\_0

Bit	Bit Name	Initial Value	R/W	Description
7	CMFB	0	R/(W)*	Compare-Match Flag B
				[Setting condition]
				When the values of TCNT_0 and TCORB_0 match
				[Clearing conditions]
				• Read CMFB when CMFB = 1, then write 0 in CMFB
6	CMFA	0	R/(W)*	Compare-Match Flag A
				[Setting condition]
				When the values of TCNT_0 and TCORA_0 match
				[Clearing conditions]
				• Read CMFA when CMFA = 1, then write 0 in CMFA
5	OVF	0	R/(W)*	Timer Overflow Flag
				[Setting condition]
				When TCNT_0 overflows from H'FF to H'00
				[Clearing condition]
				Read OVF when OVF = 1, then write 0 in OVF
4	ADTE	0	R/W	A/D Trigger Enable
				Enables or disables A/D converter start requests by compare-match A.
				0: A/D converter start requests by compare-match A are disabled
				1: A/D converter start requests by compare-match A are enabled

Bit	Bit Name	Initial Value	R/W	Description	
3	OS3	0	R/W	Output Select 3, 2	
2	OS2	0	R/W	These bits specify how the TMO0 pin output level is to be changed by compare-match B of TCORB_0 and TCNT_0.	
				00: No change	
				01: 0 is output	
				10: 1 is output	
				11: Output is inverted (toggle output)	
1	OS1	0	R/W	Output Select 1, 0	
0	OS0	0	R/W	These bits specify how the TMO0 pin output level is to be changed by compare-match A of TCORA_0 and TCNT_0.	
				00: No change	
				01: 0 is output	
				10: 1 is output	
				11: Output is inverted (toggle output)	

Note: \* Only 0 can be written for clearing the flag.

## TCSR\_1

Bit	Bit Name	Initial Value	R/W	Description	
7	CMFB	0	R/(W)*	Compare-Match Flag B	
				[Setting condition]	
				When the values of TCNT_1 and TCORB_1 match	
				[Clearing conditions]	
				• Read CMFB when CMFB = 1, then write 0 in CMFB	
6	CMFA	0	R/(W)*	Compare-Match Flag A	
				[Setting condition]	
				When the values of TCNT_1 and TCORA_1 match	
				[Clearing conditions	
				• Read CMFA when CMFA = 1, then write 0 in CMFA	
5	OVF	0	R/(W)*	Timer Overflow Flag	
				[Setting condition]	
				When TCNT_1 overflows from H'FF to H'00	
				[Clearing condition]	
				Read OVF when OVF = 1, then write 0 in OVF	
4	_	1	R	Reserved	
				This bit is always read as 1 and cannot be modified.	
3	OS3	0	R/W	Output Select 3, 2	
2	OS2	0	R/W	These bits specify how the TMO1 pin output level is to be changed by compare-match B of TCORB_1 and TCNT_1.	
				00: No change	
				01: 0 is output	
				10: 1 is output	
				11: Output is inverted (toggle output)	

Bit	Bit Name	Initial Value	R/W	Description
1	OS1	0	R/W	Output Select 1, 0
0	OS0	0	R/W	These bits specify how the TMO1 pin output level is to be changed by compare-match A of TCORA_1 and TCNT_1.
				00: No change
				01: 0 is output
				10: 1 is output
				11: Output is inverted (toggle output)

Note: \* Only 0 can be written for clearing the flag.

## • TCSR\_Y

Bit	Bit Name	Initial Value	R/W	Description
7	CMFB	0	R/(W)*1	Compare-Match Flag B
				[Setting condition]
				When the values of TCNT_Y and TCORB_Y match
				[Clearing conditions]
				• Read CMFB when CMFB = 1, then write 0 in CMFB
6	CMFA	0	R/(W)*1	Compare-Match Flag A
				[Setting condition]
				When the values of TCNT_Y and TCORA_Y match
				[Clearing conditions]
				• Read CMFA when CMFA = 1, then write 0 in CMFA
5	OVF	0	R/(W)*1	Timer Overflow Flag
				[Setting condition]
				When TCNT_Y overflows from H'FF to H'00
				[Clearing condition]
				Read OVF when OVF = 1, then write 0 in OVF
4		0	R	Reserved
				This bit is always read as 0 and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description	
3	OS3	0	R/W	Output Select 3, 2	
2	OS2	0	R/W	These bits specify how the TMOY pin*2 output level is to be changed by compare-match B of TCORB_Y and TCNT_Y.	
				00: No change	
				01: 0 is output	
				10: 1 is output	
				11: Output is inverted (toggle output)	
1	OS1	0	R/W	Output Select 1, 0	
0	OS0	0	R/W	These bits specify how the TMOY pin*2 output level is to be changed by compare-match A of TCORA_Y and TCNT_Y.	
				00: No change	
				01: 0 is output	
				10: 1 is output	
				11: Output is inverted (toggle output)	

Notes: 1. Only 0 can be written for clearing the flag.

2. This product does not have a TMOY external output pin.

### 10.3.6 Timer Input Select Register (TISR)

TISR enables or disables to input a signal on the external counter clock/external counter reset input pin.

Bit	Bit Name	Initial Value	R/W	Description
7	_	All 1	R/(W)	Reserved
to 1				The initial value should not be modified.
0	IS	0	R/W	Input Select
				Enables or disables to input a signal to be used as an external clock or an external reset for the TMR_Y counter on the TMIY (TMCIY/TMRIY) pin.
				0: Disables a signal input on the TMIY (TMCIY/TMRIY) pin
				Enables a signal input on the TMIY (TMCIY/TMRIY)     pin

### 10.4 Operation

### 10.4.1 Pulse Output

Figure 10.3 shows an example for outputting an arbitrary duty pulse.

- 1. Clear the CCLR1 bit in TCR to 0 so that TCNT is cleared according to the compare match of TCORA, and then set the CCLR0 bit to 1.
- 2. Set the OS3 to OS0 bits in TCSR to B'0110 so that 1 is output according to the compare match of TCORA and 0 is output according to the compare match of TCORB.

According to the above settings, the waveforms with the TCORA cycle and TCORB pulse width can be output without the intervention of software.

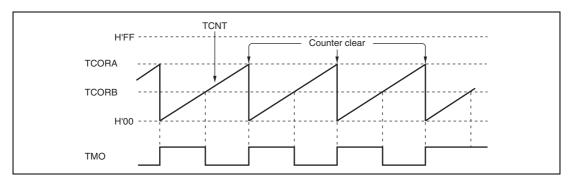

Figure 10.3 Pulse Output Example

## 10.5 Operation Timing

### 10.5.1 TCNT Count Timing

Figure 10.4 shows the TCNT count timing with an internal clock source. Figure 10.5 shows the TCNT count timing with an external clock source. The pulse width of the external clock signal must be at least 1.5 system clocks ( $\phi$ ) for a single edge and at least 2.5 system clocks ( $\phi$ ) for both edges. The counter will not increment correctly if the pulse width is less than these values.

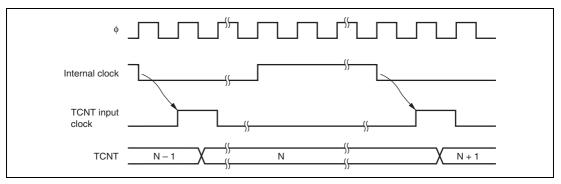

Figure 10.4 Count Timing for Internal Clock Input

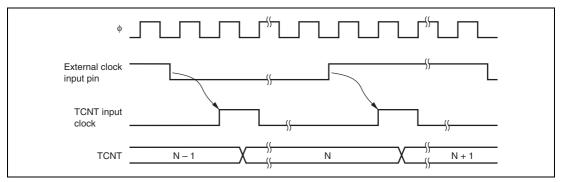

Figure 10.5 Count Timing for External Clock Input (Both Edges)

### 10.5.2 Timing of CMFA and CMFB Setting at Compare-Match

The CMFA and CMFB flags in TCSR are set to 1 by a compare-match signal generated when the TCNT and TCOR values match. The compare-match signal is generated at the last state in which the match is true, just when the timer counter is updated. Therefore, when TCNT and TCOR match, the compare-match signal is not generated until the next TCNT input clock. Figure 10.6 shows the timing of CMF flag setting.

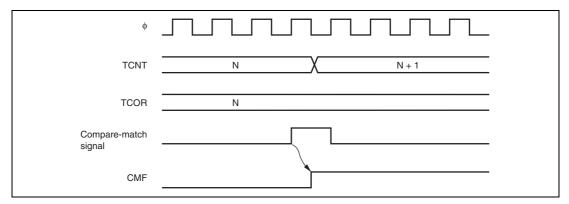

Figure 10.6 Timing of CMF Setting at Compare-Match

#### 10.5.3 Timing of Timer Output at Compare-Match

When a compare-match signal occurs, the timer output changes as specified by the OS3 to OS0 bits in TCSR. Figure 10.7 shows the timing of timer output when the output is set to toggle by a compare-match A signal.

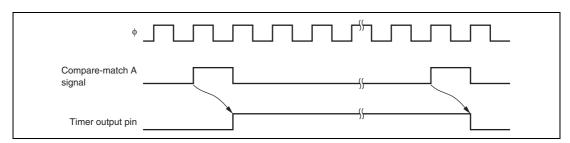

Figure 10.7 Timing of Toggled Timer Output by Compare-Match A Signal

#### 10.5.4 Timing of Counter Clear at Compare-Match

TCNT is cleared when compare-match A or compare-match B occurs, depending on the setting of the CCLR1 and CCLR0 bits in TCR. Figure 10.8 shows the timing of clearing the counter by a compare-match.

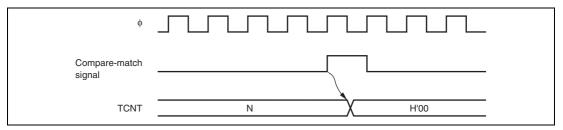

Figure 10.8 Timing of Counter Clear by Compare-Match

#### 10.5.5 TCNT External Reset Timing

TCNT is cleared at the rising edge of an external reset input, depending on the settings of the CCLR1 and CCLR0 bits in TCR. The width of the clearing pulse must be at least 1.5 states. Figure 10.9 shows the timing of clearing the counter by an external reset input.

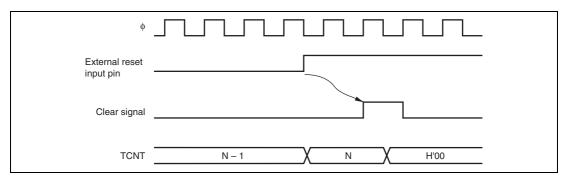

Figure 10.9 Timing of Counter Clear by External Reset Input

## 10.5.6 Timing of Overflow Flag (OVF) Setting

The OVF bit in TCSR is set to 1 when the TCNT overflows (changes from H'FF to H'00). Figure 10.10 shows the timing of OVF flag setting.

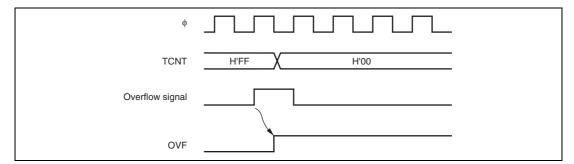

Figure 10.10 Timing of OVF Flag Setting

### 10.6 Operation with Cascaded Connection

If bits CKS2 to CKS0 in either TCR\_0 or TCR\_1 are set to B'100, the 8-bit timers of the two channels are cascaded. With this configuration, a single 16-bit timer can be used (16-bit count mode) or the compare-matches of the 8-bit timer of channel 0 can be counted by the 8-bit timer of channel 1 (compare-match count mode).

#### **10.6.1 16-Bit Count Mode**

When bits CKS2 to CKS0 in TCR\_0 are set to B'100, the timer functions as a single 16-bit timer with channel 0 occupying the upper 8 bits and channel 1 occupying the lower 8 bits.

#### **Setting of Compare-Match Flags:**

- The CMF flag in TCSR 0 is set to 1 when a 16-bit compare-match occurs.
- The CMF flag in TCSR 1 is set to 1 when a lower 8-bit compare-match occurs.

#### **Counter Clear Specification:**

- If the CCLR1 and CCLR0 bits in TCR\_0 have been set for counter clear at compare-match, the 16-bit counter (TCNT\_0 and TCNT\_1 together) is cleared when a 16-bit compare-match occurs. The 16-bit counter (TCNT\_0 and TCNT\_1 together) is also cleared when counter clear by the TMI0 pin has been set.
- The settings of the CCLR1 and CCLR0 bits in TCR\_1 are ignored. The lower 8 bits cannot be cleared independently.

### **Pin Output:**

- Control of output from the TMO0 pin by bits OS3 to OS0 in TCSR\_0 is in accordance with the 16-bit compare-match conditions.
- Control of output from the TMO1 pin by bits OS3 to OS0 in TCSR\_1 is in accordance with the lower 8-bit compare-match conditions.

### 10.6.2 Compare-Match Count Mode

When bits CKS2 to CKS0 in TCR\_1 are B'100, TCNT\_1 counts the occurrence of compare-match A for channel 0. Channels 0 and 1 are controlled independently. Conditions such as setting of the CMF flag, generation of interrupts, output from the TMO pin, and counter clearing are in accordance with the settings for each channel.

## 10.7 Interrupt Sources

TMR\_0, TMR\_1, and TMR\_Y can generate three types of interrupts: CMIA, CMIB, and OVI. Table 10.3 shows the interrupt sources and priorities. Each interrupt source can be enabled or disabled independently by interrupt enable bits in TCR or TCSR. Independent signals are sent to the interrupt controller for each interrupt.

Table 10.3 Interrupt Sources of 8-Bit Timers TMR\_0, TMR\_1, TMR\_Y, and TMR\_X

Channel	Name	Interrupt Source	Interrupt Flag	Interrupt Priority
TMR_0	CMIA0	TCORA_0 compare-match	CMFA	High
	CMIB0	TCORB_0 compare-match	CMFB	<b>↑</b>
	OVI0	TCNT_0 overflow	OVF	_
TMR_1	CMIA1	TCORA_1 compare-match	CMFA	_
	CMIB1	TCORB_1 compare-match	CMFB	_
	OVI1	TCNT_1 overflow	OVF	_
TMR_Y	CMIAY	TCORA_Y compare-match	CMFA	_
	CMIBY	TCORB_Y compare-match	CMFB	_
	OVIY	TCNT_Y overflow	OVF	Low

## 10.8 Usage Notes

#### 10.8.1 Conflict between TCNT Write and Clear

If a counter clear signal is generated during the T2 state of a TCNT write cycle as shown in figure 10.11, clearing takes priority, so that the counter is cleared and the write is not performed.

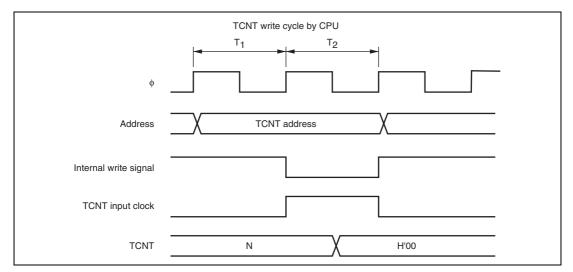

Figure 10.11 Conflict between TCNT Write and Clear

#### 10.8.2 Conflict between TCNT Write and Increment

If a TCNT input clock is generated during the T2 state of a TCNT write cycle as shown in figure 10.12, the write takes priority and the counter is not incremented.

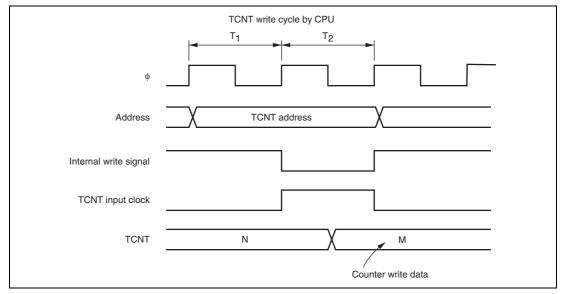

Figure 10.12 Conflict between TCNT Write and Increment

### 10.8.3 Conflict between TCOR Write and Compare-Match

If a compare-match occurs during the T2 state of a TCOR write cycle as shown in figure 10.13, the TCOR write takes priority and the compare-match signal is disabled.

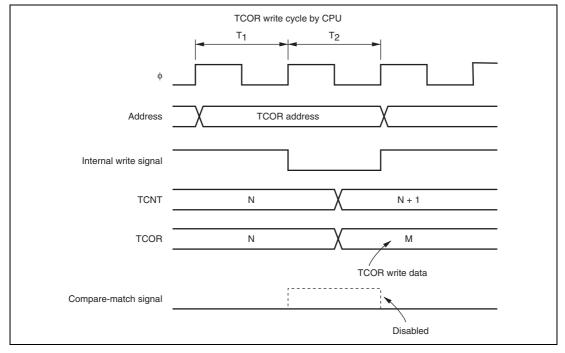

Figure 10.13 Conflict between TCOR Write and Compare-Match

#### 10.8.4 Conflict between Compare-Matches A and B

If compare-matches A and B occur at the same time, the 8-bit timer operates in accordance with the priorities for the output states set for compare-match A and compare-match B, as shown in table 10.4.

**Table 10.4** Timer Output Priorities

Output Setting	Priority
Toggle output	High
1 output	
0 output	
No change	Low

#### 10.8.5 Switching of Internal Clocks and TCNT Operation

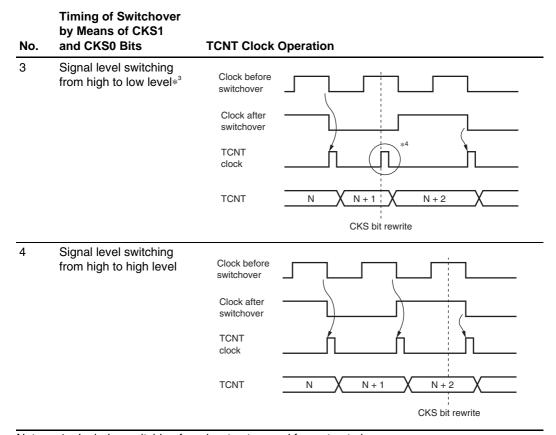

TCNT may increment erroneously when internal clocks are switched. Table 10.5 shows the relationship between the timing at which internal clocks are switched (by writing to the CKS1 and CKS0 bits) and the TCNT operation.

When the TCNT clock is generated from an internal clock, the falling edge of the internal clock pulse is always monitored. If the signal levels of the clocks before and after switching change from high to low as shown in item 3, the change is considered as the falling edge. Therefore, a TCNT clock pulse is generated and TCNT is incremented.

The erroneous incrementation of TCNT can also happen when switching between internal and external clocks

Table 10.5 Switching of Internal Clocks and TCNT Operation

**Timing of Changing** Signal Levels by CKS1 and CKS0 **TCNT Clock Operation** No. 1 Signal level switching Clock before from low to low level\*1 switchover Clock after switchover **TCNT** clock Ν **TCNT** N + 1CKS bit rewrite 2 Signal level switching Clock before from low to high level\*2 switchover Clock after switchover **TCNT** clock **TCNT** Ν N + 1N + 2CKS bit rewrite

Notes: 1. Includes switching from low to stop, and from stop to low.

- 2. Includes switching from stop to high.
- 3. Includes switching from high to stop.
- Generated on the assumption that the switchover is a falling edge; TCNT is incremented.

### 10.8.6 Mode Setting with Cascaded Connection

If the 16-bit count mode and compare-match count mode are set simultaneously, the input clock pulses for TCNT\_0 and TCNT\_1 are not generated, and thus the counters will stop operating. Simultaneous setting of these two modes should therefore be avoided.

### 10.8.7 Module Stop Mode Setting

TMR operation can be enabled or disabled using the module stop control register. The initial setting is for TMR operation to be halted. Register access is enabled by canceling the module stop mode. For details, refer to section 18, Power-Down Modes.

# Section 11 Watchdog Timer (WDT)

This LSI incorporates two watchdog timer channels (WDT\_0 and WDT\_1). The watchdog timer can generate an internal reset signal or an internal NMI interrupt signal if a system crash prevents the CPU from writing to the timer counter, thus allowing it to overflow. Simultaneously, it can output an overflow signal ( $\overline{RESO}$ ) externally.

When this watchdog function is not needed, the WDT can be used as an interval timer. In interval timer operation, an interval timer interrupt is generated each time the counter overflows. A block diagram of the WDT\_0 and WDT\_1 is shown in figure 11.1.

#### 11.1 Features

- Selectable from eight (WDT 0) or 16 (WDT 1) counter input clocks.
- Switchable between watchdog timer mode and interval timer mode

#### **Watchdog Timer Mode:**

- If the counter overflows, an internal reset or an internal NMI interrupt is generated.
- When the LSI is selected to be internally reset at counter overflow, a low level signal is output from the RESO pin if the counter overflows. (Available only for the H8S/2144B.)

#### **Internal Timer Mode:**

• If the counter overflows, an internal timer interrupt (WOVI) is generated.

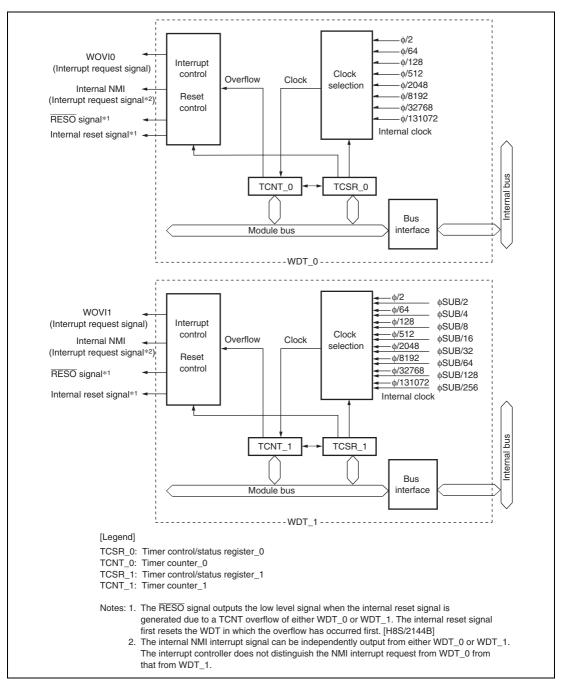

Figure 11.1 Block Diagram of WDT

## 11.2 Input/Output Pins

The WDT has the pins listed in table 11.1.

**Table 11.1 Pin Configuration** 

Name	Symbol	I/O	Function
Reset output pin	RESO	Output	Outputs the counter overflow signal in watchdog timer mode (Available only for the H8S/2144B)
External sub-clock input pin	EXCL	Input	Inputs the clock pulses to the WDT_1 prescaler counter

## 11.3 Register Descriptions

The WDT has the following registers. To prevent accidental overwriting, TCSR and TCNT have to be written to in a method different from normal registers. For details, refer to section 11.6.1, Notes on Register Access. For details on the system control register, refer to section 3.2.2, System Control Register (SYSCR).

- Timer counter (TCNT)
- Timer control/status register (TCSR)

#### 11.3.1 Timer Counter (TCNT)

TCNT is an 8-bit readable/writable up-counter.

TCNT is initialized to H'00 when the TME bit in the timer control/status register (TCSR) is cleared to 0.

## 11.3.2 Timer Control/Status Register (TCSR)

TCSR selects the clock source to be input to TCNT, and the timer mode.

## • TCSR\_0

D:4	Dit Name	Initial	R/W	Description
Bit	Bit Name			Description
7	OVF	0	R/(W)*1	Overflow Flag
				Indicates that TCNT has overflowed (changes from H'FF to H'00).
				[Setting condition]
				When TCNT overflows (changes from H'FF to H'00)
				However, when internal reset request generation is selected in watchdog timer mode, OVF is cleared automatically by the internal reset.
				[Clearing conditions]
				<ul> <li>When TCSR is read when OVF = 1*2, then 0 is written to OVF</li> </ul>
				When 0 is written to TME
6	WT/IT	0	R/W	Timer Mode Select
				Selects whether the WDT is used as a watchdog timer or interval timer.
				0: Interval timer mode
				1: Watchdog timer mode
5	TME	0	R/W	Timer Enable
				When this bit is set to 1, TCNT starts counting.
				When this bit is cleared, TCNT stops counting and is initialized to H'00.
4	_	0	R/(W)	Reserved
				The initial value should not be modified.
3	RST/NMI	0	R/W	Reset or NMI
				Selects to request an internal reset or an NMI interrupt when TCNT has overflowed.
				0: An NMI interrupt is requested
				1: An internal reset is requested
	•	•	•	

Bit	Bit Name	Initial Value	R/W	Description
2	CKS2	0	R/W	Clock Select 2 to 0
1	CKS1	0	R/W	Selects the clock source to be input to. The overflow
0	CKS0	0	R/W	frequency for $\phi$ = 10 MHz is enclosed in parentheses.
				000: φ/2 (frequency: 51.2 μs)
				001: φ/64 (frequency: 1.64 ms)
				010: φ/128 (frequency: 3.28 ms)
				011: φ/512 (frequency: 13.1 ms)
				100: φ/2048 (frequency: 52.4 ms)
				101: φ/8192 (frequency: 209.7 ms)
				110: φ/32768 (frequency: 0.84 s)
				111: φ/131072 (frequency: 3.36 s)

Notes: 1. Only 0 can be written, to clear the flag.

2. When OVF is polled with the interval timer interrupt disabled, OVF = 1 must be read at least twice.

# • TCSR\_1

Bit	Bit Name	Initial Value	R/W	Description
7	OVF	0	R/(W)*1	Overflow Flag
				Indicates that TCNT has overflowed (changes from H'FF to H'00).
				[Setting condition]
				When TCNT overflows (changes from H'FF to H'00)
				However, when internal reset request generation is selected in watchdog timer mode, OVF is cleared automatically by the internal reset.
				[Clearing conditions]
				When TCSR is read when OVF = $1*^2$ , then 0 is written to OVF
				When 0 is written to TME
6	WT/IT	0	R/W	Timer Mode Select
				Selects whether the WDT is used as a watchdog timer or interval timer.
				0: Interval timer mode
				1: Watchdog timer mode
5	TME	0	R/W	Timer Enable
				When this bit is set to 1, TCNT starts counting.
				When this bit is cleared, TCNT stops counting and is initialized to H'00.
4	PSS	0	R/W	Prescaler Select
				Selects the clock source to be input to TCNT.
				0: Counts the divided cycle of $\phi$ -based prescaler (PSM)
				1: Counts the divided cycle of φSUB-based prescaler (PSS)
3	RST/NMI	0	R/W	Reset or NMI
				Selects to request an internal reset or an NMI interrupt when TCNT has overflowed.
				0: An NMI interrupt is requested
				1: An internal reset is requested

Bit	Bit Name	Initial Value	R/W	Description
2	CKS2	0	R/W	Clock Select 2 to 0
1	CKS1	0	R/W	Selects the clock source to be input to TCNT. The
0	CKS0	0	R/W	overflow cycle for $\phi$ = 10 MHz and $\phi$ SUB = 32.768 kHz is enclosed in parentheses.
				When PSS = 0:
				000: φ/2 (frequency: 51.2 μs)
				001: φ/64 (frequency: 1.64 ms)
				010: φ/128 (frequency: 3.28 ms)
				011: φ/512 (frequency: 13.1 ms)
				100: φ/2048 (frequency: 52.4 ms)
				101: φ/8192 (frequency: 209.7 ms)
				110: φ/32768 (frequency: 0.84 s)
				111: φ/131072 (frequency: 3.36 s)
				When PSS = 1:
				000: φSUB/2 (cycle: 15.6 ms)
				001: φSUB/4 (cycle: 31.3 ms)
				010: φSUB/8 (cycle: 62.5 ms)
				011: φSUB/16 (cycle: 125 ms)
				100: φSUB/32 (cycle: 250 ms)
				101: φSUB/64 (cycle: 500 ms)
				110: φSUB/128 (cycle: 1 s)
				111: φ/256 (cycle: 2 s)

Notes: 1. Only 0 can be written, to clear the flag.

2. When OVF is polled with the interval timer interrupt disabled, OVF = 1 must be read at least twice.

## 11.4 Operation

#### 11.4.1 Watchdog Timer Mode

To use the WDT as a watchdog timer, set the WT/IT bit and the TME bit in TCSR to 1. While the WDT is used as a watchdog timer, if TCNT overflows without being rewritten because of a system malfunction or another error, an internal reset or NMI interrupt request is generated. TCNT does not overflow while the system is operating normally. Software must prevent TCNT overflows by rewriting the TCNT value (normally be writing H'00) before overflows occurs.

If the RST/ $\overline{\text{NMI}}$  bit of TCSR is set to 1, when the TCNT overflows, an internal reset signal for this LSI is issued for 518 system clocks, and the low level signal is simultaneously output from the  $\overline{\text{RESO}}$  pin for 132 states, as shown in figure 11.2. If the RST/ $\overline{\text{NMI}}$  bit is cleared to 0, when the TCNT overflows, an NMI interrupt request is generated. Here, the output from the  $\overline{\text{RESO}}$  pin remains high.

An internal reset request from the watchdog timer and a reset input from the  $\overline{RES}$  pin are processed in the same vector. Reset source can be identified by the XRST bit status in SYSCR. If a reset caused by a signal input to the  $\overline{RES}$  pin occurs at the same time as a reset caused by a WDT overflow, the  $\overline{RES}$  pin reset has priority and the XRST bit in SYSCR is set to 1.

An NMI interrupt request from the watchdog timer and an interrupt request from the NMI pin are processed in the same vector. Do not handle an NMI interrupt request from the watchdog timer and an interrupt request from the NMI pin at the same time.

Note: \* The  $\overline{\text{RESO}}$  pin is available only for the H8S/2144B.

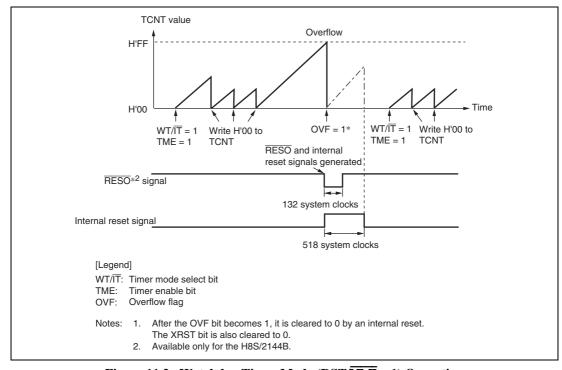

Figure 11.2 Watchdog Timer Mode (RST/ $\overline{NMI}$  = 1) Operation

#### 11.4.2 Interval Timer Mode

When the WDT is used as an interval timer, an interval timer interrupt (WOVI) is generated each time the TCNT overflows, as shown in figure 11.3. Therefore, an interrupt can be generated at intervals.

When the TCNT overflows in interval timer mode, an interval timer interrupt (WOVI) is requested at the same time the OVF bit of TCSR is set to 1. The timing is shown figure 11.4.

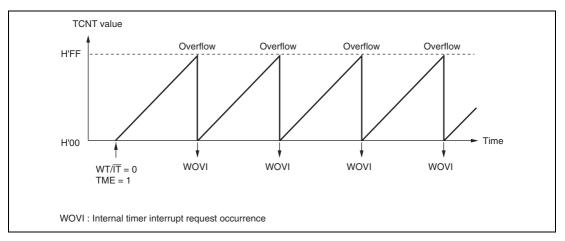

Figure 11.3 Interval Timer Mode Operation

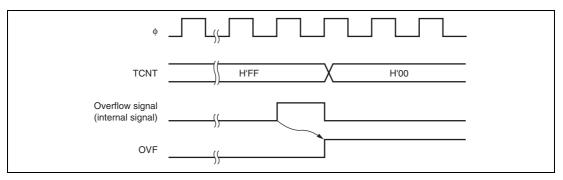

Figure 11.4 OVF Flag Set Timing

#### 11.4.3 RESO Signal Output Timing (Available for H8S/2144B)

When TCNT overflows in watchdog timer mode, the OVF bit in TCSR is set to 1. When the RST/ $\overline{\text{NMI}}$  bit is 1 here, the internal reset signal is generated for the entire LSI. At the same time, the low level signal is output from the  $\overline{\text{RESO}}$  pin. The timing is shown in figure 11.5.

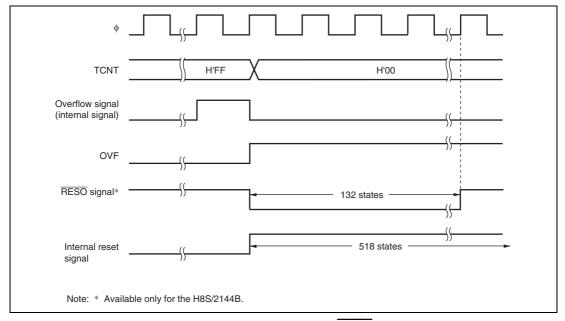

Figure 11.5 Output Timing of RESO signal

# 11.5 Interrupt Sources

During interval timer mode operation, an overflow generates an interval timer interrupt (WOVI). The interval timer interrupt is requested whenever the OVF flag is set to 1 in TCSR. OVF must be cleared to 0 in the interrupt handling routine.

When the NMI interrupt request is selected in watchdog timer mode, an NMI interrupt request is generated by an overflow.

**Table 11.2 WDT Interrupt Source** 

Name	Interrupt Source	Interrupt Flag
WOVI	TCNT overflow	OVF

## 11.6 Usage Notes

#### 11.6.1 Notes on Register Access

The watchdog timer's registers, TCNT and TCSR differ from other registers in being more difficult to write to. The procedures for writing to and reading from these registers are given below.

Writing to TCNT and TCSR (Example of WDT\_0): These registers must be written to by a word transfer instruction. They cannot be written to by a byte transfer instruction.

TCNT and TCSR both have the same write address. Therefore, satisfy the relative condition shown in figure 11.6 to write to TCNT or TCSR. To write to TCNT, the upper bytes must contain the value H'5A and the lower bytes must contain the write data before the transfer instruction execution. To write to TCSR, the upper bytes must contain the value H'A5 and the lower bytes must contain the write data.

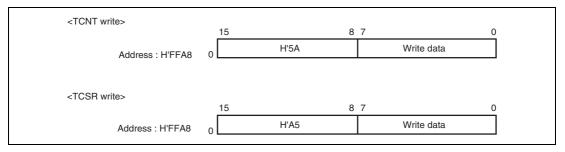

Figure 11.6 Writing to TCNT and TCSR (WDT\_0)

**Reading from TCNT and TCSR (Example of WDT\_0):** These registers are read in the same way as other registers. The read address is H'FFA8 for TCSR and H'FFA9 for TCNT.

#### 11.6.2 Conflict between Timer Counter (TCNT) Write and Increment

If a timer counter clock pulse is generated during the T2 state of a TCNT write cycle, the write takes priority and the timer counter is not incremented. Figure 11.7 shows this operation.

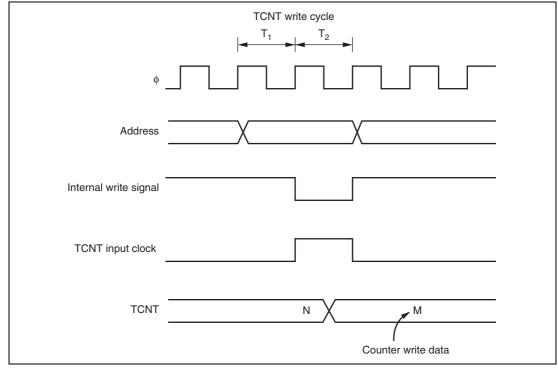

Figure 11.7 Conflict between TCNT Write and Increment

## 11.6.3 Changing Values of CKS2 to CKS0 Bits

If bits CKS2 to CKS0 in TCSR are written to while the WDT is operating, errors could occur in the incrementation. Software must stop the watchdog timer (by clearing the TME bit to 0) before changing the values of bits CKS2 to CKS0.

## 11.6.4 Switching between Watchdog Timer Mode and Interval Timer Mode

If the mode is switched from watchdog timer to interval timer, while the WDT is operating, errors could occur in the incrementation. Software must stop the watchdog timer (by clearing the TME bit to 0) before switching the mode.

#### 11.6.5 System Reset by RESO Signal (Available for H8S/2144B)

Inputting the  $\overline{RESO}$  output signal to the  $\overline{RESO}$  pin of this LSI prevents the LSI from being initialized correctly; the  $\overline{RESO}$  signal must not be logically connected to the  $\overline{RESO}$  pin of the LSI. To reset the entire system by the  $\overline{RESO}$  signal, use the circuit as shown in figure 11.8.

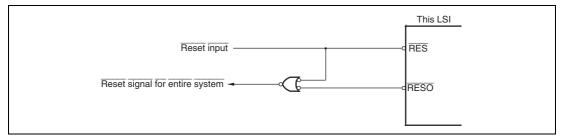

Figure 11.8 Sample Circuit for Resetting System by RESO Signal

# 11.6.6 Counter Values during Transitions between High-Speed, Sub-Active, and Watch Modes

When WDT\_1 is used as a clock counter and is allowed to transit between high-speed mode and sub-active or watch mode, the counter does not display the correct value due to internal clock switching.

Specifically, when transiting from high-speed mode to sub-active or watch mode, that is, when the control clock for WDT\_1 switches from the main clock to the sub-clock, the counter incrementing timing is delayed for approximately two to three clock cycles.

Similarly, when transiting from sub-active or watch mode to high-speed mode, the clock is not supplied until stabilized internal oscillation is available because the main clock oscillator is halted in sub-clock mode. The counter is therefore prevented from incrementing for the time specified by the STS2 to STS0 bits in SBYCR after internal oscillation starts, thus producing counter value differences for this time.

Special care must be taken when using WDT\_1 as a clock counter. Note that no counter value difference is produced while operated in the same mode.

# Section 12 Serial Communication Interface (SCI and IrDA)

This LSI has three independent serial communication interface (SCI) channels. The SCI can handle both asynchronous and clock synchronous serial communication. Asynchronous serial data communication can be carried out with standard asynchronous communication chips such as a Universal Asynchronous Receiver/Transmitter (UART) or Asynchronous Communication Interface Adapter (ACIA). A function is also provided for serial communication between processors (multiprocessor communication function) in asynchronous mode.

SCI\_2 can handle communication using the waveform based on the Infrared Data Association (IrDA) standard version 1.0.

#### 12.1 Features

- · Choice of asynchronous or clock synchronous serial communication mode
- Full-duplex communication capability
   The transmitter and receiver are mutually independent, enabling transmission and reception to be executed simultaneously. Double-buffering is used in both the transmitter and the receiver.
  - be executed simultaneously. Double-buffering is used in both the transmitter and the receiver, enabling continuous transmission and continuous reception of serial data.
- The on-chip baud rate generator allows any bit rate to be selected An external clock can be selected as a transfer clock source.
- Choice of LSB-first or MSB-first transfer (except in the case of asynchronous mode 7-bit data)
- Four interrupt sources
   Four interrupt sources transmit-end, transmit-data-empty, receive-data-full, and receive error

#### **Asynchronous Mode:**

- Data length: 7 or 8 bits
- Stop bit length: 1 or 2 bits
- Parity: Even, odd, or none
- Receive error detection: Parity, overrun, and framing errors
- Break detection: Break can be detected by reading the RxD pin level directly in case of a framing error

#### **Clock Synchronous Mode:**

- Data length: 8 bits
- Receive error detection: Overrun errors
- Serial data communication with other LSIs that have the clock synchronized communication function

A block diagram of the SCI is shown in figure 12.1.

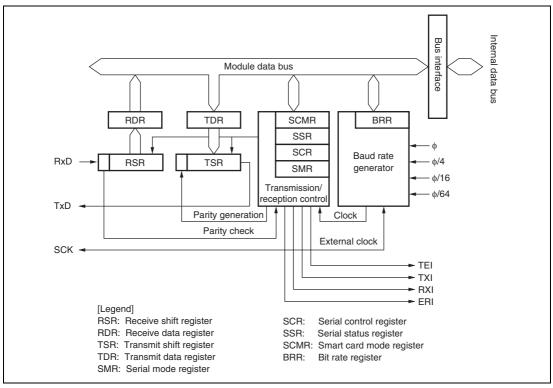

Figure 12.1 Block Diagram of SCI

## 12.2 Input/Output Pins

Table 12.1 shows the input/output pins for each SCI channel.

**Table 12.1 Pin Configuration** 

Channel	Symbol*	Input/Output	Function
0	SCK0	Input/Output	Channel 0 clock input/output
	RxD0	Input	Channel 0 receive data input
	TxD0	Output	Channel 0 transmit data output
1	SCK1	Input/Output	Channel 1 clock input/output
	RxD1	Input	Channel 1 receive data input
	TxD1	Output	Channel 1 transmit data output
2	SCK2	Input/Output	Channel 2 clock input/output
	RxD2/IrRxD	Input	Channel 2 receive data input (normal/IrDA)
	TxD2/IrTxD	Output	Channel 2 transmit data output (normal/IrDA)

Note \* Pin names SCK, RxD, and TxD are used in the text for all channels, omitting the channel designation.

## 12.3 Register Descriptions

The SCI has the following registers for each channel.

- Receive shift register (RSR)
- Receive data register (RDR)
- Transmit data register (TDR)
- Transmit shift register (TSR)
- Serial mode register (SMR)
- Serial control register (SCR)
- Serial status register (SSR)
- Serial interface mode register (SCMR)
- Bit rate register (BRR)
- Keyboard comparator control register (KBCOMP)

#### 12.3.1 Receive Shift Register (RSR)

RSR is a shift register used to receive serial data that converts it into parallel data. When one frame of data has been received, it is transferred to RDR automatically. RSR cannot be directly accessed by the CPU.

#### 12.3.2 Receive Data Register (RDR)

RDR is an 8-bit register that stores receive data. When the SCI has received one frame of serial data, it transfers the received serial data from RSR to RDR where it is stored. After this, RSR can receive the next data. Since RSR and RDR function as a double buffer in this way, continuous receive operations can be performed. After confirming that the RDRF bit in SSR is set to 1, read RDR for only once. RDR cannot be written to by the CPU. RDR is initialized to H'00.

#### 12.3.3 Transmit Data Register (TDR)

TDR is an 8-bit register that stores transmit data. When the SCI detects that TSR is empty, it transfers the transmit data written in TDR to TSR and starts transmission. The double-buffered structures of TDR and TSR enables continuous serial transmission. If the next transmit data has already been written to TDR when one frame of data is transmitted, the SCI transfers the written data to TSR to continue transmission. Although TDR can be read from or written to by the CPU at all times, to achieve reliable serial transmission, write transmit data to TDR for only once after confirming that the TDRE bit in SSR is set to 1. TDR is initialized to H'FF.

## 12.3.4 Transmit Shift Register (TSR)

TSR is a shift register that transmits serial data. To perform serial data transmission, the SCI first transfers transmit data from TDR to TSR, then sends the data to the TxD pin. TSR cannot be directly accessed by the CPU.

## 12.3.5 Serial Mode Register (SMR)

SMR is used to set the SCI's serial transfer format and select the on-chip baud rate generator clock source.

Bit	Bit Name	Initial Value	R/W	Description
7	C/A	0	R/W	Communication Mode
				0: Asynchronous mode
				1: Clock synchronous mode
6	CHR	0	R/W	Character Length (enabled only in asynchronous mode)
				0: Selects 8 bits as the data length.
				1: Selects 7 bits as the data length. LSB-first is fixed and the MSB of TDR is not transmitted in transmission.
				In clock synchronous mode, a fixed data length of 8 bits is used.
5	PE	0	R/W	Parity Enable (enabled only in asynchronous mode)
				When this bit is set to 1, the parity bit is added to transmit data before transmission, and the parity bit is checked in reception. For a multiprocessor format, parity bit addition and checking are not performed regardless of the PE bit setting.
4	O/Ē	0	R/W	Parity Mode (enabled only when the PE bit is 1 in asynchronous mode)
				0: Selects even parity.
				1: Selects odd parity.
3	STOP	0	R/W	Stop Bit Length (enabled only in asynchronous mode)
				Selects the stop bit length in transmission.
				0: 1 stop bit
				1: 2 stop bits
				In reception, only the first stop bit is checked. If the second stop bit is 0, it is treated as the start bit of the next transmit frame.

Bit	Bit Name	Initial Value	R/W	Description
2	MP	0	R/W	Multiprocessor Mode (enabled only in asynchronous mode)
				When this bit is set to 1, the multiprocessor communication function is enabled. The PE bit and O/Ē bit settings are invalid in multiprocessor mode.
1	CKS1	0	R/W	Clock Select 1,0
0	CKS0	0	R/W	These bits select the clock source for the on-chip baud rate generator.
				00: φ clock (n = 0)
				01: φ/4 clock (n = 1)
				10:
				11:
				For the relation between the bit rate register setting and the baud rate, see section 12.3.9, Bit Rate Register (BRR). n is the decimal display of the value of n in BRR.

## 12.3.6 Serial Control Register (SCR)

SCR is a register that performs enabling or disabling of SCI transfer operations and interrupt requests, and selection of the transfer clock source. For details on interrupt requests, refer to section 12.8, Interrupt Sources.

Bit	Bit Name	Initial Value	R/W	Description
7	TIE	0	R/W	Transmit Interrupt Enable
				When this bit is set to 1, a TXI interrupt request is enabled.
6	RIE	0	R/W	Receive Interrupt Enable
				When this bit is set to 1, RXI and ERI interrupt requests are enabled.
5	TE	0	R/W	Transmit Enable
				When this bit is set to 1, transmission is enabled.
4	RE	0	R/W	Receive Enable
				When this bit is set to 1, reception is enabled.
3	MPIE	0	R/W	Multiprocessor Interrupt Enable (enabled only when the MP bit in SMR is 1 in asynchronous mode)
				When this bit is set to 1, receive data in which the multiprocessor bit is 0 is skipped, and setting of the RDRF, FER, and ORER status flags in SSR is disabled. On receiving data in which the multiprocessor bit is 1, this bit is automatically cleared and normal reception is resumed. For details, refer to section 12.5, Multiprocessor Communication Function.
2	TEIE	0	R/W	Transmit End Interrupt Enable
				When this bit is set to 1, a TEI interrupt request is enabled.

Bit	Bit Name	Initial Value	R/W	Description
1	CKE1	0	R/W	Clock Enable 1, 0
0	CKE0	0	R/W	These bits select the clock source and SCK pin function.
				Asynchronous mode
				00: Internal clock
				(SCK pin functions as I/O port.)
				01: Internal clock
				(Outputs a clock of the same frequency as the bit rate from the SCK pin.)
				1X: External clock
				(Inputs a clock with a frequency 16 times the bit rate from the SCK pin.)
				Clock synchronous mode
				0X: Internal clock (SCK pin functions as clock output.)
				1X: External clock (SCK pin functions as clock input.)

[Legend]

X: Don't care

## 12.3.7 Serial Status Register (SSR)

SSR is a register containing status flags of the SCI and multiprocessor bits for transfer. TDRE, RDRF, ORER, PER, and FER can only be cleared.

Bit	Bit Name	Initial Value	R/W	Description
7	TDRE	1	R/(W)*	Transmit Data Register Empty
				Indicates whether TDR contains transmit data.
				[Setting conditions]
				When the TE bit in SCR is 0
				<ul> <li>When data is transferred from TDR to TSR and TDR is ready for data write</li> </ul>
				[Clearing conditions]
				<ul> <li>When 0 is written to TDRE after reading TDRE = 1</li> </ul>
6	RDRF	0	R/(W)*	Receive Data Register Full
				Indicates that receive data is stored in RDR.
				[Setting condition]
				<ul> <li>When serial reception ends normally and receive data is transferred from RSR to RDR</li> </ul>
				[Clearing conditions]
				<ul> <li>When 0 is written to RDRF after reading RDRF = 1</li> </ul>
				The RDRF flag is not affected and retains its previous value when the RE bit in SCR is cleared to 0.
5	ORER	0	R/(W)*	Overrun Error
				[Setting condition]
				<ul> <li>When the next data is received while RDRF =</li> <li>1</li> </ul>
				[Clearing condition]
				When 0 is written to ORER after reading ORER = 1

Bit	Bit Name	Initial Value	R/W	Description
4	FER	0	R/(W)*	Framing Error
				[Setting condition]
				<ul> <li>When the stop bit is 0</li> </ul>
				[Clearing condition]
				<ul> <li>When 0 is written to FER after reading FER =</li> </ul>
				In 2-stop-bit mode, only the first stop bit is checked.
3	PER	0	R/(W)*	Parity Error
				[Setting condition]
				<ul> <li>When a parity error is detected during reception</li> </ul>
				[Clearing condition]
				<ul> <li>When 0 is written to PER after reading PER =</li> <li>1</li> </ul>
2	TEND	1	R	Transmit End
				[Setting conditions]
				When the TE bit in SCR is 0
				<ul> <li>When TDRE = 1 at transmission of the last bit of a 1-byte serial transmit character</li> </ul>
				[Clearing conditions]
				<ul> <li>When 0 is written to TDRE after reading TDRE</li> <li>= 1</li> </ul>
1	MPB	0	R	Multiprocessor Bit
				MPB stores the multiprocessor bit in the receive frame. When the RE bit in SCR is cleared to 0 its previous state is retained.
0	MPBT	0	R/W	Multiprocessor Bit Transfer
				MPBT stores the multiprocessor bit to be added to the transmit frame.

Note: \* Only 0 can be written, to clear the flag.

## 12.3.8 Serial Interface Mode Register (SCMR)

SCMR selects SCI functions and its format.

Bit	Bit Name	Initial Value	R/W	Description
7 to	_	All 1	R	Reserved
4				These bits are always read as 1 and cannot be modified.
3	SDIR	0	R/W	Data Transfer Direction
				Selects the serial/parallel conversion format.
				0: TDR contents are transmitted with LSB-first.
				Receive data is stored as LSB first in RDR.
				1: TDR contents are transmitted with MSB-first.
				Receive data is stored as MSB first in RDR.
				The SDIR bit is valid only when the 8-bit data format is used for transmission/reception; when the 7-bit data format is used, data is always transmitted/received with LSB-first.
2	SINV	0	R/W	Data Invert
				Specifies inversion of the data logic level. The SINV bit does not affect the logic level of the parity bit. When the parity bit is inverted, invert the $O/\overline{E}$ bit in SMR.
				0: TDR contents are transmitted as they are. Receive data is stored as it is in RDR.
				1: TDR contents are inverted before being transmitted. Receive data is stored in inverted form in RDR.
1	_	1	R	Reserved
				This bit is always read as 1 and cannot be modified.
0	SMIF	0	R/W	Serial Communication Interface Mode Select:
				0: Normal asynchronous or clock synchronous mode
				1: Reserved mode

#### 12.3.9 Bit Rate Register (BRR)

BRR is an 8-bit register that adjusts the bit rate. As the SCI performs baud rate generator control independently for each channel, different bit rates can be set for each channel. Table 12.2 shows the relationships between the N setting in BRR and bit rate B for normal asynchronous mode and clock synchronous mode. The initial value of BRR is H'FF, and it can be read from or written to by the CPU at all times.

Table 12.2 Relationships between N Setting in BRR and Bit Rate B

Mode	Bit Rate	Error
Asynchronous mode	$B = \frac{\phi \times 10^6}{64 \times 2^{2n-1} \times (N+1)}$	Error (%) = { $\frac{\phi \times 10^6}{B \times 64 \times 2^{2n-1} \times (N+1)}$ -1} \tag{-1} \times 100
Clock synchronous mode	$B = \frac{\phi \times 10^{6}}{64 \times 2^{2n-1} \times (N+1)}$	_

#### [Legend]

B: Bit rate (bit/s)

N: BRR setting for baud rate generator  $(0 \le N \le 255)$ 

φ: Operating frequency (MHz)

n: Determined by the SMR settings shown in the following table.

SMF	R Setting		
CKS1	CKS0	n	
0	0	0	
0	1	1	
1	0	2	
1	1	3	

Table 12.3 shows sample N settings in BRR in normal asynchronous mode. Table 12.4 shows the maximum bit rate settable for each frequency. Table 12.6 shows sample N settings in BRR in clock synchronous mode. Tables 12.5 and 12.7 show the maximum bit rates with external clock input.

Table 12.3 BRR Settings for Various Bit Rates (Asynchronous Mode)

# 12.3.10 Keyboard Comparator Control Register (KBCOMP)

KBCOMP selects the functions of the SCI and A/D converter.

Bit	Bit Name	Initial Value	R/W	Description
7	IrE	0	R/W	IrDA Enable
				Specifies SCI_2 I/O pins for either normal SCI or IrDA.
				0: TxD2/IrTxD and RxD2/IrRxD pins function as TxD2 and RxD2 pins, respectively
				1: TxD2/IrTxD and RxD2/IrRxD pins function as IrTxD and IrRxD pins, respectively
6	IrCKS2	0	R/W	IrDA Clock Select 2 to 0
5 4		0	R/W R/W	These bits specify the high-level width of the clock pulse during IrTxD output pulse encoding when the IrDA function is enabled.
				000: B × 3/16 (B: Bit rate)
				001: φ /2
				010: φ /4
				011: φ /8
				100: φ /16
				101: φ /32
				110: φ /64
				111: φ /128
3	KBADE	0	R/W	Bits related to the A/D converter
2 1 0	KBCH2 KBCH1 KBCH0	0 0 0	R/W R/W R/W	For details, refer to section 14.3.4, Keyboard Comparator Control Register (KBCOMP).

## 12.4 Operation in Asynchronous Mode

Figure 12.2 shows the general format for asynchronous serial communication. One frame consists of a start bit (low level), followed by transmit/receive data, a parity bit, and finally stop bits (high level). In asynchronous serial communication, the transmission line is usually held in the mark state (high level). The SCI monitors the transmission line, and when it goes to the space state (low level), recognizes a start bit and starts serial communication. Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communication. Both the transmitter and the receiver also have a double-buffered structure, so that data can be read or written during transmission or reception, enabling continuous data transfer and reception.

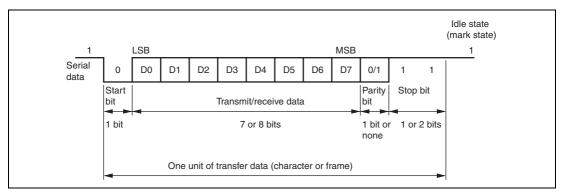

Figure 12.2 Data Format in Asynchronous Communication (Example with 8-Bit Data, Parity, Two Stop Bits)

#### 12.4.1 Data Transfer Format

Table 12.8 shows the data transfer formats that can be used in asynchronous mode. Any of 12 transfer formats can be selected according to the SMR setting. For details on the multiprocessor bit, refer to section 12.5, Multiprocessor Communication Function.

**Table 12.8 Serial Transfer Formats (Asynchronous Mode)** 

SMR Settings				Serial Transmit/Receive Format and Frame Length					
CHR	PE	MP	STOP	1 2 3 4 5 6 7 8 9 10 11 12					
0	0	0	0	S 8-bit data STOP					
0	0	0	1	S 8-bit data STOP STOP					
0	1	0	0	S 8-bit data P STOP					
0	1	0	1	S 8-bit data P STOP STOP					
1	0	0	0	S 7-bit data STOP					
1	0	0	1	S 7-bit data STOP STOP					
1	1	0	0	S 7-bit data P STOP					
1	1	0	1	S 7-bit data P STOP STOP					
0	_	1	0	S 8-bit data MPB STOP					
0	_	1	1	S 8-bit data MPB STOP STOP					
1	_	1	0	S 7-bit data MPB STOP					
1	_	1	1	S 7-bit data MPB STOP STOP					

#### 12.4.2 Receive Data Sampling Timing and Reception Margin in Asynchronous Mode

In asynchronous mode, the SCI operates on a basic clock with a frequency of 16 times the bit rate. In reception, the SCI samples the falling edge of the start bit using the basic clock, and performs internal synchronization. Since receive data is latched internally at the rising edge of the 8th pulse of the basic clock, data is latched at the middle of each bit, as shown in figure 12.3. Thus the reception margin in asynchronous mode is determined by formula (1) below.

$$M = \{ (0.5 - \frac{1}{2N}) - \frac{D - 0.5}{N} (1 + F) - (L - 0.5) F \} \times 100 \quad [\%] \quad \cdots \quad \text{Formula (1)}$$

M: Reception margin (%)

N : Ratio of bit rate to clock (N = 16)

D : Clock duty (D = 0.5 to 1.0)

L: Frame length (L = 9 to 12)

F: Absolute value of clock rate deviation

Assuming values of F = 0 and D = 0.5 in formula (1), the reception margin is determined by the formula below.

$$M = \{0.5 - 1/(2 \times 16)\} \times 100$$
 [%] = 46.875 %

However, this is only the computed value, and a margin of 20% to 30% should be allowed in system design.

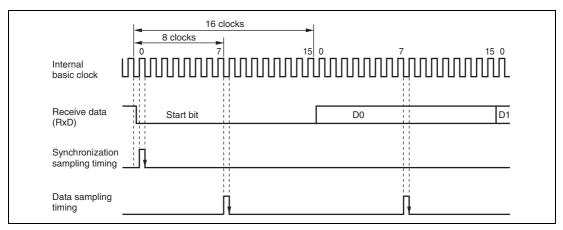

Figure 12.3 Receive Data Sampling Timing in Asynchronous Mode

#### 12.4.3 Clock

Either an internal clock generated by the on-chip baud rate generator or an external clock input at the SCK pin can be selected as the SCI's transfer clock, according to the setting of the  $C/\overline{A}$  bit in SMR and the CKE1 and CKE0 bits in SCR. When an external clock is input at the SCK pin, the clock frequency should be 16 times the bit rate used.

When the SCI is operated on an internal clock, the clock can be output from the SCK pin. The frequency of the clock output in this case is equal to the bit rate, and the phase is such that the rising edge of the clock is in the middle of the transmit data, as shown in figure 12.4.

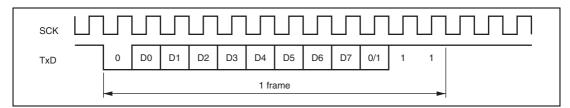

Figure 12.4 Relation between Output Clock and Transmit Data Phase (Asynchronous Mode)

#### **12.4.4** SCI Initialization (Asynchronous Mode)

Before transmitting and receiving data, you should first clear the TE and RE bits in SCR to 0, then initialize the SCI as shown in figure 12.5. When the operating mode, transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, the TDRE flag in SSR is set to 1. Note that clearing the RE bit to 0 does not initialize the contents of the RDRF, PER, FER, and ORER flags in SSR, or the contents of RDR. When an external clock is used in asynchronous mode, the clock must be supplied even during initialization.

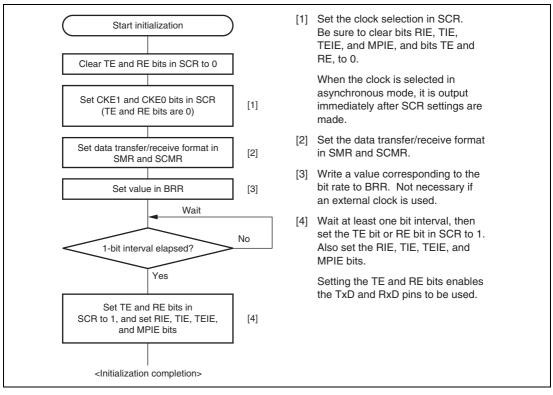

Figure 12.5 Sample SCI Initialization Flowchart

#### 12.4.5 Data Transmission (Asynchronous Mode)

Figure 12.6 shows an example of the operation for transmission in asynchronous mode. In transmission, the SCI operates as described below.

- 1. The SCI monitors the TDRE flag in SSR, and if it is cleared to 0, recognizes that data has been written to TDR, and transfers the data from TDR to TSR.
- 2. After transferring data from TDR to TSR, the SCI sets the TDRE flag to 1 and starts transmission. If the TIE bit in SCR is set to 1 at this time, a transmit data empty interrupt request (TXI) is generated. Because the TXI interrupt routine writes the next transmit data to TDR before transmission of the current transmit data has finished, continuous transmission can be enabled.
- 3. Data is sent from the TxD pin in the following order: start bit, transmit data, parity bit or multiprocessor bit (may be omitted depending on the format), and stop bit.
- 4. The SCI checks the TDRE flag at the timing for sending the stop bit.
- 5. If the TDRE flag is 0, the data is transferred from TDR to TSR, the stop bit is sent, and then serial transmission of the next frame is started.
- 6. If the TDRE flag is 1, the TEND flag in SSR is set to 1, the stop bit is sent, and then the "mark state" is entered in which 1 is output. If the TEIE bit in SCR is set to 1 at this time, a TEI interrupt request is generated.

Figure 12.7 shows a sample flowchart for transmission in asynchronous mode.

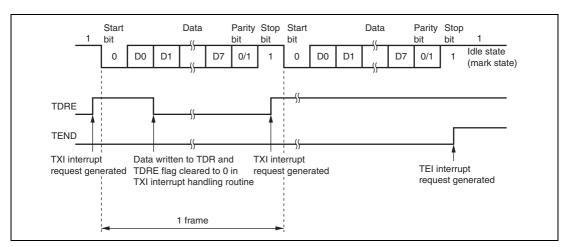

Figure 12.6 Example of SCI Transmit Operation in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

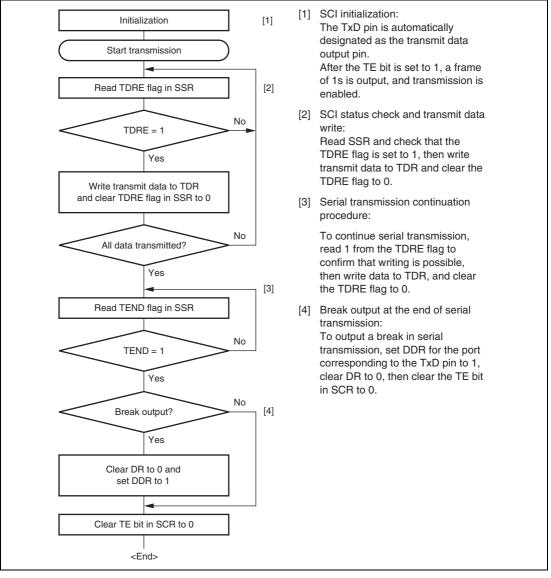

Figure 12.7 Sample Serial Transmission Flowchart

## 12.4.6 Serial Data Reception (Asynchronous Mode)

Figure 12.8 shows an example of the operation for reception in asynchronous mode. In serial reception, the SCI operates as described below.

- 1. The SCI monitors the communication line, and if a start bit is detected, performs internal synchronization, receives receive data in RSR, and checks the parity bit and stop bit.
- 2. If an overrun error (when reception of the next data is completed while the RDRF flag in SSR is still set to 1) occurs, the ORER bit in SSR is set to 1. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR. The RDRF flag remains to be set to 1.
- 3. If a parity error is detected, the PER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated.
- 4. If a framing error (when the stop bit is 0) is detected, the FER bit in SSR is set to 1 and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated.
- 5. If reception finishes successfully, the RDRF bit in SSR is set to 1, and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt request is generated. Because the RXI interrupt routine reads the receive data transferred to RDR before reception of the next receive data has finished, continuous reception can be enabled.

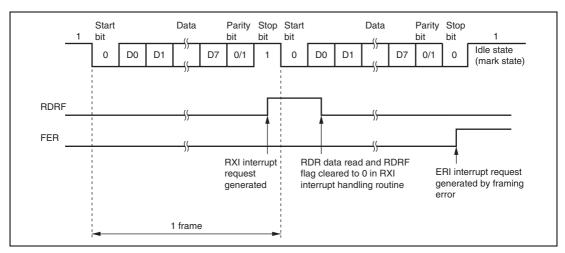

Figure 12.8 Example of SCI Receive Operation in Asynchronous Mode (Example with 8-Bit Data, Parity, One Stop Bit)

Table 12.9 shows the states of the SSR status flags and receive data handling when a receive error is detected. If a receive error is detected, the RDRF flag retains its state before receiving data. Reception cannot be resumed while a receive error flag is set to 1. Accordingly, clear the ORER, FER, PER, and RDRF bits to 0 before resuming reception. Figure 12.9 shows a sample flow chart for serial data reception.

Table 12.9 SSR Status Flags and Receive Data Handling

### **SSR Status Flag**

RDRF*	ORER	FER	PER	Receive Data	Receive Error Type
1	1	0	0	Lost	Overrun error
0	0	1	0	Transferred to RDR	Framing error
0	0	0	1	Transferred to RDR	Parity error
1	1	1	0	Lost	Overrun error + framing error
1	1	0	1	Lost	Overrun error + parity error
0	0	1	1	Transferred to RDR	Framing error + parity error
1	1	1	1	Lost	Overrun error + framing error + parity error

Note: \* The RDRF flag retains the state it had before data reception.

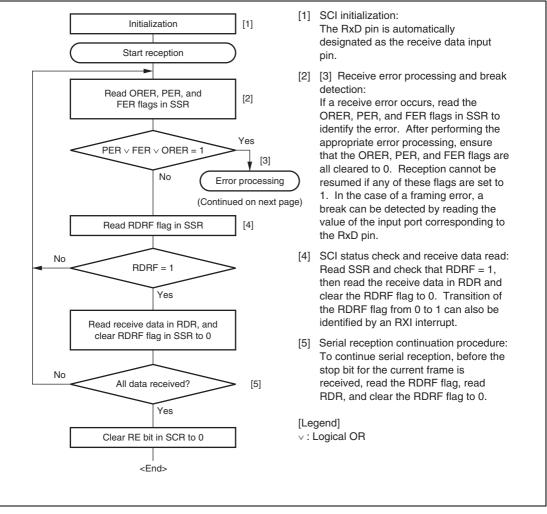

Figure 12.9 Sample Serial Reception Flowchart (1)

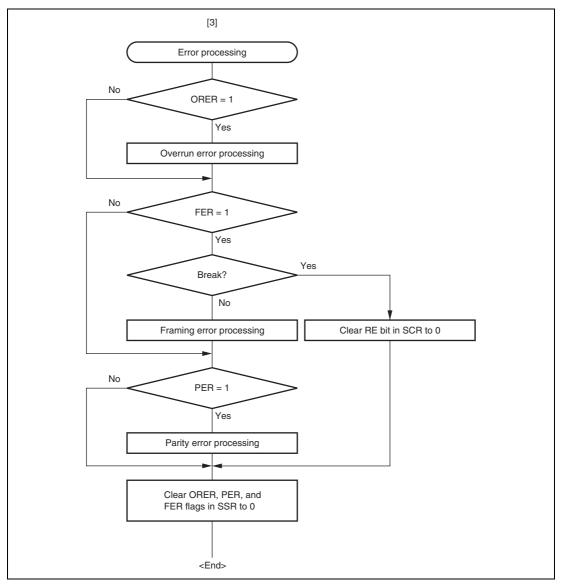

Figure 12.9 Sample Serial Reception Flowchart (2)

# 12.5 Multiprocessor Communication Function

Use of the multiprocessor communication function enables data transfer to be performed among a number of processors sharing communication lines by means of asynchronous serial communication using the multiprocessor format, in which a multiprocessor bit is added to the transfer data. When multiprocessor communication is carried out, each receiving station is addressed by a unique ID code. The serial communication cycle consists of two component cycles: an ID transmission cycle which specifies the receiving station, and a data transmission cycle for the specified receiving station. The multiprocessor bit is used to differentiate between the ID transmission cycle and the data transmission cycle. If the multiprocessor bit is 1, the cycle is an ID transmission cycle, and if the multiprocessor bit is 0, the cycle is a data transmission cycle. Figure 12.10 shows an example of inter-processor communication using the multiprocessor format. The transmitting station first sends the ID code of the receiving station with which it wants to perform serial communication as data with a 1 multiprocessor bit added. It then sends transmit data as data with a 0 multiprocessor bit added. The receiving station skips data until data with a 1 multiprocessor bit is sent. When data with a 1 multiprocessor bit is received, the receiving station compares that data with its own ID. The station whose ID matches then receives the data sent next. Stations whose ID does not match continue to skip data until data with a 1 multiprocessor bit is again received.

The SCI uses the MPIE bit in SCR to implement this function. When the MPIE bit is set to 1, transfer of receive data from RSR to RDR, error flag detection, and setting the SSR status flags, RDRF, FER, and ORER in SSR to 1 are prohibited until data with a 1 multiprocessor bit is received. On reception of a receive character with a 1 multiprocessor bit, the MPB bit in SSR is set to 1 and the MPIE bit is automatically cleared, thus normal reception is resumed. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt is generated.

When the multiprocessor format is selected, the parity bit setting is invalid. All other bit settings are the same as those in normal asynchronous mode. The clock used for multiprocessor communication is the same as that in normal asynchronous mode.

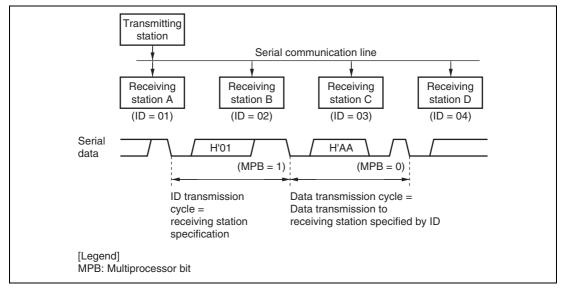

Figure 12.10 Example of Communication Using Multiprocessor Format (Transmission of Data H'AA to Receiving Station A)

## 12.5.1 Multiprocessor Serial Data Transmission

Figure 12.11 shows a sample flowchart for multiprocessor serial data transmission. For an ID transmission cycle, set the MPBT bit in SSR to 1 before transmission. For a data transmission cycle, clear the MPBT bit in SSR to 0 before transmission. All other SCI operations are the same as those in asynchronous mode.

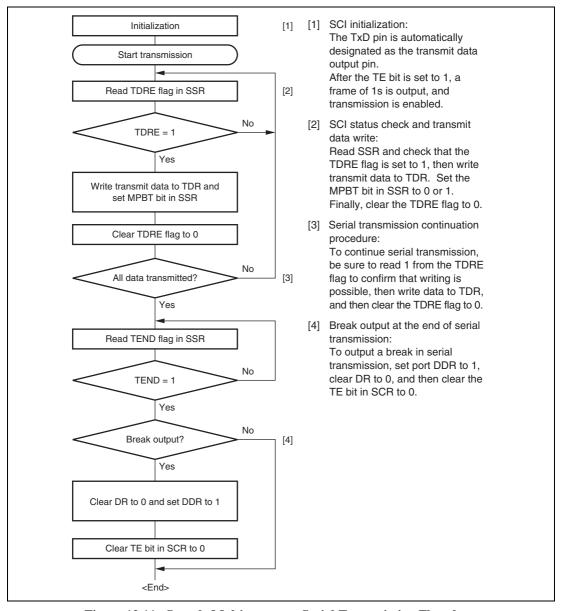

Figure 12.11 Sample Multiprocessor Serial Transmission Flowchart

## 12.5.2 Multiprocessor Serial Data Reception

Figure 12.13 shows a sample flowchart for multiprocessor serial data reception. If the MPIE bit in SCR is set to 1, data is skipped until data with a 1 multiprocessor bit is sent. On receiving data with a 1 multiprocessor bit, the receive data is transferred to RDR. An RXI interrupt request is generated at this time. All other SCI operations are the same as in asynchronous mode. Figure 12.12 shows an example of SCI operation for multiprocessor format reception.

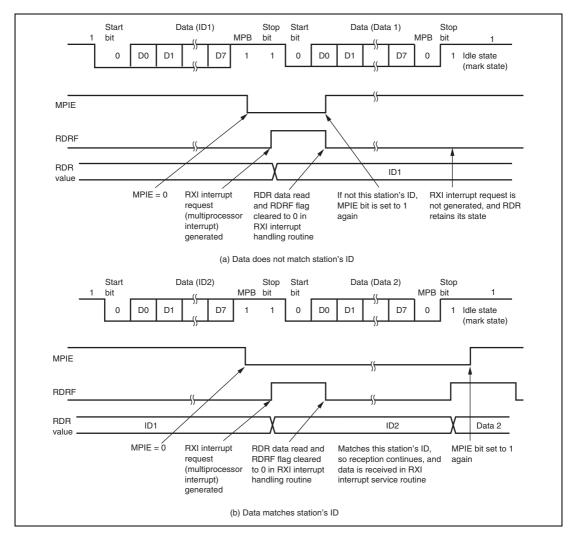

Figure 12.12 Example of SCI Receive Operation (Example with 8-Bit Data, Multiprocessor Bit, One Stop Bit)

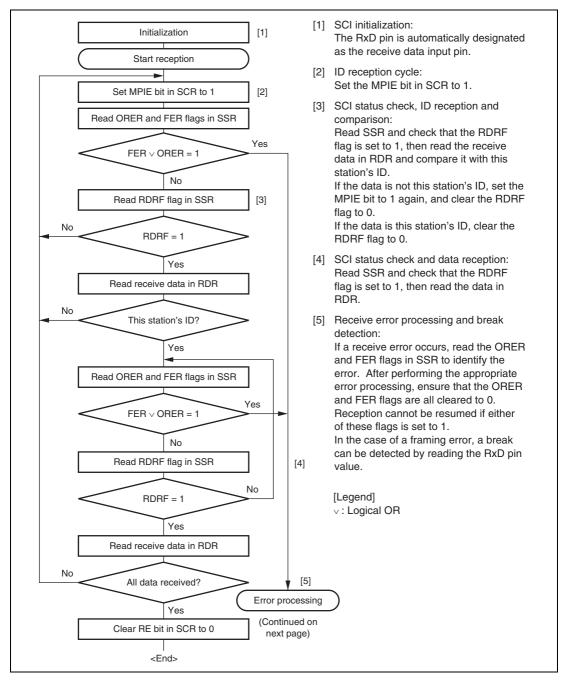

Figure 12.13 Sample Multiprocessor Serial Reception Flowchart (1)

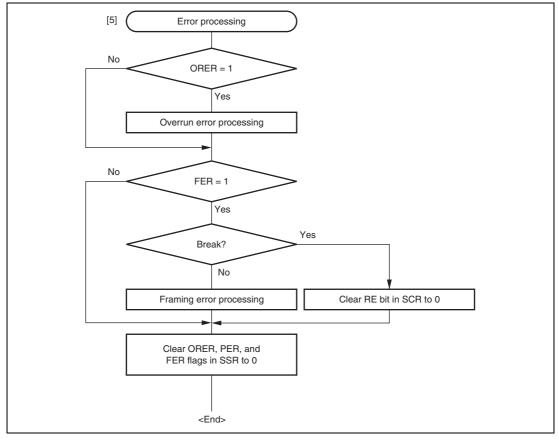

Figure 12.13 Sample Multiprocessor Serial Reception Flowchart (2)

# 12.6 Operation in Clock Synchronous Mode

Figure 12.14 shows the general format for clock synchronous communication. In clock synchronous mode, data is transmitted or received in synchronization with clock pulses. One character in transfer data consists of 8-bit data. In data transmission, the SCI outputs data from one falling edge of the synchronization clock to the next. In data reception, the SCI receives data in synchronization with the rising edge of the synchronization clock. After 8-bit data is output, the transmission line holds the MSB state. In clock synchronous mode, no parity or multiprocessor bit is added. Inside the SCI, the transmitter and receiver are independent units, enabling full-duplex communication by use of a common clock. Both the transmitter and the receiver also have a double-buffered structure, so that the next transmit data can be written during transmission or the previous receive data can be read during reception, enabling continuous data transfer.

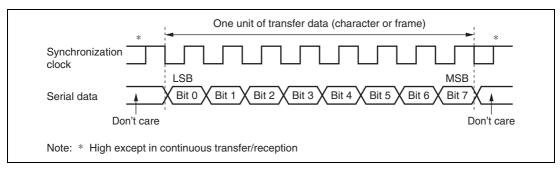

Figure 12.14 Data Format in Clock Synchronous Communication (LSB-First)

#### 12.6.1 Clock

Either an internal clock generated by the on-chip baud rate generator or an external synchronization clock input at the SCK pin can be selected, according to the setting of the CKE1 and CKE0 bits in SCR. When the SCI is operated on an internal clock, the synchronization clock is output from the SCK pin. Eight synchronization clock pulses are output in the transfer of one character, and when no transfer is performed the clock is fixed high.

#### 12.6.2 SCI Initialization (Clock Synchronous Mode)

Before transmitting and receiving data, you should first clear the TE and RE bits in SCR to 0, then initialize the SCI as described in a sample flowchart in figure 12.15. When the operating mode, transfer format, etc., is changed, the TE and RE bits must be cleared to 0 before making the change using the following procedure. When the TE bit is cleared to 0, the TDRE flag in SSR is set to 1. However, clearing the RE bit to 0 does not initialize the RDRF, PER, FER, and ORER flags in SSR, or RDR.

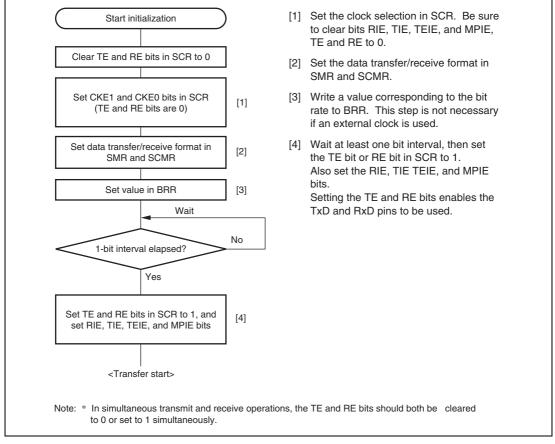

Figure 12.15 Sample SCI Initialization Flowchart

### 12.6.3 Serial Data Transmission (Clock Synchronous Mode)

Figure 12.16 shows an example of SCI operation for transmission in clock synchronous mode. In serial transmission, the SCI operates as described below.

- 1. The SCI monitors the TDRE flag in SSR, and if it is 0, recognizes that data has been written to TDR, and transfers the data from TDR to TSR.
- 2. After transferring data from TDR to TSR, the SCI sets the TDRE flag to 1 and starts transmission. If the TIE bit in SCR is set to 1 at this time, a TXI interrupt request is generated. Because the TXI interrupt routine writes the next transmit data to TDR before transmission of the current transmit data has finished, continuous transmission can be enabled.
- 3. 8-bit data is sent from the TxD pin synchronized with the output clock when output clock mode has been specified and synchronized with the input clock when use of an external clock has been specified.
- 4. The SCI checks the TDRE flag at the timing for sending the last bit.
- 5. If the TDRE flag is cleared to 0, data is transferred from TDR to TSR, and serial transmission of the next frame is started.
- 6. If the TDRE flag is set to 1, the TEND flag in SSR is set to 1, and the TxD pin maintains the output state of the last bit. If the TEIE bit in SCR is set to 1 at this time, a TEI interrupt request is generated. The SCK pin is fixed high.

Figure 12.17 shows a sample flow chart for serial data transmission. Even if the TDRE flag is cleared to 0, transmission will not start while a receive error flag (ORER, FER, or PER) is set to 1. Make sure to clear the receive error flags to 0 before starting transmission. Note that clearing the RE bit to 0 does not clear the receive error flags.

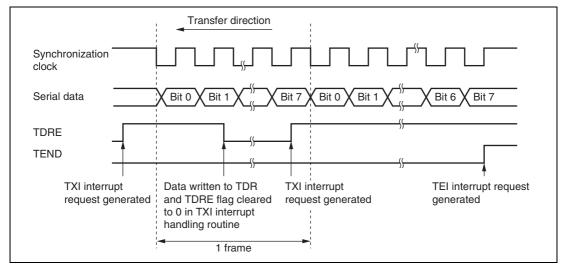

Figure 12.16 Example of SCI Transmit Operation in Clock Synchronous Mode

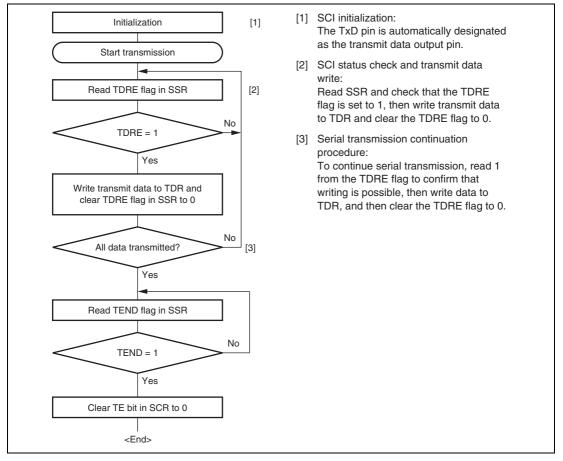

Figure 12.17 Sample Serial Transmission Flowchart

## 12.6.4 Serial Data Reception (Clock Synchronous Mode)

Figure 12.18 shows an example of SCI operation for reception in clock synchronous mode. In serial reception, the SCI operates as described below.

- 1. The SCI performs internal initialization in synchronization with a synchronization clock input or output, starts receiving data, and stores the receive data in RSR.
- 2. If an overrun error (when reception of the next data is completed while the RDRF flag is still set to 1) occurs, the ORER bit in SSR is set to 1. If the RIE bit in SCR is set to 1 at this time, an ERI interrupt request is generated. Receive data is not transferred to RDR. The RDRF flag remains to be set to 1.
- 3. If reception finishes successfully, the RDRF bit in SSR is set to 1, and receive data is transferred to RDR. If the RIE bit in SCR is set to 1 at this time, an RXI interrupt request is generated. Because the RXI interrupt routine reads the receive data transferred to RDR before reception of the next receive data has finished, continuous reception can be enabled.

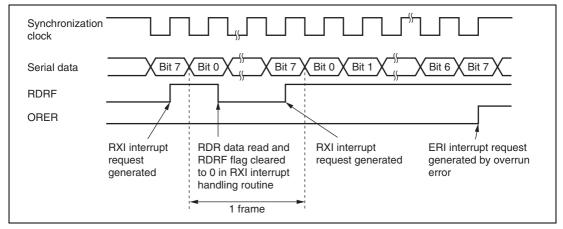

Figure 12.18 Example of SCI Receive Operation in Clock Synchronous Mode

Reception cannot be resumed while a receive error flag is set to 1. Accordingly, clear the ORER, FER, PER, and RDRF bits to 0 before resuming reception. Figure 12.19 shows a sample flowchart for serial data reception.

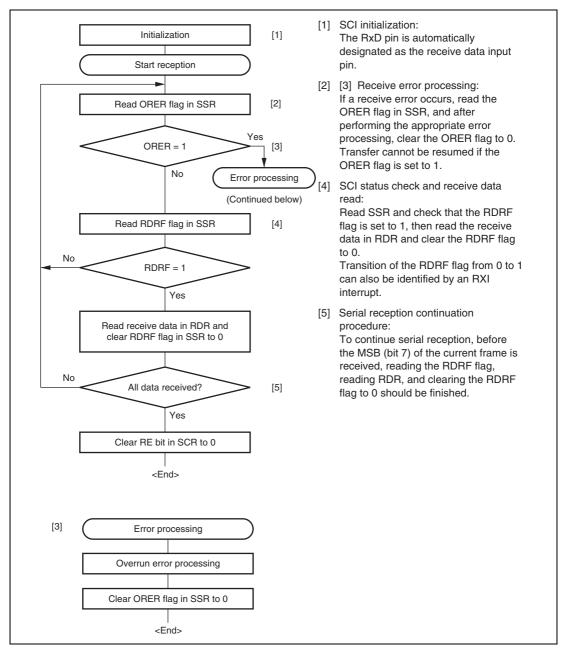

Figure 12.19 Sample Serial Reception Flowchart

## 12.6.5 Simultaneous Serial Data Transmission and Reception (Clock Synchronous Mode)

Figure 12.20 shows a sample flowchart for simultaneous serial transmit and receive operations. After initializing the SCI, the following procedure should be used for simultaneous serial data transmit and receive operations. To switch from transmit mode to simultaneous transmit and receive mode, check that the SCI has finished transmission and the TDRE and TEND flags in SSR are set to 1, clear the TE bit in SCR to 0, and then set the TE and RE bits to 1 simultaneously with a single instruction. To switch from receive mode to simultaneous transmit and receive mode, check that the SCI has finished reception, and clear the RE bit to 0. Then after checking that the RDRF bit in SSR and receive error flags (ORER, FER, and PER) are cleared to 0, set the TE and RE bits to 1 simultaneously with a single instruction.

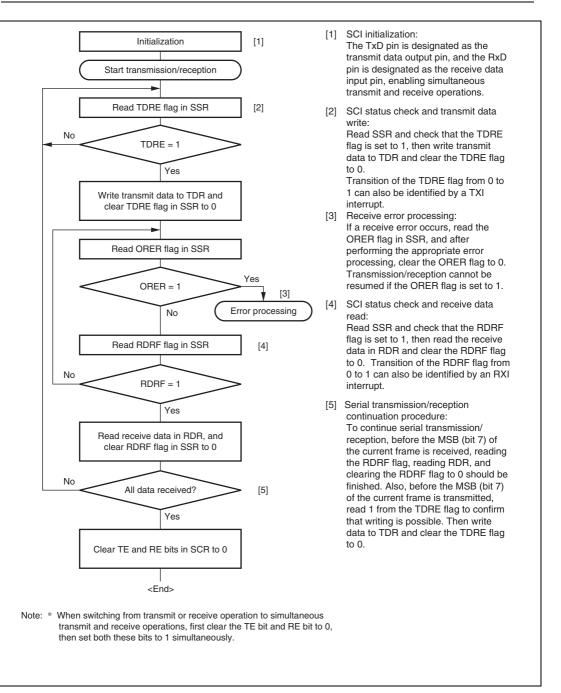

Figure 12.20 Sample Flowchart of Simultaneous Serial Transmission and Reception

# 12.7 IrDA Operation

IrDA operation can be used with SCI\_2. Figure 12.21 shows an IrDA block diagram.

If the IrDA function is enabled using the IrE bit in KBCOMP, the TxD2 and RxD2 pins in SCI\_2 are allowed to encode and decode the waveform based on the IrDA standard version 1.0 (function as the IrTxD and IrRxD pins). Connecting these pins to the infrared data transceiver achieves infrared data communication based on the system defined by the IrDA standard version 1.0.

In the system defined by the IrDA standard version 1.0, communication is started at a transfer rate of 9600 bps, which can be modified as required. The IrDA interface provided by this LSI does not incorporate the capability of automatic modification of the transfer rate; the transfer rate must be modified through programming.

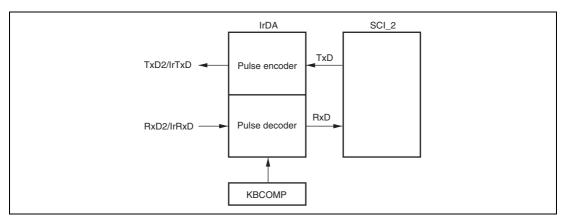

Figure 12.21 IrDA Block Diagram

**Transmission:** During transmission, the output signals from the SCI (UART frames) are converted to IR frames using the IrDA interface (see figure 12.22).

For serial data of level 0, a high-level pulse having a width of 3/16 of the bit rate (1-bit interval) is output (initial setting). The high-level pulse can be selected using the IrCKS2 to IrCKS0 bits in KBCOMP.

The high-level pulse width is defined to be 1.41  $\mu$ s at minimum and  $(3/16 + 2.5\%) \times$  bit rate or  $(3/16 \times \text{bit rate}) + 1.08 \,\mu$ s at maximum. For example, when the frequency of system clock  $\phi$  is 20 MHz, a high-level pulse width of at least 1.4  $\mu$ s to 1.6  $\mu$ s can be specified.

For serial data of level 1, no pulses are output.

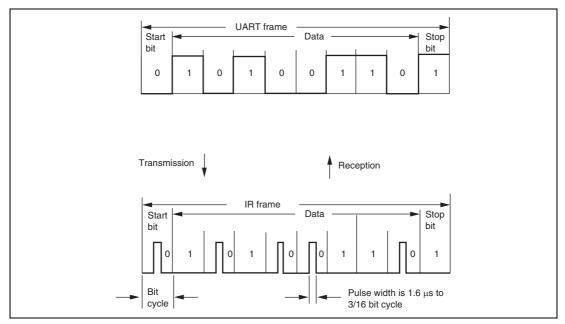

Figure 12.22 IrDA Transmission and Reception

**Reception:** During reception, IR frames are converted to UART frames using the IrDA interface before inputting to SCI\_2.

Data of level 0 is output each time a high-level pulse is detected and data of level 1 is output when no pulse is detected in a bit cycle. If a pulse has a high-level width of less than 1.41  $\mu$ s, the minimum width allowed, the pulse is recognized as level 0.

**High-Level Pulse Width Selection:** Table 12.10 shows possible settings for bits IrCKS2 to IrCKS0 (minimum pulse width), and this LSI's operating frequencies and bit rates, for making the pulse width shorter than 3/16 times the bit rate in transmission.

Table 12.10 IrCKS2 to IrCKS0 Bit Settings

Operating	Bit Rate (bps) (Upper Row) / Bit Interval × 3/16 (μs) (Lower Row)						
Frequency	2400	9600	19200	38400	57600	115200	
φ (MHz)	78.13	19.53	9.77	4.88	3.26	1.63	
2	010	010	010	010	010	_	
2.097152	010	010	010	010	010	_

20	101	101	101	101	101	101	

[Legend]

—: An SCI bit rate setting cannot be made.

# 12.8 Interrupt Sources

Table 12.11 shows the interrupt sources in serial communication interface. A different interrupt vector is assigned to each interrupt source, and individual interrupt sources can be enabled or disabled using the enable bits in SCR.

When the TDRE flag in SSR is set to 1, a TXI interrupt request is generated. When the TEND flag in SSR is set to 1, a TEI interrupt request is generated.

When the RDRF flag in SSR is set to 1, an RXI interrupt request is generated. When the ORER, PER, or FER flag in SSR is set to 1, an ERI interrupt request is generated.

A TEI interrupt is requested when the TEND flag is set to 1 while the TEIE bit is set to 1. If a TEI interrupt and a TXI interrupt are requested simultaneously, the TXI interrupt has priority for acceptance. However, note that if the TDRE and TEND flags are cleared simultaneously by the TXI interrupt routine, the SCI cannot branch to the TEI interrupt routine later.

**Table 12.11 SCI Interrupt Sources** 

Channel	Name	Interrupt Source	Interrupt Flag	Priority
0	ERI0	Receive error	ORER, FER, PER	High
	RXI0	Receive data full	RDRF	
	TXI0	Transmit data empty	TDRE	
	TEI0	Transmit end	TEND	_
1	ERI1	Receive error	ORER, FER, PER	_
	RXI1	Receive data full	RDRF	
	TXI1	Transmit data empty	TDRE	_
	TEI1	Transmit end	TEND	_
2	ERI2	Receive error	ORER, FER, PER	_
	RXI2	Receive data full	RDRF	_
	TXI2	Transmit data empty	TDRE	_
	TEI2	Transmit end	TEND	Low

# 12.9 Usage Notes

### 12.9.1 Module Stop Mode Setting

SCI operation can be disabled or enabled using the module stop control register. The initial setting is for SCI operation to be halted. Register access is enabled by clearing module stop mode. For details, refer to section 18, Power-Down Modes.

### 12.9.2 Break Detection and Processing

When framing error detection is performed, a break can be detected by reading the RxD pin value directly. In a break, the input from the RxD pin becomes all 0s, and so the FER flag in SSR is set, and the PER flag may also be set. Note that, since the SCI continues the receive operation even after receiving a break, even if the FER flag is cleared to 0, it will be set to 1 again.

#### 12.9.3 Mark State and Break Detection

When the TE bit in SCR is 0, the TxD pin is used as an I/O port whose direction (input or output) and level are determined by DR and DDR of the port. This can be used to set the TxD pin to the mark state (high level) or send a break during serial data transmission. To maintain the communication line at mark state until TE is set to 1, set both DDR and DR to 1. Since the TE bit is cleared to 0 at this point, the TxD pin becomes an I/O port, and 1 is output from the TxD pin. To send a break during serial transmission, first set DDR to 1 and DR to 0, and then clear the TE bit to 0. When the TE bit is cleared to 0, the transmitter is initialized regardless of the current transmission state, the TxD pin becomes an I/O port, and 0 is output from the TxD pin.

# 12.9.4 Receive Error Flags and Transmit Operations (Clock Synchronous Mode Only)

Transmission cannot be started when a receive error flag (ORER, FER, or RER) is SSR is set to 1, even if the TDRE flag in SSR is cleared to 0. Be sure to clear the receive error flags to 0 before starting transmission. Note also that the receive error flags cannot be cleared to 0 even if the RE bit in SCR is cleared to 0.

# 12.9.5 Relation between Writing to TDR and TDRE Flag

Data can be written to TDR irrespective of the TDRE flag status in SSR. However, if the new data is written to TDR when the TDRE flag is 0, that is, when the previous data has not been transferred to TSR yet, the previous data in TDR is lost. Be sure to write transmit data to TDR after verifying that the TDRE flag is set to 1.

## 12.9.6 SCI Operations during Mode Transitions

**Transmission:** Before making a transition to module stop, software standby, or sub-sleep mode, stop all transmit operations (TE = TIE = TEIE = 0). TSR, TDR, and SSR are reset. The states of the output pins during each mode depend on the port settings, and the pins output a high-level signal after mode cancellation. If a transition is made during data transmission, the data being transmitted will be undefined.

To transmit data in the same transmission mode after mode cancellation, set TE to 1, read SSR, write to TDR, clear TDRE in this order, and then start transmission. To transmit data in a different transmission mode, initialize the SCI first.

Figure 12.23 shows a sample flowchart for mode transition during transmission. Figures 12.24 and 12.25 show the pin states during transmission.

**Reception:** Before making a transition to module stop, software standby, watch, sub-active, or sub-sleep mode, stop reception (RE = 0). RSR, RDR, and SSR are reset. If a transition is made during data reception, the data being received will be invalid.

To receive data in the same reception mode after mode cancellation, set RE to 1, and then start reception. To receive data in a different reception mode, initialize the SCI first.

Figure 12.27 shows a sample flowchart for mode transition during reception.

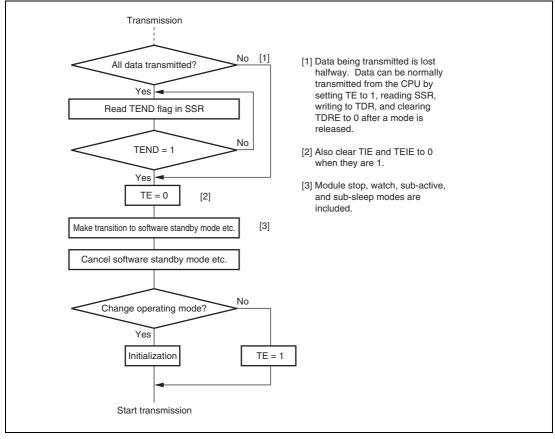

Figure 12.23 Sample Flowchart for Mode Transition during Transmission

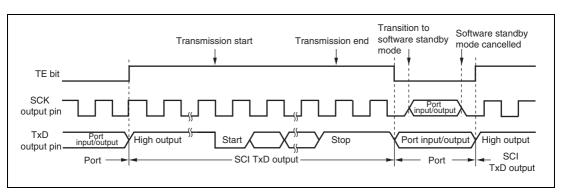

Figure 12.24 Pin States during Transmission in Asynchronous Mode (Internal Clock)

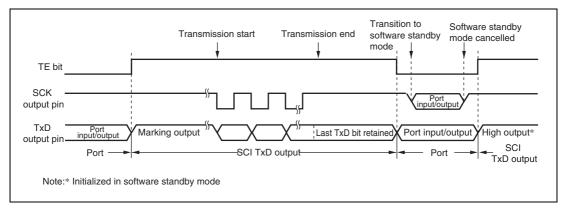

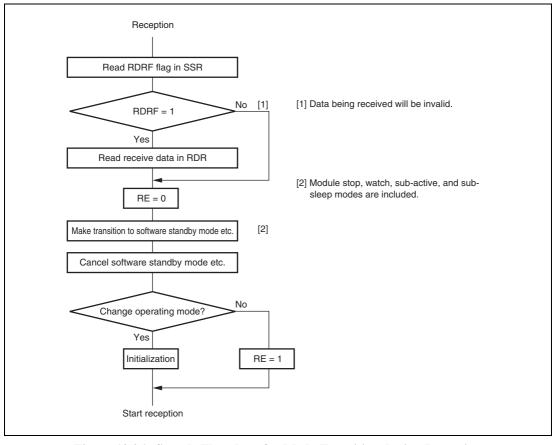

Figure 12.25 Pin States during Transmission in Clock Synchronous Mode (Internal Clock)

 $Figure\ 12.26\quad Sample\ Flowchart\ for\ Mode\ Transition\ during\ Reception$ 

## 12.9.7 Notes on Switching from SCK Pins to Port Pins

When SCK pins are switched to port pins after transmission has completed, pins are enabled for port output after outputting a low pulse of half a cycle as shown in figure 12.28.

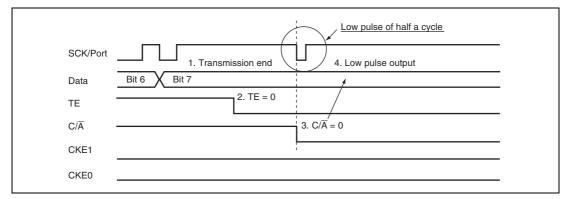

Figure 12.27 Switching from SCK Pins to Port Pins

To prevent the low pulse output that is generated when switching the SCK pins to the port pins, specify the SCK pins for input (pull up the SCK/port pins externally), and follow the procedure below with DDR = 1, DR = 1,  $C/\overline{A}$  = 1, CKE1 = 0, CKE1 = 0, and TE = 1.

- 1. End serial data transmission
- 2. TE bit = 0
- 3. CKE1 bit = 1
- 4.  $C/\overline{A}$  bit = 0 (switch to port output)
- 5. CKE1 bit = 0

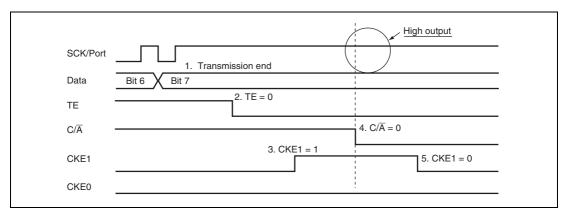

Figure 12.28 Prevention of Low Pulse Output at Switching from SCK Pins to Port Pins

# Section 13 D/A Converter

#### 13.1 **Features**

- 8-bit resolution
- Two output channels
- Conversion time: Max. 10 µs (when load capacitance is 20 pF)
- Output voltage: 0 V to AVref for the H8S/2144B and 0 V to AVcc for the H8S/2134B
- D/A output retaining function in software standby mode

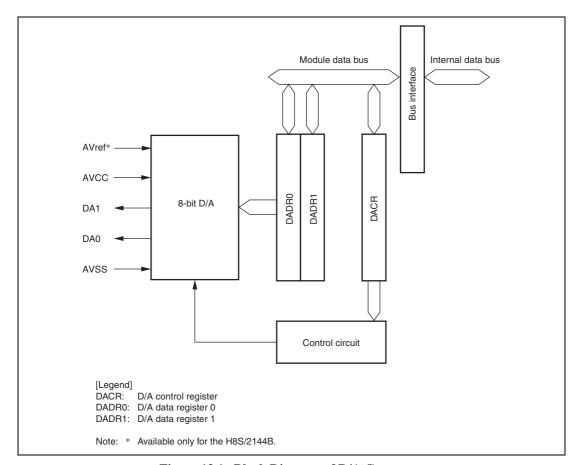

Figure 13.1 Block Diagram of D/A Converter

### 13.2 Input/Output Pins

Table 13.1 summarizes the input/output pins used by the D/A converter.

**Table 13.1 Pin Configuration** 

Pin Name	Symbol	I/O	Function
Analog power supply pin	AVCC	Input	Analog block power supply
Analog ground pin	AVSS	Input	Analog block ground and reference voltage
Analog output pin 0	DA0	Output	Channel 0 analog output
Analog output pin 1	DA1	Output	Channel 1 analog output
Reference power supply pin	AVref*	Input	Analog block reference voltage

Note: \* Available only for the H8S/2144B.

# 13.3 Register Descriptions

The D/A converter has the following registers.

- D/A data register 0 (DADR0)
- D/A data register 1 (DADR1)
- D/A control register (DACR)

### 13.3.1 D/A Data Registers 0 and 1 (DADR0, DADR1)

DADR0 and DADR1 are 8-bit readable/writable registers that store data for D/A conversion. When analog output is permitted, D/A data register contents are converted and output to analog output pins. DADR0 and DADR1 are initialized to H'00.

# 13.3.2 D/A Control Register (DACR)

DACR controls D/A converter operation.

Bit	Bit Name	Initial Value	R/W	Description
7	DAOE1	0	R/W	D/A Output Enable 1
				Controls D/A conversion and analog output.
				0: Analog output DA1 is disabled
				1: D/A conversion for channel 1 and analog output DA1 are enabled
6	DAOE0	0	R/W	D/A Output Enable 0
				Controls D/A conversion and analog output.
				0: Analog output DA0 is disabled
				1: D/A conversion for channel 0 and analog output DA0 are enabled
5	DAE	0	R/W	D/A Enable
				Controls D/A conversion in conjunction with the DAOE0 and DAOE1 bits. When the DAE bit is cleared to 0, D/A conversion for channels 0 and 1 is controlled individually. When the DAE bit is set to 1, D/A conversion for channels 0 and 1 are controlled as one. Conversion result output is controlled by the DAOE0 and DAOE1 bits. For details, see table 13.2 below.
4	_	All 1	R	Reserved
to 0				These bits are always read as 1 and cannot be modified.

Table 13.2 D/A Channel Enable

Bit 7	Bit 6	Bit 5	
DAOE1	DAOE0	DAE	Description
0	0	_	Disables D/A conversion
	1	0	Enables D/A conversion for channel 0
			Disables D/A conversion for channel 1
		1	Enables D/A conversion for channels 0 and 1
1	0	0	Disables D/A conversion for channel 0
			Enables D/A conversion for channel 1
		1	Enables D/A conversion for channels 0 and 1
	1	_	Enables D/A conversion for channels 0 and 1

### 13.4 Operation

The D/A converter incorporates two channels of the D/A circuits and can be converted individually.

When the DAOE bit in DACR is set to 1, D/A conversion is enabled and conversion results are output.

An example of D/A conversion of channel 0 is shown below. The operation timing is shown in figure 13.2.

- 1. Write conversion data to DADRO.
- 2. When the DAOE0 bit in DACR is set to 1, D/A conversion starts. After the interval of t<sub>DCONV</sub>, conversion results are output from the analog output pin DA0. The conversion results are output continuously until DADR0 is modified or the DAOE0 bit is cleared to 0. The output value is calculated by the following formula:

DADR contents/256 × AVref

- Conversion starts immediately after DADR0 is modified. After the interval of t<sub>DCONV</sub>, conversion results are output.
- 4. When the DAOE0 bit is cleared to 0, analog output is disabled.

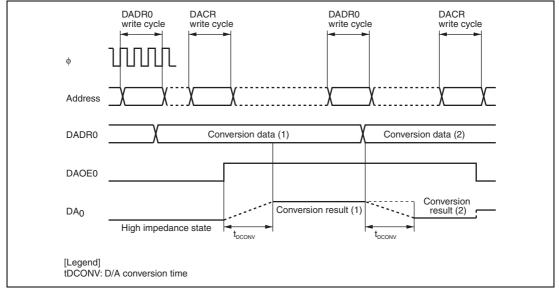

Figure 13.2 D/A Converter Operation Example

### 13.5 Usage Note

When this LSI enters software standby mode with D/A conversion enabled, the D/A output is retained, and the analog power supply current is equal to as during D/A conversion. If the analog power supply current needs to be reduced in software standby mode, clear the DAOE1, DAOE0, and DAE bits all to 0 to disable D/A output.

### 13.5.1 Module Stop Mode Setting

D/A converter operation can be enabled or disabled using the module stop control register. The initial setting is for D/A converter operation to be halted. Register access is enabled by canceling module stop mode. For details, refer to section 18, Power-Down Modes.

# Section 14 A/D Converter

This LSI includes a 10-bit successive-approximation-type A/D converter that allows up to eight analog input channels and up to 16 digital input channels\* to be selected. A/D conversion for digital input is effective as a comparator in multiple input testing.

Note: \* Up to eight channels in the H8S/2134B

#### 14.1 Features

- 10-bit resolution
- Input channels: eight analog input channels and 16 digital input channels\*<sup>1</sup>
- Analog conversion voltage range can be specified using the reference power supply voltage pin (AVref\*<sup>2</sup>) as an analog reference voltage.
- Conversion time: 13.4 µs per channel (at 10-MHz operation)
- Two kinds of operating modes
  - Single mode: Single-channel A/D conversion
  - Scan mode: Continuous A/D conversion on 1 to 4 channels
- Four data registers
  - Conversion results are held in a 16-bit data register for each channel
- Sample and hold function
- Three kinds of conversion start
  - Software, 8-bit timer (TMR) conversion start trigger, or external trigger signal.
- Interrupt request
  - A/D conversion end interrupt (ADI) request can be generated

Notes: 1. Up to eight channels in the H8S/2134B

2. Available only for the H8S/2144B.

A block diagram of the A/D converter is shown in figure 14.1.

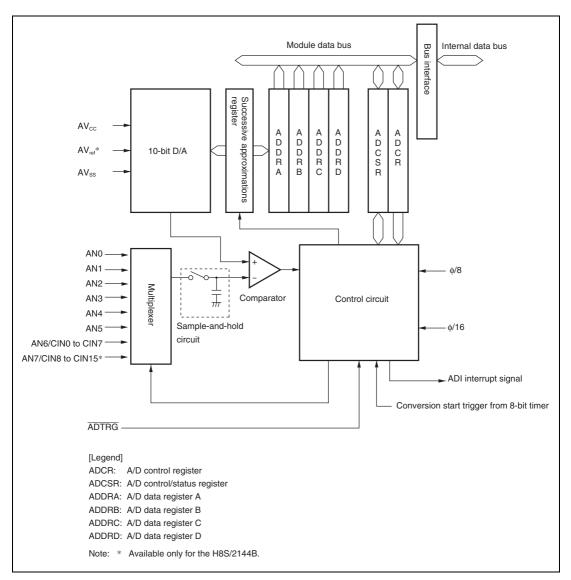

Figure 14.1 Block Diagram of A/D Converter

### 14.2 Input/Output Pins

Table 14.1 summarizes the pins used by the A/D converter. The 8 analog input pins are divided into two groups consisting of four channels. Analog input pins 0 to 3 (AN0 to AN3) comprising group 0 and analog input pins 4 to 7 (AN4 to AN7) comprising group 1. Expanded A/D conversion input pins (CIN0 to CIN15) can be selected with the AN6 and AN7 pins. The AVcc and AVss pins are the power supply pins for the analog block in the A/D converter.

**Table 14.1 Pin Configuration** 

Pin Name	Symbol	I/O	Function
Analog power supply pin	AV <sub>cc</sub>	Input	Analog block power supply and reference voltage
Analog ground pin	AV <sub>ss</sub>	Input	Analog block ground and reference voltage
Reference power supply pin	AVref	Input	Reference voltage for A/D conversion (Available only for the H8S/2144B.)
Analog input pin 0	AN0	Input	Group 0 analog input pins
Analog input pin 1	AN1	Input	
Analog input pin 2	AN2	Input	
Analog input pin 3	AN3	Input	
Analog input pin 4	AN4	Input	Group 1 analog input pins
Analog input pin 5	AN5	Input	
Analog input pin 6	AN6	Input	
Analog input pin 7	AN7	Input	
A/D external trigger input pin	ADTRG	Input	External trigger input pin for starting A/D conversion
Expanded A/D conversion input pins 0 to 15	CIN0 to CIN15	Input	Expanded A/D conversion input (digital input) channels 0 to 15. Can be used as digital input pins. Channels 0 to 7 are available for the H8S/2134B.

### 14.3 Register Descriptions

The A/D converter has the following registers.

- A/D data register A (ADDRA)
- A/D data register B (ADDRB)
- A/D data register C (ADDRC)
- A/D data register D (ADDRD)
- A/D control/status register (ADCSR)
- A/D control register (ADCR)
- Keyboard comparator control register (KBCOMP)

#### 14.3.1 A/D Data Registers A to D (ADDRA to ADDRD)

There are four 16-bit read-only ADDR registers, ADDRA to ADDRD, used to store the results of A/D conversion. The ADDR registers, which store a conversion result for each channel, are shown in table 14.2.

The converted 10-bit data is stored to bits 15 to 6. The lower 6-bit data is always read as 0.

The data bus between the CPU and the A/D converter is 8-bit width. The upper byte can be read directly from the CPU, but the lower byte should be read via a temporary register. The temporary register contents are transferred from the ADDR when the upper byte data is read. When reading the ADDR, read the upper byte before lower byte or in word units.

Table 14.2 Analog Input Channels and Corresponding ADDR Registers

	Analog Input Channel	A/D Data Register to Store A/D Conversion	
Group 0	Group 1	Results	
AN0	AN4	ADDRA	
An1	AN5	ADDRB	
AN2	AN6, or CIN0 to CIN7	ADDRC	
AN3	AN7, or CIN8 to CIN15*	ADDRD	

Note: \* Available only for the H8S/2144B.

# 14.3.2 A/D Control/Status Register (ADCSR)

ADCSR controls A/D conversion operations.

Bit	Bit Name	Initial Value	R/W	Description
7	ADF	0	R/(W)*1	A/D End Flag
				A status flag that indicates the end of A/D conversion.
				[Setting conditions]
				When A/D conversion ends in single mode
				When A/D conversion ends on all channels
				specified in scan mode
				[Clearing conditions]
				<ul> <li>When 0 is written after reading ADF = 1</li> </ul>
6	ADIE	0	R/W	A/D Interrupt Enable
				Enables ADI interrupt by ADF when this bit is set to 1
5	ADST	0	R/W	A/D Start
				Setting this bit to 1 starts A/D conversion. Clearing this bit to 0 stops A/D conversion. In single mode, this bit is cleared to 0 automatically when conversion on the specified channel ends. In scan mode, conversion continues sequentially on the specified channels until this bit is cleared to 0 by software, a reset, or a transition to standby mode or module stop mode.
4	SCAN	0	R/W	Scan Mode
				Selects the A/D conversion operating mode. The setting of this bit must be made when conversion is halted (ADST = 0).
				0: Single mode
				1: Scan mode
3	CKS	0	R/W	Clock Select
				Sets A/D conversion time. The input channel setting must be made when conversion is halted (ADST = 0).
				0: Conversion time is 266 states (max)
				1: Conversion time is 134 states (max)
				Switch conversion time while ADST is 0.

Bit	Bit Name	Initial Value	R/W	Description	
2	CH2	0	R/W	R/W Channel Select 2 to 0	
1	CH1	0	R/W	Select analog input channel	•
0	CH0	0	R/W	N setting must be made when conversion is half $(ADST = 0)$ .	
				When SCAN = 0:	When SCAN = 1:
				000: AN0	000: AN0
				001: AN1	001: AN0 and AN1
				010: AN2	010: AN0 to AN2
				011: AN3	011: AN0 to AN3
				100: AN4	100: AN4
				101: AN5	101: AN4 and AN5
				110: AN6, or CIN0 to CIN7	110: AN4 to AN6 or
				111: AN7, or CIN8 to	CIN0 to CIN7
				CIN15* <sup>2</sup>	111: AN4 to AN6 or CIN0 to CIN7, or AN7 or CIN8 to CIN15*2

Notes: 1. Only 0 can be written for clearing the flag.

2. CIN8 to CIN15 are available only for the H8S/2144B.

# 14.3.3 A/D Control Register (ADCR)

ADCR enables A/D conversion started by an external trigger signal.

Bit	Bit Name	Initial Value	R/W	Description
7	TRGS1	0	R/W	Timer Trigger Select 1 and 0
6	TRGS0	0	R/W	Enable the start of A/D conversion by a trigger signal. Only set bits TRGS1 and TRGS0 when conversion is halted (ADST = 0).
				00: A/D conversion start by external trigger is disabled
				01: A/D conversion start by external trigger is disabled
				<ol> <li>A/D conversion start by conversion trigger from TMR is enabled</li> </ol>
				11: A/D conversion start by ADTRG pin is enabled
5	_	All 1	R	Reserved
to 0				These bits are always read as 1 and cannot be modified.

### 14.3.4 Keyboard Comparator Control Register (KBCOMP)

KBCOMP selects the CIN input channel for which A/D conversion is performed and enables or disables the comparator scan function of CIN15 to CIN0.

Bit	Bit Name	Initial Value	R/W	Description	
7	IrE	0	R/W	These bits are related to the SCI. For details, refer to section 12.3.10, Keyboard Comparator Control Register (KBCOMP).	
6	IrCKS2	0	R/W		
5	IrCKS1	0	R/W	= riegister (RECOIVIII ).	
4	IrCKS0	0	R/W	_	
3	KBADE	0	R/W	Keyboard A/D Enable (AN	N6, AN7)
				Selects whether channels 6 and 7 of the A/D converter are used as analog pins or digital pins, in combination with the KBCH2 to KBCH0 bits. For details, refer to description for bits 2 to 0. Analog pins of the A/D converter are set to digital pins (CIN0 to CIN7 and CIN8 to CIN15*).	
2	KBCH2	0	R/W	Keyboard A/D Channel Select 2 to 0	
1	KBCH1	0	R/W	These bits select a channel of digital input pins for A/E conversion, in combination with the KBADE bit. The input channel setting must be made while conversion halted.	
0	KBCH0	0	R/W		
				Channel 6	Channel 7
				0xxx: Selects AN6	AN7
				1000: Selects CIN0	CIN8*
				1001: Selects CIN1	CIN9*
				1010: Selects CIN2	CIN10*
				1011: Selects CIN3	CIN11*
				1100: Selects CIN4	CIN12*
				1101: Selects CIN5	CIN13*
				1110: Selects CIN6	CIN14*
				1111: Selects CIN7	CIN15*

[Legend]

x: Don't care

Note: \* CIN8 to CIN15 are available only for the H8S/2144B.

### 14.4 Operation

The A/D converter operates by successive approximation with 10-bit resolution. It has two operating modes: single mode and scan mode. When changing the operating mode or analog input channel, to prevent incorrect operation, first clear the ADST bit to 0 in ADCSR to halt A/D conversion. The ADST bit can be set at the same time as the operating mode or analog input channel is changed.

#### 14.4.1 Single Mode

In single mode, A/D conversion is to be performed only once on the specified single channel. Operations are as follows.

- 1. A/D conversion on the specified channel is started when the ADST bit in ADCSR is set to 1, by software or an external trigger input.
- 2. When A/D conversion is completed, the result is transferred to the A/D data register corresponding to the channel.
- 3. On completion of A/D conversion, the ADF bit in ADCSR is set to 1. If the ADIE bit is set to 1 at this time, an ADI interrupt request is generated.
- 4. The ADST bit remains set to 1 during A/D conversion. When conversion ends, the ADST bit is automatically cleared to 0, and the A/D converter enters wait state.

#### **14.4.2** Scan Mode

Scan mode is useful for monitoring analog inputs in a group of one or more channels. When the ADST bit is set to 1 by software, or by timer or external trigger input, A/D conversion starts on the first channel in the group (AN0 when CH2 = 0; AN4 when CH2 = 1).

When two or more channels are selected, after conversion of the first channel ends, conversion of the second channel (AN1 or AN5) starts immediately. A/D conversion continues cyclically on the selected channels until the ADST bit is cleared to 0. The conversion results are transferred for storage into the ADDR registers corresponding to the channels.

Typical operations when three channels (AN0 to AN2) are selected in scan mode are described below.

#### Figure 14.2 shows the operation timing.

- 1. Scan mode is selected (SCAN = 1), scan group 0 is selected (CH2 = 0), analog input channels AN0 to AN2 are selected (CH1 = 1, CH0 = 0), and A/D conversion is started (ADST = 1).
- 2. When A/D conversion of the first channel (AN0) is completed, the result is transferred to ADDRA. Next, conversion of the second channel (AN1) starts automatically.
- 3. Conversion proceeds in the same way through the third channel (AN2).
- 4. When conversion of all the selected channels (AN0 to AN2) is completed, the ADF flag is set to 1 and conversion of the first channel (AN0) starts again. If the ADIE bit is set to 1 at this time, an ADI interrupt is requested after A/D conversion ends.
- 5. Steps 2 to 4 are repeated as long as the ADST bit remains set to 1. When the ADST bit is cleared to 0, A/D conversion stops. After that, if the ADST bit is set to 1, A/D conversion starts again from the first channel (AN0).

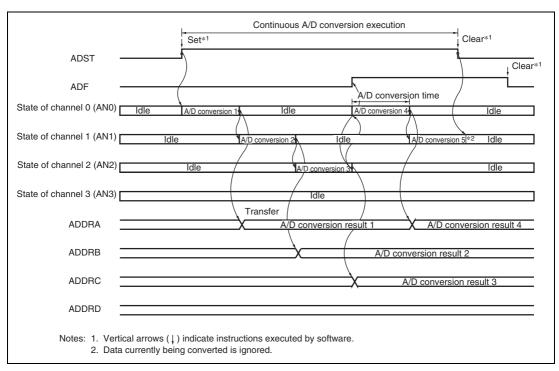

Figure 14.2 Example of A/D Converter Operation (Scan Mode, Channels AN0 to AN2 Selected)

#### 14.4.3 Input Sampling and A/D Conversion Time

The A/D converter has a built-in sample-and-hold circuit. The A/D converter samples the analog input when the A/D conversion start delay time ( $t_D$ ) passes after the ADST bit in ADCSR is set to 1, then starts A/D conversion. Figure 14.3 shows the A/D conversion timing. Table 14.3 indicates the A/D conversion time.

As indicated in figure 14.3, the A/D conversion time  $(t_{CONV})$  includes  $t_D$  and the input sampling time  $(t_{SPL})$ . The length of  $t_D$  varies depending on the timing of the write access to ADCSR. The total conversion time therefore varies within the ranges indicated in table 14.3.

In scan mode, the values given in table 14.3 apply to the first conversion time. In the second and subsequent conversions, the conversion time is 256 state (fixed) when CKS = 0 and 128 states (fixed) when CKS = 1.

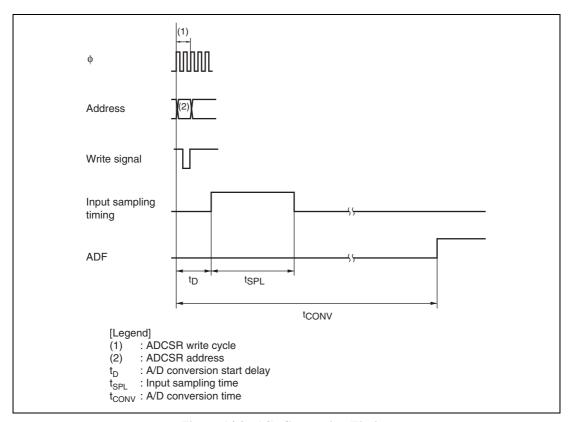

Figure 14.3 A/D Conversion Timing

**Table 14.3** A/D Conversion Time (Single Mode)

			CKS =	0		CKS =	1
Item	Symbol	Min.	Тур.	Max.	Min.	Тур.	Max.
A/D conversion start delay time	t <sub>D</sub>	10	_	17	6	_	9
Input sampling time	t <sub>SPL</sub>	_	63	_	_	31	_
A/D conversion time	t <sub>conv</sub>	259	_	266	131	_	134

Note: \* Values in the table indicate the number of states.

#### 14.4.4 External Trigger Input Timing

A/D conversion can be externally triggered. When the TRGS1 and TRGS0 bits are set to B'11 in ADCR, external trigger input is enabled at the ADTRG pin. A falling edge at the ADTRG pin sets the ADST bit to 1 in ADCSR, starting A/D conversion. Other operations, in both single and scan modes, are the same as when the ADST bit has been set to 1 by software. Figure 14.4 shows the timing.

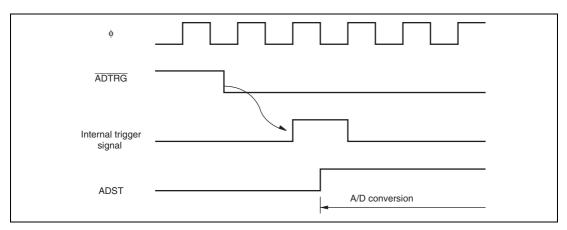

Figure 14.4 External Trigger Input Timing

# 14.5 Interrupt Sources

The A/D converter generates an A/D conversion end interrupt (ADI) at the end of A/D conversion. Setting the ADIE bit to 1 enables ADI interrupt requests while the ADF bit in ADCSR is set to 1 after A/D conversion is completed.

### 14.6 A/D Conversion Accuracy Definitions

This LSI's A/D conversion accuracy definitions are given below.

Resolution

The number of A/D converter digital output codes

Quantization error

The deviation inherent in the A/D converter, given by 1/2 LSB (see figure 14.5).

Offset error

The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from the minimum voltage value B'0000000000 (H'000) to B'0000000001 (H'001) (see figure 14.6).

Full-scale error

The deviation of the analog input voltage value from the ideal A/D conversion characteristic when the digital output changes from B'1111111110 (H'3FE) to B'1111111111 (H'3FF) (see figure 14.6).

• Nonlinearity error

The error with respect to the ideal A/D conversion characteristics between the zero voltage and the full-scale voltage. Does not include the offset error, full-scale error, or quantization error (see figure 14.6).

Absolute accuracy

The deviation between the digital value and the analog input value. Includes the offset error, full-scale error, quantization error, and nonlinearity error.

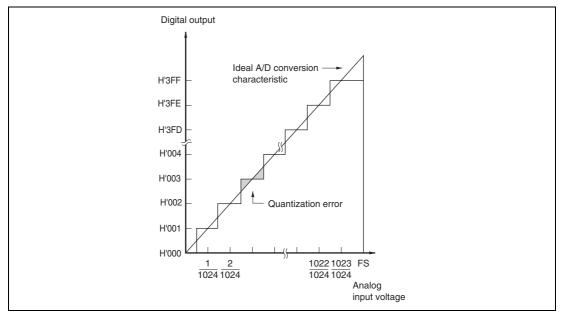

Figure 14.5 A/D Conversion Accuracy Definitions

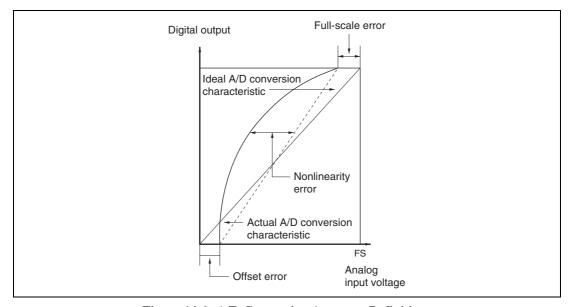

Figure 14.6 A/D Conversion Accuracy Definitions

### 14.7 Usage Notes

#### 14.7.1 Permissible Signal Source Impedance

Analog inputs of this LSI are designed so that the conversion accuracy is guaranteed for an input signal for which the signal source impedance is  $5~k\Omega$  or less. This specification is provided to enable the A/D converter's sample-and-hold circuit input capacitance to be charged within the sampling time; if the sensor output impedance exceeds  $5~k\Omega$ , charging may be insufficient and it may not be possible to guarantee the A/D conversion accuracy. However, if a large capacitance is provided externally in single mode, the input load will essentially comprise only the internal input resistance of  $10~k\Omega$ , and the signal source impedance is ignored. However, since a low-pass filter effect is obtained in this case, it may not be possible to follow an analog signal with a large differential coefficient (e.g., voltage fluctuation ratio of  $5~mV/\mu s$  or greater) (see figure 14.7). When converting a high-speed analog signal or converting in scan mode, a low-impedance buffer should be inserted. For details on the 5-V version, refer to section 20, Electrical Characteristics.

#### 14.7.2 Influences on Absolute Accuracy

Adding capacitance results in coupling with ground, and therefore noise in ground may adversely affect the absolute accuracy. Be sure to make the connection to an electrically stable ground such as AVss.

Care is also required to insure that filter circuits do not communicate with digital signals on the mounting board, so acting as antennas.

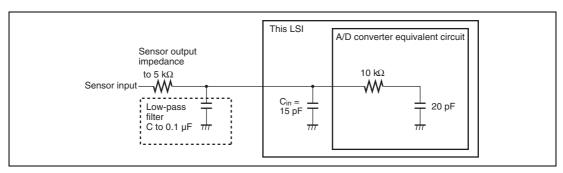

Figure 14.7 Example of Analog Input Circuit

#### 14.7.3 Setting Range of Analog Power Supply and Other Pins

If conditions shown below are not met, the reliability of this LSI may be adversely affected.

• Analog input voltage range

The voltage applied to analog input pin ANn during A/D conversion should be in the following range.

- AVss  $\leq$  ANn  $\leq$  AVref\* for the H8S/2144B (n = 0 to 7)
  - Note: \* AVref is available only for the H8S/2144B.
- AVss  $\leq$  ANn  $\leq$  AVcc for the H8S/2134B (n = 0 to 7).
- Digital input voltage range

The voltage applied to digital input pin CINn should be in the following range.

- AVss  $\leq$  CINn  $\leq$  AVref\* and Vss  $\leq$  CINn  $\leq$  Vcc for the H8S/2144B (n = 0 to 15) Note: \* AVref is available only for the H8S/2144B.
- AVss  $\leq$  CINn  $\leq$  AVcc and Vss  $\leq$  CINn  $\leq$  Vcc for the H8S/2134B (n = 0 to 7)
- Relation between AVcc, AVss and Vcc, Vss

For the relationship between AVcc, AVss and Vcc, Vss, set AVss = Vss. If the A/D converter is not used, the AVcc and AVss pins must on no account be left open.

AVref\* pin reference voltage specification range

The reference voltage of the AVref\* pin should be in the range AVref\* ≤ AVcc.

Note: \* AVref is available only for the H8S/2144B.

### 14.7.4 Notes on Board Design

In board design, digital circuitry and analog circuitry should be as mutually isolated as possible, and layout in which digital circuit signal lines and analog circuit signal lines cross or are in close proximity should be avoided as far as possible. Failure to do so may result in incorrect operation of the analog circuitry due to inductance, adversely affecting A/D conversion values. Also, digital circuitry must be isolated from the analog input signals (AN0 to AN7), analog reference voltage (AVref\*), and analog power supply (AVcc) by the analog ground (AVss). Also, the analog ground (AVss) should be connected at one point to a stable digital ground (Vss) on the board.

Note: \* AVref is available only for the H8S/2144B.

#### 14.7.5 Notes on Noise Countermeasures

A protection circuit connected to prevent damage due to an abnormal voltage such as an excessive surge at the analog input pins (AN0 to AN7) and analog reference voltage (AVref\*) should be connected between AVcc and AVss as shown in figure 14.8. Also, the bypass capacitors connected to AVcc and AVref\*, and the filter capacitor connected to AN2 to AN7, must be connected to AVSS.

If a filter capacitor is connected, the input currents at the analog input pins (AN0 to AN7) are averaged, and so an error may arise. Also, when A/D conversion is performed frequently, as in scan mode, if the current charged and discharged by the capacitance of the sample-and-hold circuit in the A/D converter exceeds the current input via the input impedance (Rin), an error will arise in the analog input pin voltage. Careful consideration is therefore required when deciding the circuit constants.

Note: \* AVref is available only for the H8S/2144B.

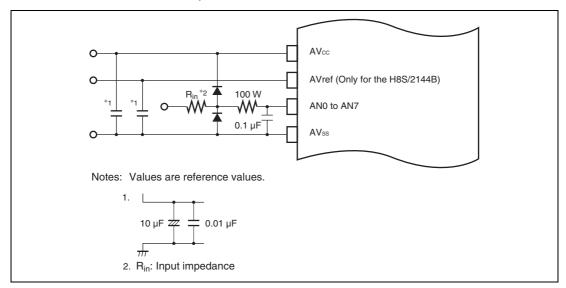

Figure 14.8 Example of Analog Input Protection Circuit

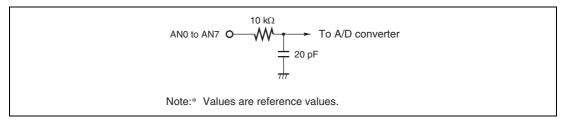

Figure 14.9 Equivalent Circuit of Analog Input Pin

#### 14.7.6 Module Stop Mode Setting

A/D converter operation can be enabled or disabled using the module stop control register. The initial setting is for A/D converter operation to be halted. Register access is enabled by canceling module stop mode. For details, refer to section 18, Power-Down Modes.

# Section 15 RAM

This LSI has an on-chip high-speed static RAM. The RAM is connected to the CPU by a 16-bit data bus, enabling one-state access by the CPU to both byte data and word data.

The on-chip RAM can be enabled or disabled by means of the RAME bit in the system control register (SYSCR). For details on SYSCR, refer to section 3.2.2, System Control Register (SYSCR).

Product Classif	ication	RAM Capacitance	RAM Address
Flash memory version	H8S/2144B	4 kbytes	H'E080 to H'EFFF, H'FF00 to H'FF7F
	H8S/2134B	4 kbytes	H'E080 to H'EFFF, H'FF00 to H'FF7F

# Section 16 ROM

This LSI has an on-chip ROM (flash memory or masked ROM). The features of the flash memory are summarized below.

A block diagram of the flash memory is shown in figure 16.1.

#### 16.1 Features

Size

<b>Product Classification</b>	RAM Capacitance	ROM Address
H8S/2144B	128 kbytes	H'000000 to H'01FFFF (mode 2) H'0000 to H'DFFF (mode 3)
H8S/2134B	128 kbytes	H'000000 to H'01FFFF (mode 2) H'0000 to H'DFFF (mode 3)

#### Programming/erasing methods

The flash memory is programmed 128 bytes at a time. Erasure is performed in single-block units. The flash memory is configured as follows: 32 kbytes  $\times$  2 blocks, 8 kbytes  $\times$  2 blocks, 16 kbytes  $\times$  1 block, 28 kbytes  $\times$  1 block, and 1 kbyte  $\times$  4 blocks

To erase the entire flash memory, each block must be erased in turn.

Programming/erasing time

It takes 10 ms (typ.) to program the flash memory 128 bytes at a time;  $80 \mu s$  (typ.) per 1 byte. Erasing one block takes 100 ms (typ.).

• Reprogramming capability

The flash memory can be reprogrammed up to 100 times.

- Two flash memory on-board programming modes
  - Boot mode
  - User program mode

On-board programming/erasing can be done in boot mode in which the boot program built into the chip is started for erasure or programming of the entire flash memory. In user program mode, individual blocks can be erased or programmed.

• Automatic bit rate adjustment

With data transfer in boot mode, this LSI's bit rate can be automatically adjusted to match the transfer bit rate of the host.

- Programming/erasing protection
   Sets protection against flash memory programming/erasing via hardware, software, or error protection.
- Programmer mode
   In addition to on-board programming mode, programmer mode is supported to program or erase the flash memory using a PROM programmer.

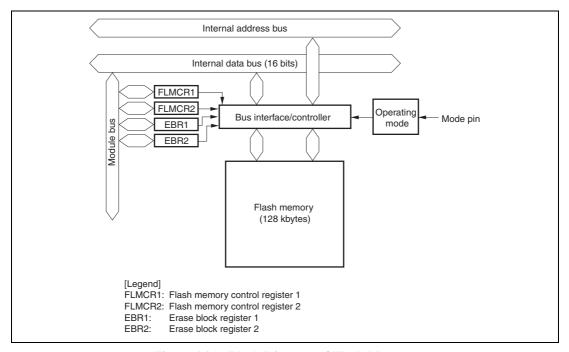

Figure 16.1 Block Diagram of Flash Memory

#### 16.2 Mode Transitions

When the mode pins are set in the reset state and a reset-start is executed, this LSI enters an operating mode as shown in figure 16.2. In user mode, flash memory can be read but not programmed or erased. The boot, user program, and programmer modes are provided as modes to write and erase the flash memory.

The differences between boot mode and user program mode are shown in table 16.1. Figure 16.3 shows the boot mode and figure 16.4 shows the user program mode.

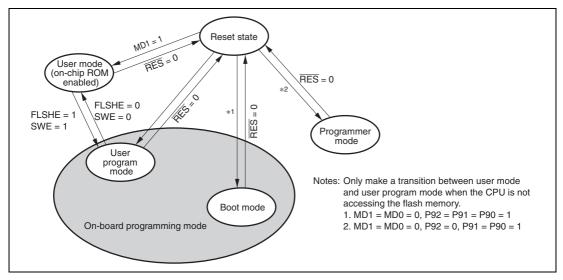

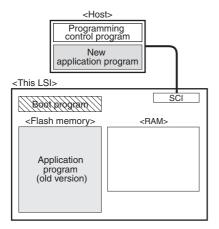

Figure 16.2 Flash Memory State Transitions

Table 16.1 Differences between Boot Mode and User Program Mode

	Boot Mode	User Program Mode
Total erasure	Yes	Yes
Block erasure	No	Yes
Programming control program*	Programming/programming- verifying	Programming/programming- verifying
		Erasing/erasing-verifying

Note: \* Should be provided by the user, in accordance with the recommended algorithm.

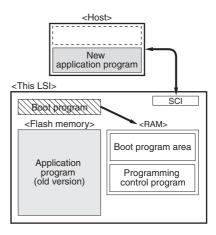

Initial state
 The flash memory is erased at shipment.
 The following describes how to write over an old-version application program or data in the flash memory. The user should prepare the programming control program and new application program beforehand in the host.

Flash memory initialization
 The erase program in the boot program area (in RAM) is executed, and the flash memory is initialized (to H'FF). In boot mode, total flash memory erasure is performed, without regard to blocker.

SCI communication check
 When boot mode is entered, the boot program in
 this LSI (originally incorporated in the chip) is started
 and SCI communication is checked. Then the boot
 program required for flash memory erasing is
 automatically transferred to the RAM boot program

Programming new application program
 The programming control program transferred from
 the host to RAM via SCI communication is executed,
 and the new application program in the host is written
 into the flash memory.

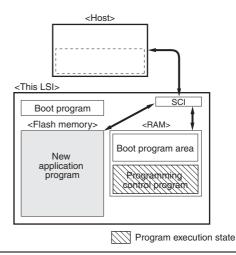

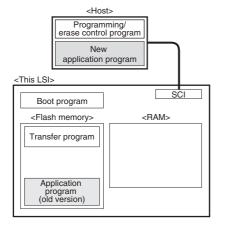

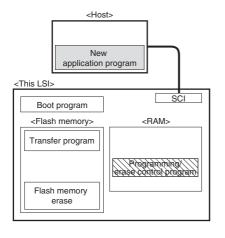

Figure 16.3 Boot Mode

- 1. Initial state
  - (1) The program that will transfer the programming/erase control program from flash memory to on-chip RAM should be written into the flash memory by the user beforehand.
  - (2) The programming/erase control program should be prepared in the host or in the flash memory.

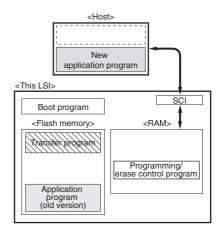

3. Flash memory initialization

The programming/erase program in RAM is executed, and the flash memory is initialized (to H'FF). Erasing can be performed in block units, but not in byte units.

Programming/erase control program transfer
 The transfer program in the flash memory is executed and
 the programming/erase control program is transferred to RAM.

4. Writing new application program

Next, the new application program in the host is written into the erased flash memory blocks. Do not write to unerased blocks.

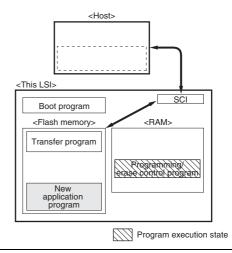

Figure 16.4 User Program Mode (Example)

# 16.3 Block Configuration

#### 16.3.1 Block Configuration

Figure 16.5 shows the block configuration of 128-kbyte flash memory. The thick lines indicate erasing units, the narrow lines indicate programming units, and the values are addresses. The flash memory is divided into 8 kbytes (2 blocks), 16 kbytes (1 block), 28 kbytes (1 block), and 1 kbyte (4 blocks). Erasing is performed in these divided units. Programming is performed in 128-byte units starting from an address whose lower bits are H'00 or H'80.

EB0	H'000000	H'000001	H'000002	← Programming unit: 128 bytes →	H'00007

Figure 16.5 Flash Memory Block Configuration

# 16.4 Input/Output Pins

The flash memory is controlled by means of the pins shown in table 16.2.

**Table 16.2** Pin Configuration

Pin Name	I/O	Function
RES	Input	Reset
MD1	Input	Sets this LSI's operating mode
MD0	Input	Sets this LSI's operating mode
P92	Input	Sets this LSI's operating mode
P91	Input	Sets this LSI's operating mode
P90	Input	Sets this LSI's operating mode
TxD1	Output	Serial transmit data output
RxD1	Input	Serial receive data input

### 16.5 Register Descriptions

The flash memory has the following registers. To access FLMCR1, FLMCR2, EBR1, or EBR2, the FLSHE bit in the serial/timer control register (STCR) should be set to 1. For details on the serial/timer control register, refer to section 3.2.3, Serial/Timer Control Register (STCR).

- Flash memory control register 1 (FLMCR1)
- Flash memory control register 2 (FLMCR2)
- Erase block register 1 (EBR1)
- Erase block register 2 (EBR2)

### 16.5.1 Flash Memory Control Register 1 (FLMCR1)

FLMCR1, used together with FLMCR2, makes the flash memory enter the programming mode, programming-verifying mode, erasure mode, or erasure-verifying mode. For details on register setting, refer to section 16.8, Flash Memory Programming/Erasing.

FLMCR1 is initialized to H'80 by a reset, or in hardware standby mode, software standby mode, sub-active mode, sub-sleep mode, or watch mode.

Bit	Bit Name	Initial Value	R/W	Description
7	FWE	1	R	Flash Write Enable
				Controls programming/erasing of on-chip flash memory. This bit is always read as 0, and cannot be modified.
6	SWE	0	R/W	Software Write Enable
				When this bit is set to 1, flash memory programming/erasing is enabled. When this bit is cleared to 0, the EV, PV, E, and P bits in this register, the ESU and PSU bits in FLMCR2, and all EBR1 and EBR2 bits cannot be set to 1. Do not clear these bits and SWE to 0 simultaneously.
5	_	0	R	Reserved
4	_	0	R	These bits are always read as 0 and cannot be modified.
3	EV	0	R/W	Erasing-Verifying
				When this bit is set to 1 while SWE = 1, the flash memory transits to erasure-verifying mode. When it is cleared to 0, erasure-verifying mode is cancelled.
2	PV	0	R/W	Programming-Verifying
				When this bit is set to 1 while SWE = 1, the flash memory transits to programming-verifying mode. When it is cleared to 0, programming-verifying mode is cancelled.
1	E	0	R/W	Erasure
				When this bit is set to 1 while SWE = 1 and ESU = 1, the flash memory enters the erasing mode. When it is cleared to 0, erasing mode is cancelled.

Bit	Bit Name	Initial Value	R/W	Description
0	Р	0	R/W	Program
				When this bit is set to 1 while SWE = 1 and PSU = 1, the flash memory enters the programming mode. When it is cleared to 0, programming mode is cancelled.

#### 16.5.2 Flash Memory Control Register 2 (FLMCR2)

FLMCR2 monitors the state of flash memory programming/erasing protection (error protection) and sets up the flash memory to transit to programming/erasing mode. FLMCR2 is initialized to H'00 by a reset or in hardware standby mode. The ESU and PSU bits are cleared to 0 in software standby mode, sub-active mode, sub-sleep mode, or watch mode, or when the SWE bit in FLMCR1 is cleared to 0.

Bit	Bit Name	Initial Value	R/W	Description
7	FLER	0	R	Flash memory error
				Indicates that an error has occurred during flash memory programming/erasing. When this bit is set to 1, flash memory goes to the error-protection state.
				For details, see section 16.9.3, Error Protection.
6 to 2	2 —	All 0	R/(W)	Reserved
				The initial values should not be modified.
1	ESU	0	R/W	Erase Setup
				When this bit is set to 1 while SWE = 1, the flash memory transits to the erase setup state. When it is cleared to 0, the erase setup state is cancelled. Set this bit to 1 before setting the E bit in FLMCR1 to 1.
0	PSU	0	R/W	Program Setup
				When this bit is set to 1 while SWE = 1, the flash memory enters the programming setup state. When it is cleared to 0, the programming setup state is cancelled. Set this bit to 1 before setting the P bit in FLMCR1 to 1.

### 16.5.3 Erase Block Registers 1 and 2 (EBR1, EBR2)

EBR1 and EBR2 are used to specify the flash memory erase block. EBR1 and EBR2 are initialized to H'00 by a reset, or in hardware standby mode, software standby mode, sub-active mode, sub-sleep mode, or watch mode, or when the SWE bit in FLMCR1 is cleared to 0. Set only one bit to 1 at a time, otherwise all bits in EBR1 and EBR2 are automatically cleared to 0.

#### EBR1

Bit	Bit Name	Initial Value	R/W	Description
7 to 0	_	All 0	R/(W)	Reserved
				The initial values should not be modified.

#### EBR2

Bit	Bit Name	Initial Value	R/W	Description
7	EB7	0	R/W*	When this bit is set to 1, 8 kbytes of EB7 (H'00E000 to H'00FFFF) are to be erased.
6	EB6	0	R/W	When this bit is set to 1, 8 kbytes of EB6 (H'00C000 to H'00DFFF) are to be erased.
5	EB5	0	R/W	When this bit is set to 1, 16 kbytes of EB5 (H'008000 to H'00BFFF) are to be erased.
4	EB4	0	R/W	When this bit is set to 1, 28 kbytes of EB4 (H'001000 to H'007FFF) are to be erased.
3	EB3	0	R/W	When this bit is set to 1, 1 kbyte of EB3 (H'000C00 to H'000FFF) is to be erased.
2	EB2	0	R/W	When this bit is set to 1, 1 kbyte of EB2 (H'000800 to H'000BFF) is to be erased.
1	EB1	0	R/W	When this bit is set to 1, 1 kbyte of EB1 (H'000400 to H'0007FF) is to be erased.
0	EB0	0	R/W	When this bit is set to 1, 1 kbyte of EB0 (H'000000 to H'0003FF) is to be erased.

Note: \* In normal mode, this bit is always read as 0 and cannot be modified.

# 16.6 Operating Modes

The flash memory is connected to the CPU via a 16-bit data bus, enabling byte data and word data to be accessed in a single state. Even addresses are connected to the upper 8 bits and odd addresses are connected to the lower 8 bits. Note that word data must start from an even address.

On-chip ROM is enabled or disabled by the mode select pins (MD1 and MD0) and the EXPE bit in MDCR, as summarized in table 16.3.

In normal mode (mode 3), up to 56 kbytes of ROM can be used.

Table 16.3 Operating Modes and ROM

	Operatir	ng Modes	Мо	de Pins	MDCR		
MCU Operating Mode	CPU Operating Mode	Mode	MD1	MD0	EXPE	On-Chip ROM	
Mode 1	Normal	Expanded mode with on-chip ROM disabled	0	1	1	Disabled	
Mode 2	Advanced	Single-chip mode	1	0	0	Enabled	
	Advanced	Expanded mode with on-chip ROM enabled	1	0	1	<sup>—</sup> (128 kbytes)	
Mode 3	Normal	Single-chip mode	1	1	0	Enabled	
	Normal	Expanded mode with on-chip ROM enabled	1	1	1	(56 kbytes)	

## 16.7 On-Board Programming Modes

An on-board programming mode is used to perform on-chip flash memory programming, erasing, and verification. This LSI has two on-board programming modes: boot mode and user program mode. Table 16.4 shows pin settings for boot mode. In user program mode, operation by software is enabled by setting control bits. For details on flash memory mode transitions, see figure 16.2.

Table 16.4 On-Board Programming Mode Settings

Mode Setting		MD1	MD0	P92	P91	P90	
Boot mode		0	0	1*	1*	1*	
User program mode	Mode 2 (advanced mode)	1	0	_	_	_	
	Mode 3 (normal mode)	1	1	_	_	_	

Note: \* Can be used as an I/O port after the boot mode activation.

#### 16.7.1 **Boot Mode**

Table 16.5 shows the boot mode operations between reset end and branching to the programming control program.

- 1. When boot mode is used, the flash memory programming control program must be prepared in the host beforehand. Prepare a programming control program in accordance with the description in section 16.8, Flash Memory Programming/Erasing. In boot mode, if any data exists in the flash memory (except in the case that all data are 1), all blocks in the flash memory are erased. Use boot mode at initial writing in the on-board state, or forced recovery when user program mode cannot be executed because the program to be initiated in user program mode was mistakenly erased.
- 2. The SCI\_1 should be set to asynchronous mode, and the transfer format as follows: 8-bit data, 1 stop bit, and no parity.
- 3. When the boot program is initiated, this LSI measures the low-level period of asynchronous SCI communication data (H'00) transmitted continuously from the host. This LSI then calculates the bit rate of transmission from the host, and adjusts the SCI\_1 bit rate to match that of the host. The reset should end with the RxD1 pin high. The RxD1 and TxD1 pins should be pulled up on the board if necessary. After the reset ends, it takes approximately 100 states before this LSI is ready to measure the low-level period.

- 4. After matching the bit rates, this LSI transmits one H'00 byte to the host to indicate the end of bit rate adjustment. The host should confirm that this adjustment end indication (H'00) has been received normally, and transmit one H'55 byte to this LSI. If reception could not be performed normally, initiate boot mode again by a reset. Depending on the host's transfer bit rate and system clock frequency of this LSI, there will be a discrepancy between the bit rates of the host and this LSI. To operate the SCI properly, set the host's transfer bit rate and system clock frequency of this LSI within the ranges listed in table 16.6.
- 5. In boot mode, a part of the on-chip RAM area is used by the boot program. Addresses H'FFE080 to H'FFE87F is the area to which the programming control program is transferred from the host. Note, however, that ID codes are assigned to addresses H'FFE080 to H'FFE087. The boot program area cannot be used until the execution state in boot mode switches to the programming control program. Figure 16.8 shows the on-chip RAM area in boot mode.
- 6. Before branching to the programming control program (H'FFE088 in the RAM area), this LSI terminates transfer operations by the SCI\_1 (by clearing the RE and TE bits in SCR to 0), but the adjusted bit rate value remains set in BRR. Therefore, the programming control program can still use it for transfer of write data or verifying data with the host. The TxD1 pin is in high-level output state. The contents of the CPU general registers are undefined immediately after branching to the programming control program. These registers must be initialized at the beginning of the programming control program, since the stack pointer (SP), in particular, is used implicitly in subroutine calls, etc.
- 7. Boot mode can be cleared by a reset. Cancel the reset\*1 after driving the reset pin low, waiting at least 20 states, and then setting the mode pins. Boot mode is also cleared when a WDT overflow occurs.
- 8. Do not change the mode pin input levels in boot mode. If mode pin input levels are changed from low to high during reset, operating modes are switched and the state of ports that are also used for address output and bus control output signals (AS, RD, and HWR) are changed\*5. Therefore, set these pins carefully not to be output signals during reset or not to conflict with LSI external signals.
- 9. All interrupts are disabled during programming or erasing of the flash memory.
- Notes: 1. After a reset is released, the timing for setting the signal levels on mode pins must satisfy the mode programming setup time ( $t_{MDS} = 4$  cycles).
  - 2. The ports that also have address output functions output low as address output when the mode pins are set to mode 1 during a reset. In modes other than mode 1, it enters the high impedance state. Bus control output signals output high when the mode pins are set to mode 1 during a reset. In modes other than mode 1, it enters the high impedance state.

**Table 16.5 Boot Mode Operation** 

٦	Host Operation	Communications Contents	LSI Operation
Item	Processing Contents		Processing Contents
Boot mode start			Branches to boot program at reset-start.  Boot program start
Bit rate adjustment	Continuously transmits data H'00 at specified bit rate.  Transmits data H'55 when data H'00 is received error-free.  Receives data H'AA.	H'00, H'00 · · · H'00  H'00  H'55	Measures low-level period of receive data H'00. Calculates bit rate and sets it in BRR of SCI_1. Transmits data H'00 to host as adjustment end indication.  After receiving data H'55, transmits data H'AA to host.
Transfer of programming control program	Transmits number of bytes (N) of programming control program to be transferred as 2-byte data (low-order byte following high-order byte).  Transmits 1-byte of programming control program (repeated for N times).	High-order byte and low-order byte  Echoback  H'XX  Echoback	Echobacks the 2-byte data received to host.  Echobacks received data to host and also transfers it to RAM (repeated for N times).
Flash memory erase	Boot program erase error ▼ Receives data H'AA. <del></del>	H'FF H'AA	Checks flash memory data, erases all flash memory blocks in case of written data existing, and transmits data H'AA to host. (If erase could not be done, transmits data H'FF to host and aborts operation.)
		ı	Branches to programming control program transferred to on-chip RAM and starts execution.

Table 16.6 System Clock Frequencies for which Automatic Adjustment of LSI Bit Rate is Possible

Host Bit Rate	System Clock Frequency Range of This LSI
19200 bps	8 to 20 MHz
9600 bps	4 to 20 MHz
4800 bps	2 to 18 MHz

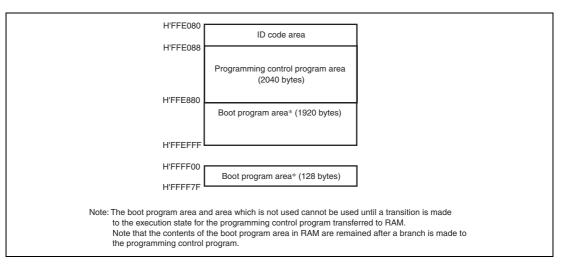

Figure 16.6 On-Chip RAM Area in Boot Mode

In boot mode, this LSI checks the contents of the 8-byte ID code area as shown below to confirm that the programming control program corresponds with this LSI. To originally write a programming control program to be used in boot mode, the above 8-byte ID code must be added at the beginning of the program.

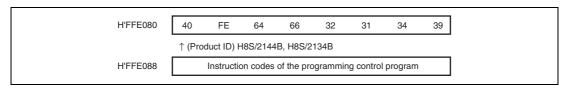

Figure 16.7 ID Code Area

### 16.7.2 User Program Mode

On-board programming/erasing of an individual flash memory block can also be performed in user program mode by branching to a user programming/erasing control program. The user must set branching conditions and provide on-board means of supplying programming data. The flash memory must contain the user programming/erasing control program or a program which provides the user programming/erasing control program from external memory. Because the flash memory itself cannot be read during programming/erasing, transfer the user programming/erasing control program to on-chip RAM, as like in boot mode. Figure 16.10 shows a sample procedure for programming/erasing in user program mode. Prepare a user programming/erasing control program in accordance with the description in section 16.8, Flash Memory Programming/Erasing.

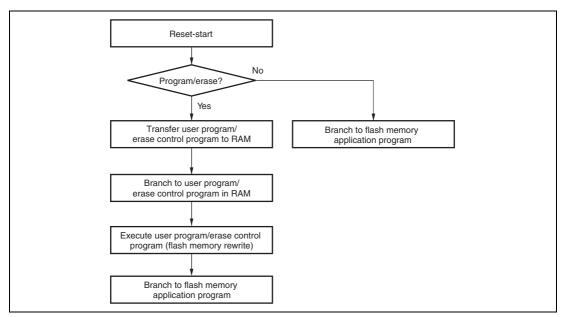

Figure 16.8 Programming/Erasing Flowchart Example in User Program Mode

## 16.8 Flash Memory Programming/Erasing

A software method, using the CPU, is employed to program and erase flash memory in the on-board programming modes. Depending on the FLMCR1 and FLMCR2 settings, the flash memory operates in one of the following four modes: programming mode, programming-verifying mode, erasing mode, and erasing-verifying mode. The programming control program in boot mode and the user programming/erasing control program in user program mode use these operating modes in combination to perform programming/erasing. Flash memory programming and erasing should be performed in accordance with the descriptions in section 16.8.1, Programming/Programming-Verifying and section 16.8.2, Erasing/Erasing-Verifying, respectively.

### 16.8.1 Programming/Programming-Verifying

When writing data or programs to the flash memory, the programming/programming-verifying flowchart shown in figure 16.11 should be followed. Performing programming operations according to this flowchart will enable data or programs to be written to the flash memory without subjecting this LSI to voltage stress or sacrificing program data reliability.

- 1. Programming must be done to an empty address. Do not reprogram an address to which programming has already been performed.
- 2. Programming should be carried out 128 bytes at a time. A 128-byte data transfer must be performed even if writing fewer than 128 bytes. In this case, H'FF data must be written to the extra addresses.
- 3. Prepare the following data storage areas in RAM: a 128-byte programming data area, a 128-byte reprogramming data area, and a 128-byte additional-programming data area. Perform reprogramming data computation and additional programming data computation according to figure 16.9.
- 4. Consecutively transfer 128 bytes of data in byte units from the reprogramming data area or additional-programming data area to the flash memory. The programming address and 128-byte data are latched in the flash memory. The lower 8 bits of the start address in the flash memory destination area must be H'00 or H'80.
- 5. The time during which the P bit is set to 1 is the programming time. Figure 16.9 shows the allowable programming times.
- 6. The watchdog timer (WDT) is set to prevent overprogramming due to program runaway, etc. The overflow cycle should be longer than  $(y + z2 + \alpha + \beta) \mu s$ .
- 7. For a dummy write to a verify address, write 1-byte data H'FF to an address whose lower 2 bits are B'00. Verify data can be read in words from the address to which a dummy write was performed.

8. The maximum number of repetitions of the programming/programming-verifying sequence to the same bit is (N).

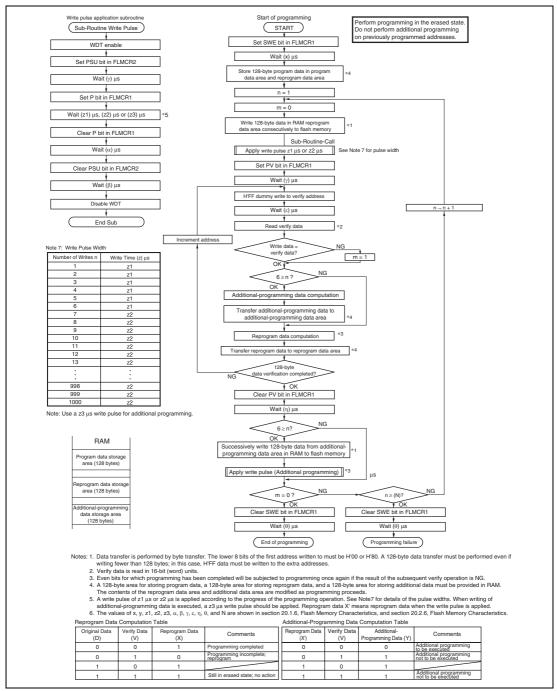

Figure 16.9 Programming/Programming-Verifying Flowchart

### 16.8.2 Erasing/Erasing-Verifying

When erasing flash memory, the erasing/erasing-verifying flowchart shown in figure 16.10 should be followed.

- 1. Prewriting (setting erase block data to all 0) is not necessary.
- 2. Erasing is performed in block units. Make only a single-block specification in erase block registers 1 and 2 (EBR1 and EBR2). To erase multiple blocks, each block must be erased in turn.
- 3. The time during which the E bit is set to 1 is the flash memory erase time.
- 4. The watchdog timer (WDT) is set to prevent overprogramming due to program runaway, etc. An overflow cycle of approximately  $(y + z + \alpha + \beta)$  ms is allowed.
- For a dummy write to a verify address, write 1-byte data H'FF to an address whose lower two bits are B'00. Verify data can be read in longwords from the address to which a dummy write was performed.
- 6. If the read data is unerased, set erase mode again, and repeat the erasing/erasure-verifying sequence as before. The maximum number of repetitions of the erasing/erasure-verifying sequence is N.

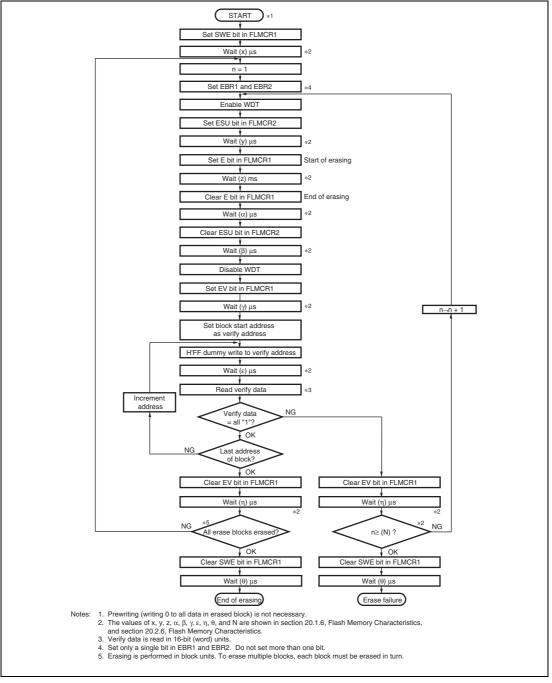

Figure 16.10 Erasing/Erasing-Verifying Flowchart

## 16.9 Programming/Eraseing Protection

There are three kinds of flash memory programming/erasing protection: hardware protection, software protection, and error protection.

#### 16.9.1 Hardware Protection

Hardware protection is a state in which programming/erasing of flash memory is forcibly disabled or aborted by a reset (including WDT overflow reset), or a transition to hardware standby mode, software standby mode, sub-active mode, sub-sleep mode or watch mode. Flash memory control registers 1 and 2 (FLMCR1 and FLMCR2) and erase block registers 1 and 2 (EBR1 and EBR2) are initialized. In a reset via the  $\overline{RES}$  pin, the reset state is not entered unless the  $\overline{RES}$  pin is held low until oscillation stabilizes after powering on. In the case of a reset during operation, hold the  $\overline{RES}$  pin low for the  $\overline{RES}$  pulse width specified in the AC Characteristics section.

#### 16.9.2 Software Protection

Software protection can be implemented against programming/erasing of all flash memory blocks by clearing the SWE bit in FLMCR1 to 0. When software protection is in effect, setting the P or E bit in FLMCR1 does not cause a transition to program mode or erase mode. By setting the erase block registers 1 and 2 (EBR1 and EBR2), erase protection can be set for individual blocks. When EBR1 and EBR2 are set to H'00, erase protection is set for all blocks.

#### 16.9.3 Error Protection

In error protection, an error is detected when the CPU's runaway occurs during flash memory programming/erasing, or operation is not performed in accordance with the programming/erasing algorithm, and the programming/erasing operation is aborted. Aborting the programming/erasing operation prevents damage to the flash memory due to overprogramming or overerasing.

When the following errors are detected during programming/erasing of flash memory, the FLER bit in FLMCR2 is set to 1, and the error protection state is entered.

- When the flash memory of is read during programming/erasing (including vector read and instruction fetch)
- Immediately after exception handling (excluding a reset) during programming/erasing
- When a SLEEP instruction is executed (transits to software standby mode, sleep mode, sub-active mode, sub-sleep mode, or watch mode) during programming/erasing
- When the bus ownership is released during programming/erasing

The FLMCR1, FLMCR2, EBR1, and EBR2 settings are retained, but programming mode or erase mode is aborted at the point at which the error occurred. Program mode or erase mode cannot be entered by setting the P or E bit to 1. However, because the PV and EV bit settings are retained, a transition to the verifying mode can be made. The error protection state can be cancelled by a reset or in hardware standby mode.

## 16.10 Interrupts during Flash Memory Programming/Erasing

In order to give the highest priority to programming/erasing operations, disable all interrupts including NMI input during flash memory programming/erasing (the P or E bit in FlMCR1 is set to 1) or boot program execution\*<sup>1</sup>.

- 1. If an interrupt is generated during programming/erasing, operation in accordance with the programming/erasing algorithm is not guaranteed.
- 2. CPU runaway may occur because normal vector reading cannot be performed in interrupt exception handling during programming/erasing\*<sup>2</sup>.
- 3. If an interrupt occurs during boot program execution, the normal boot mode sequence cannot be executed.
- Notes: 1. Interrupt requests must be disabled inside and outside the CPU until the programming control program has completed programming.
  - The vector may not be read correctly for the following two reasons:
     If flash memory is read while being programmed or erased (while the P or E bit in FLMCR1 is set to 1), correct read data will not be obtained (undefined values will be returned).
    - If the interrupt entry in the vector table has not been programmed yet, interrupt exception handling will not be executed correctly.

## 16.11 Programmer Mode

In programmer mode, the on-chip flash memory can be programmed/erased by a PROM programmer via a socket adapter, just like for a discrete flash memory. Use a PROM programmer that supports Renesas Technology 128-kbyte flash memory for microcomputer built-in type\*. Figure 16.11 shows a memory map in programmer mode.

Note: Set the programming voltage of the PROM programmer to 3.3V.

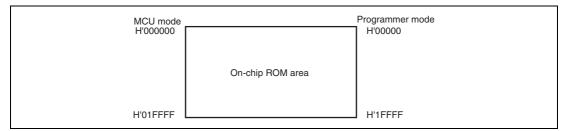

Figure 16.11 Memory Map in Programmer Mode

## 16.12 Usage Notes

The following lists notes on the use of on-board programming modes and programmer mode.

- Perform programming/erasing with the specified voltage and timing.
   If a voltage higher than the rated voltage is applied, the product may be fatally damaged. Use a PROM programmer that supports Renesas Technology 128-kbyte flash memory for microcomputer built-in type. Do not set the programmer to HN28F101 or the programming voltage to 5.0 V.
- 2. Notes on power on/off
  - At powering on or off the Vcc power supply, fix the RES pin to low and set the flash memory to hardware protection state. This power on/off timing must also be satisfied at a power-off and power-on caused by a power failure and other factors.
- 3. Perform flash memory programming/erasing in accordance with the recommended algorithm. In the recommended algorithm, flash memory programming/erasing can be performed without subjecting this LSI to voltage stress or sacrificing program data reliability. When setting the P or E bit in FLMCR1 to 1, set the watchdog timer against program runaway.

- 4. Do not set/clear the SWE bit during program execution in the flash memory.
  - Do not set/clear the SWE bit during program execution in the flash memory. An interval of at least 100 µs is necessary between program execution or data reading in flash memory and SWE bit clearing. When the SWE bit is set to 1, flash memory data can be modified, however, flash memory data can be read only in programming-verifying or erasing-verifying mode. Do not access the flash memory for a purpose other than verification during programming/erasing. Do not clear the SWE bit during programming, erasing, or verifying.
- Do not use interrupts during flash memory programming/erasing
   In order to give the highest priority to programming/erasing operation, disable all interrupts including NMI input when the flash memory is programmed or erased.
- 6. Do not perform additional programming. Programming must be performed in the erased state. Program the area with 128-byte programming-unit blocks in on-board programming or programmer mode only once. Perform programming in the state where the programming-unit block is fully erased.
- 7. Ensure that the PROM programmer is correctly attached before programming. If the socket, socket adapter, or product index does not match the specifications, too much current flows and the product may be damaged.
- Do not touch the socket adapter or LSI while programming.
   Touching either of these can cause contact faults and write errors.

# Section 17 Clock Pulse Generator

This LSI incorporates a clock pulse generator, which generates the system clock ( $\phi$ ), bus master clock, and internal clock.

The clock pulse generator consists of an oscillator, duty correction circuit, clock select circuit, medium-speed clock divider, bus master clock select circuit, subclock input circuit, and waveform forming circuit. Figure 17.1 shows a block diagram of the clock pulse generator.

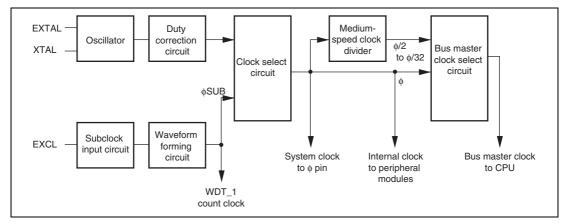

Figure 17.1 Block Diagram of Clock Pulse Generator

The bus master clock is selected as either high-speed mode or medium-speed mode by software according to the settings of the SCK2 to SCK0 bits in the standby control register. For details on the standby control register, refer to section 18.1.1, Standby Control Register (SBYCR).

The subclock input is controlled by software according to the EXCLE bit setting in the low power control register. For details on the low power control register, refer to section 18.1.2, Low Power Control Register (LPWRCR).

#### 17.1 Oscillator

Clock pulses can be supplied either by connecting a crystal resonator, or by providing external clock input.

#### 17.1.1 Connecting Crystal Resonator

Figure 17.2 shows a typical method of connecting a crystal resonator. An appropriate damping resistance  $R_a$ , given in table 17.1, should be used. An AT-cut parallel-resonance crystal resonator should be used.

Figure 17.3 shows the equivalent circuit of a crystal resonator. A resonator having the characteristics given in table 17.2 should be used.

A crystal resonator with frequency identical to that of the system clock (\$\phi\$) should be used.

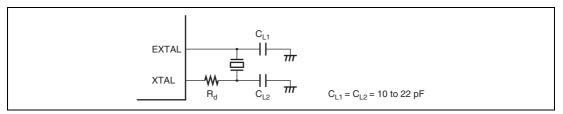

Figure 17.2 Typical Connection to Crystal Resonator

**Table 17.1 Damping Resistance Values** 

Frequency (MHz)	2	4	8	10	12	16	20
$R_{d}(\Omega)$	1 k	500	200	0	0	0	0

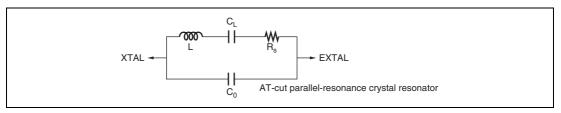

Figure 17.3 Equivalent Circuit of Crystal Resonator

**Table 17.2 Crystal Resonator Parameters** 

Frequency (MHz)	2	4	8	10	12	16	20	
$R_s$ (max) ( $\Omega$ )	500	120	80	70	60	50	40	
C <sub>0</sub> (max) (pF)				7				

### 17.1.2 External Clock Input Method

Figure 17.4 shows a typical method of connecting an external clock signal. To leave the XTAL pin open, incidental capacitance should be 10 pF or less.

To input an inverted clock to the XTAL pin, the external clock should be set to high in standby mode, subactive mode, subsleep mode, and watch mode. External clock input conditions are shown in table 17.3. The frequency of the external clock should be the same as that of the system clock  $(\phi)$ .

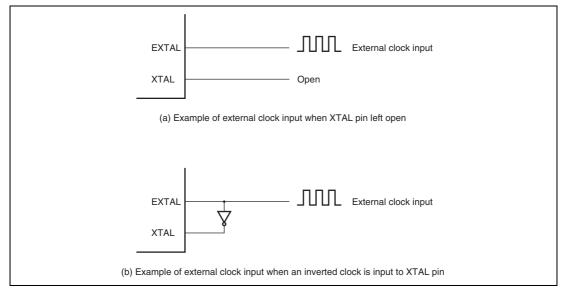

Figure 17.4 Example of External Clock Input

**Table 17.3 External Clock Input Conditions** 

		V <sub>cc</sub> = 5.5 V	4.0 to	V <sub>cc</sub> = 5.0 V ± 10 %				
Item	Symbol	Min.	Max.	Min.	Max.	Unit	Test Conditi	ons
External clock input pulse width low level	t <sub>EXL</sub>	25	_	20	_	ns	Figure 17.5	
External clock input pulse width high level	t <sub>EXH</sub>	25	_	20	_	ns	_	
External clock rising time	t <sub>EXr</sub>	_	5	_	5	ns	_	
External clock falling time	t <sub>exf</sub>	_	5	_	5	ns	_	
Clock pulse width low level	t <sub>cL</sub>	0.4	0.6	0.4	0.6	t <sub>cyc</sub>	$\varphi \geq 5 \text{ MHz}$	Figure
		80	_	80	_	ns	$\phi$ < 5 MHz	20.4
Clock pulse width high	t <sub>ch</sub>	0.4	0.6	0.4	0.6	t <sub>cyc</sub>	φ≥5 MHz	_
level		80		80	_	ns	φ < 5 MHz	_

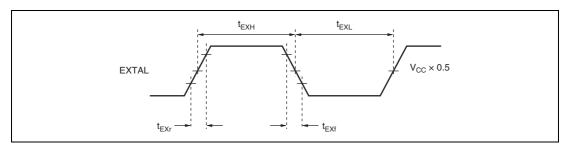

Figure 17.5 External Clock Input Timing

The oscillator and duty correction circuit have a function to adjust the waveform of the external clock input that is input to the EXTAL pin. When a specified clock signal is input to the EXTAL pin, internal clock signal output is determined after the external clock output stabilization delay time  $(t_{\text{DEXT}})$  has passed. As the clock signal output is not determined during the  $t_{\text{DEXT}}$  cycle, a reset signal should be set to low to hold it in reset state. Table 17.4 shows the external clock output stabilization delay time. Figure 17.6 shows the timing of the external clock output stabilization delay time.

Table 17.4 External Clock Output Stabilization Delay Time

Condition:  $V_{cc} = 4.0 \text{ V}$  to 5.5 V,  $AV_{cc} = 4.0 \text{ V}$  to 5.5 V,  $V_{ss} = AV_{ss} = 0 \text{ V}$ 

Item	Symbol	Min.	Max.	Unit	Remarks
External clock output stabilization delay time	t <sub>DEXT</sub> *	500	_	μs	Figure 17.6

Note: \*  $t_{DEXT}$  includes a  $\overline{RES}$  pulse width  $(t_{RESW})$ .

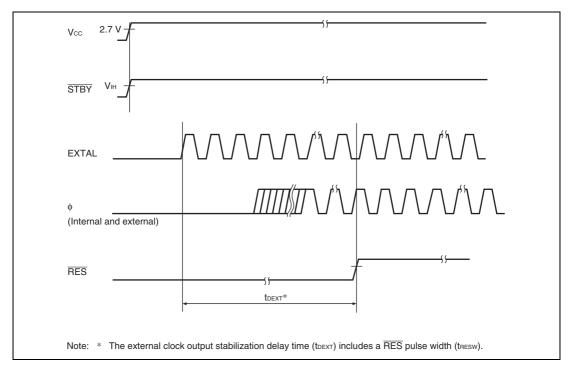

Figure 17.6 Timing of External Clock Output Stabilization Delay Time

## 17.2 Duty Correction Circuit

The duty correction circuit is valid when the oscillating frequency is 5 MHz or more. It corrects the duty of a clock that is output from the oscillator, and generates the system clock ( $\phi$ ).

## 17.3 Medium-Speed Clock Divider

The medium-speed clock divider divides the system clock ( $\phi$ ), and generates  $\phi/2$ ,  $\phi/4$ ,  $\phi/8$ ,  $\phi/16$ , and  $\phi/32$  clocks.

#### 17.4 Bus Master Clock Select Circuit

The bus master clock select circuit selects a clock to supply the bus master with either the system clock ( $\phi$ ) or medium-speed clock ( $\phi$ /2,  $\phi$ /4,  $\phi$ /8,  $\phi$ /16, or  $\phi$ /32) by the SCK2 to SCK0 bits in SBYCR.

## 17.5 Subclock Input Circuit

The subclock input circuit controls subclock input from the EXCL pin. To use the subclock, a 32.768-kHz external clock should be input from the EXCL pin. At this time, the P96DDR bit in P9DDR should be cleared to 0, and the EXCLE bit in LPWRCR should be set to 1.

Subclock input conditions are shown in table 17.5. When the subclock is not used, subclock input should not be enabled.

**Table 17.5 Subclock Input Conditions** 

	V	cc = 4.0 to	5.5 V		Measurement	
Item	Symbol	Min.	Тур.	Max.	Unit	Condition
Subclock input pulse width low level	t <sub>EXCLL</sub>	_	15.26	_	μs	Figure 17.7
Subclock input pulse width high level	t <sub>EXCLH</sub>	_	15.26	_	μs	
Subclock input rising time	t <sub>EXCLr</sub>	_	_	10	ns	_
Subclock input falling time	t	_	_	10	ns	

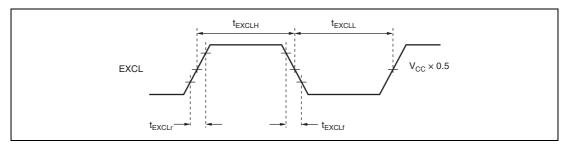

Figure 17.7 Subclock Input Timing

## 17.6 Subclock Waveform Forming Circuit

To remove noise from the subclock input at the EXCL pin, the subclock is sampled by a divided  $\phi$  clock. The sampling frequency is set by the NESEL bit in LPWRCR.

The subclock is not sampled in subactive mode, subsleep mode, or watch mode.

#### 17.7 Clock Select Circuit

The clock select circuit selects the system clock that is used in this LSI.

A clock generated by an oscillator to which the EXTAL and XTAL pins are input is selected as a system clock when returning from high-speed mode, medium-speed mode, sleep mode, reset state, or standby mode.

A subclock input from the EXCL pin is selected as a system clock in subactive mode, subsleep mode, or watch mode. At this time, modules such as the CPU, TMR\_0, TMR\_1, WDT\_0, WDT\_1, ports, and interrupt controller and their functions operate depending on the φSUB. The count clock and sampling clock for each timer are divided φSUB clocks.

## 17.8 Usage Notes

#### 17.8.1 Note on Resonator

Since all kinds of characteristics of the resonator are closely related to the board design by the user, use the example of resonator connection in this document for only reference; be sure to use an resonator that has been sufficiently evaluated by the user. Consult with the resonator manufacturer about the resonator circuit ratings which vary depending on the stray capacitances of the resonator and installation circuit. Make sure the voltage applied to the oscillator pins does not exceed the maximum rating.

### 17.8.2 Notes on Board Design

When using a crystal resonator, the crystal resonator and its load capacitors should be placed as close as possible to the XTAL and EXTAL pins.

Other signal lines should be routed away from the oscillator circuit to prevent inductive interference with the correct oscillation as shown in figure 17.8.

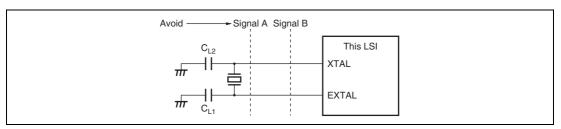

Figure 17.8 Note on Board Design of Oscillator Circuit Section

# Section 18 Power-Down Modes

For operating modes after the reset state is released, this LSI has not only the normal program execution state but also seven power-down modes in which power dissipation is significantly reduced. In addition, there is also module stop mode in which reduced power dissipation can be achieved by individually stopping on-chip peripheral modules.

- Medium-speed mode
   System clock frequency for the CPU operation can be selected as φ/2, φ/4, φ/8, φ/16,or φ/32.
- Subactive mode
   The CPU operates based on the subclock and on-chip peripheral modules other than TMR\_0, TMR\_1, WDT\_0, and WDT\_1 stop operating.
- Sleep mode
   The CPU stops but on-chip peripheral modules continue operating.
- Subsleep mode
   The CPU and on-chip peripheral modules other than TMR\_0, TMR\_1, WDT\_0, and WDT\_1 stop operating.
- Watch mode
   The CPU and on-chip peripheral modules other than WDT\_1 stop operating.
- Software standby mode
   Clock oscillation stops, and the CPU and on-chip peripheral modules stop operating.
- Hardware standby mode
   Clock oscillation stops, and the CPU and on-chip peripheral modules enter reset state.
- Module stop mode
   Independently of above operating modes, on-chip peripheral modules that are not used can be stopped individually.

## **18.1** Register Descriptions

Power-down modes are controlled by the following registers. To access SBYCR, LPWRCR, MSTPCRH, and MSTPCRL, the FLSHE bit in the serial timer control register (STCR) must be cleared to 0. For details on STCR, see section 3.2.3, Serial Timer Control Register (STCR).

- Standby control register (SBYCR)
- Low power control register (LPWRCR)
- Module stop control register H (MSTPCRH)
- Module stop control register L (MSTPCRL)

# 18.1.1 Standby Control Register (SBYCR)

SBYCR controls power-down modes.

		Initial		
Bit	Bit Name	Value	R/W	Description
7	SSBY	0	R/W	Software Standby
				Specifies the operating mode to be entered after executing the SLEEP instruction.
				When the SLEEP instruction is executed in high-speed mode or medium-speed mode:
				0: Shifts to sleep mode
				1: Shifts to software standby mode, subactive mode, or watch mode
				When the SLEEP instruction is executed in subactive mode:
				0: Shifts to subsleep mode
				1: Shifts to watch mode or high-speed mode
				Note that the SSBY bit is not changed even if a mode transition occurs by an interrupt.
6	STS2	0	R/W	Standby Timer Select 2 to 0
5	STS1	0	R/W	Selects the wait time for clock stabilization from clock
4	STS0	0	R/W	oscillation start when canceling software standby mode, watch mode, or subactive mode. Select a wait time of 8 ms (oscillation stabilization time) or more, depending on the operating frequency. Table 18.1 shows the relationship between the STS2 to STS0 values and wait time.
				With an external clock, there are no specific wait requirements. Normally the minimum value is recommended.
3	_	0	R	Reserved
				This bit is always read as 0, and cannot be modified.

Bit	Bit Name	Initial Value	R/W	Description
2	SCK2	0	R/W	System Clock Select 2 to 0
1	SCK1	0	R/W	Selects a clock for the bus master in high-speed mode or
0	SCK0	0	R/W	medium-speed mode.
				When making a transition to subactive mode or watch mode, SCK2 to SCK0 must be cleared to 0.
				000: High-speed mode
				001: Medium-speed clock: φ/2
				010: Medium-speed clock: φ/4
				011: Medium-speed clock: φ/8
				100: Medium-speed clock: φ/16
				101: Medium-speed clock: φ/32
				11X: —

Legend

X: Don't care

Table 18.1 Operating Frequency and Wait Time

STS2	STS1	STS0	Wait Time	20 MHz	10 MHz	8 MHz	6 MHz	4 MHz	2 MHz	Unit
0	0	0	8192 states	0.4	8.0	1.0	1.3	20.	4.1	ms
0	0	1	16384 states	8.0	1.6	2.0	2.7	4.1	8.2	
0	1	0	32768 states	2.0	3.3	4.1	5.5	8.2	16.4	_

1	1	0	Reserved	_		_		_	_	_
1	1	1	16 states*	0.8	1.6	2.0	2.7	4.0	8.0	μs

Shaded cells indicate the recommended specification.

Note: \* This setting cannot be made in the flash-memory version of this LSI.

# 18.1.2 Low-Power Control Register (LPWRCR)

LPWRCR controls power-down modes.

7 DTON 0 R/W Direct Transfer On Flag Specifies the operating mode to be entered after executing the SLEEP instruction. When the SLEEP instruction is executed in high-speed mode or medium-speed mode. 0: Shifts to sleep mode, software standby mode, or watch mode 1: Shifts directly to subactive mode, or shifts to sleep mode or software standby mode When the SLEEP instruction is executed in subactive mode: 0: Shifts to subsleep mode or watch mode 1: Shifts directly to high-speed mode, or shifts to subsleep mode 6 LSON 0 R/W Low-Speed On Flag Specifies the operating mode to be entered after executing the SLEEP instruction. This bit also controls whether to shift to high-speed mode or subactive mode when watch mode is released. When the SLEEP instruction is executed in high-speed mode or medium-speed mode: 0: Shifts to sleep mode, software standby mode, or watch mode 1: Shifts to watch mode or subactive mode When the SLEEP instruction is executed in subactive mode: 0: Shifts directly to watch mode or high-speed mode 1: Shifts to subsleep mode or watch mode When watch mode is released: 0: Shifts to high-speed mode 1: Shifts to subsleep mode	Bit	Bit Name	Initial	R/W	Description
Specifies the operating mode to be entered after executing the SLEEP instruction.  When the SLEEP instruction is executed in high-speed mode or medium-speed mode:  0: Shifts to sleep mode, software standby mode, or watch mode  1: Shifts directly to subactive mode, or shifts to sleep mode or software standby mode  When the SLEEP instruction is executed in subactive mode:  0: Shifts to subsleep mode or watch mode  1: Shifts directly to high-speed mode, or shifts to subsleep mode  6 LSON 0 R/W Low-Speed On Flag  Specifies the operating mode to be entered after executing the SLEEP instruction. This bit also controls whether to shift to high-speed mode or subactive mode when watch mode is released.  When the SLEEP instruction is executed in high-speed mode or medium-speed mode:  0: Shifts to sleep mode, software standby mode, or watch mode  1: Shifts to watch mode or subactive mode  When the SLEEP instruction is executed in subactive mode:  0: Shifts directly to watch mode or high-speed mode  1: Shifts to subsleep mode or watch mode  When watch mode is released:  0: Shifts to high-speed mode					•
the SLEEP instruction. Bit	Bit Name	Initial Value	R/W	Description
5	NESEL	0	R/W	Noise Elimination Sampling Frequency Select
				Selects the frequency by which the subclock ( $\phi$ SUB) input from the EXCL pin is sampled using the clock ( $\phi$ ) generated by the system clock pulse generator. Clear this bit to 0 when $\phi$ is 5 MHz or more.
				0: Sampling using φ/32 clock
				1: Sampling using φ/4 clock
4	EXCLE	0	R/W	Subclock Input Enable
				Enables/disables subclock input from the EXCL pin.
				0: Disables subclock input from the EXCL pin
				1: Enables subclock input from the EXCL pin
3	_	0	R/W	Reserved
				An undefined value is read from this bit. This bit should not be set to 1.
2 to 0	) —	All 0	R	Reserved
				These bits are always read as 0 and cannot be modified.

## 18.1.3 Module Stop Control Registers H and L (MSTPCRH, MSTPCRL)

MSTPCRH and MSTPCRL specify on-chip peripheral modules to shift to module stop mode in module units. Each module can enter module stop mode by setting the corresponding bit to 1.

#### MSTPCRH

Bit	Bit Name	Initial Value	R/W	Corresponding Module
				- Control portains in Cause
7	MSTP15	0*	R/W	_
6	MSTP14	0	R/W	_
5	MSTP13	1	R/W	16-bit free-running timer (FRT)
4	MSTP12	1	R/W	8-bit timers (TMR_0, TMR_1)
3	MSTP11	1	R/W	14-bit PWM timer (PWMX)
2	MSTP10	1	R/W	D/A converter
1	MSTP9	1	R/W	A/D converter
0	MSTP8	1	R/W	8-bit timer (TMR_Y)

Note: \* Do not set this bit to 1.

#### MSTPCRL

Bit	Bit Name	Initial Value	R/W	Corresponding Module
7	MSTP7	1	R/W	Serial communication interface_0 (SCI_0)
6	MSTP6	1	R/W	Serial communication interface_1 (SCI_1)
5	MSTP5	1	R/W	Serial communication interface_2 (SCI_2)
4	MSTP4	1	R/W	_
3	MSTP3	1	R/W	_
2	MSTP2	1	R/W	Keyboard matrix interrupt mask register (KMIMR), keyboard matrix interrupt mask register A (KMIMRA), port 6 pull-up MOS control register (KMPCR)
1	MSTP1	1*	R/W	_
0	MSTP0	1	R/W	_

Note: \* This bit can be read from or written to, however, operation is not affected.

### 18.2 Mode Transitions and LSI States

Figure 18.1 shows the enabled mode transition diagram. The mode transition from program execution state to program halt state is performed by the SLEEP instruction. The mode transition from program halt state to program execution state is performed by an interrupt. The  $\overline{STBY}$  input causes a mode transition from any state to hardware standby mode. The  $\overline{RES}$  input causes a mode transition from a state other than hardware standby mode to the reset state. Table 18.2 shows the LSI internal states in each operating mode.

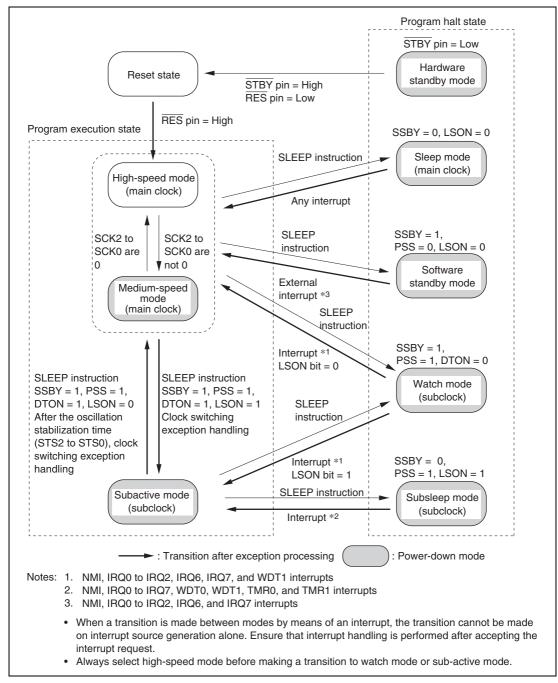

Figure 18.1 Mode Transition Diagram

Table 18.2 LSI Internal States in Each Mode

Function  System clock pulse generator  Subclock pulse generator		High- Speed  Function- ing  Function- ing	Medium- Speed  Function- ing  Function- ing	Sleep Functioning Functioning	Module Stop Function- ing Function- ing	Watch Halted Functioning	Sub- Active Halted Function- ing	Sub- Sleep Halted Function- ing	Software Standby  Halted  Halted	Hardware Standby Halted Halted											
											CPU	Instruction execution	Function- ing	Medium- speed operation	Halted	Function- ing	Halted	Subclock Ha operation	Halted	Halted	Halted
												Registers	_		Retained	_	Retained	_	Retained	Retained	Undefined
External	NMI	Function-	Function- ing	Function- ing	Function-	Function- ing	Function- ing	Function- ing	Function-	Halted											
interrupts	IRQ0 to IRQ7	ing			ing				ing												
	KIN0 to KIN15																				
Peripheral modules	WDT_1	Function- ing	Function- ing	Function- ing	Function- ing	Subclock operation	Subclock operation	Subclock operation	Halted (retained)	Halted (reset)											
	WDT_0	_			Halte	Halted	_														
	TMR_0, TMR_1				Function- ing/Halted	(retained)															
	FRT	_			(retained)		Halted	Halted	=												
	TMR_Y	_					(retained)	(retained)													
	SCI_0	_			Function-	Halted	Halted	Halted	Halted	_											
	SCI_1	-			ing/Halted (reset)	(reset)	(reset)	(reset)	(reset)												
	SCI_2																				
	PWMX																				
	D/A converter																				
	A/D converter	_																			
	RAM	_			Function-	Retained	Function-	Retained	Retained	Retained											
	I/O	_			ing		ing	Function- ing	_	High impedance											

Note: \* "Halted (retained)" means that internal register values are retained. The internal state is "operation suspended."

"Halted (reset)" means that internal register values and internal states are initialized. In module stop mode, only modules for which a stop setting has been made are halted (reset or retained).

## 18.3 Medium-Speed Mode

The CPU makes a transition to medium-speed mode as soon as the current bus cycle ends according to the setting of the SCK2 to SCK0 bits in SBYCR. In medium-speed mode, the CPU operates on the operating clock ( $\phi/2$ ,  $\phi/4$ ,  $\phi/8$ ,  $\phi/16$ , or  $\phi/32$ ). On-chip peripheral modules other than the bus masters always operate on the system clock ( $\phi$ ).

In medium-speed mode, a bus access is executed in the specified number of states with respect to the bus master operating clock. For example, if  $\phi/4$  is selected as the operating clock, on-chip memory is accessed in 4 states, and internal I/O registers in 8 states.

By clearing all of bits SCK2 to SCK0 to 0, a transition is made to high-speed mode at the end of the current bus cycle.

If a SLEEP instruction is executed when the SSBY bit in SBYCR is cleared to 0, and the LSON bit in LPWRCR is cleared to 0, a transition is made to sleep mode. When sleep mode is cleared by an interrupt, medium-speed mode is restored. When the SLEEP instruction is executed with the SSBY bit set to 1, the LSON bit cleared to 0, and the PSS bit in TCSR (WDT\_1) cleared to 0, operation shifts to software standby mode. When software standby mode is cleared by an external interrupt, medium-speed mode is restored.

When the  $\overline{RES}$  pin is set low and medium-speed mode is released, operation shifts to the reset state. The same applies in the case of a reset caused by overflow of the watchdog timer.

When the STBY pin is driven low, medium-speed mode is released and a transition is made to hardware standby mode.

Figure 18.2 shows an example of medium-speed mode timing.

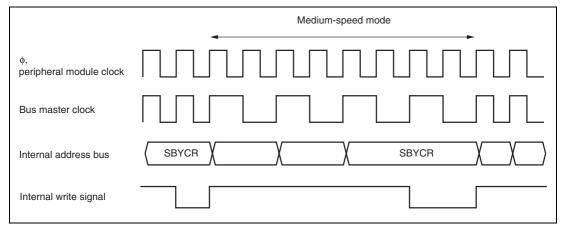

Figure 18.2 Medium-Speed Mode Timing

## 18.4 Sleep Mode

The CPU makes a transition to sleep mode if the SLEEP instruction is executed when the SSBY bit in SBYCR is cleared to 0 and the LSON bit in LPWRCR is cleared to 0. In sleep mode, CPU operation stops but the peripheral modules do not stop. The contents of the CPU's internal registers are retained.

Sleep mode is exited by any interrupt, the  $\overline{RES}$  pin, or the  $\overline{STBY}$  pin.

When an interrupt occurs, sleep mode is exited and interrupt exception handling starts. Sleep mode is not exited if the interrupt is disabled, or interrupts other than NMI are masked by the CPU.

Setting the  $\overline{RES}$  pin level low cancels sleep mode and selects the reset state. After the oscillation stabilization time has passed, driving the  $\overline{RES}$  pin high causes the CPU to start reset exception handling.

When the  $\overline{STBY}$  pin level is driven low, sleep mode is released and a transition is made to hardware standby mode.

## 18.5 Software Standby Mode

The CPU makes a transition to software standby mode when the SLEEP instruction is executed while the SSBY bit in SBYCR is set to 1, the LSON bit in LPWRCR is cleared to 0, and the PSS bit in TCSR (WDT\_1) is cleared to 0.

In software standby mode, the CPU, on-chip peripheral modules, and clock pulse generator all stop. However, the contents of the CPU's internal registers, on-chip RAM data, and the states of I/O ports and on-chip peripheral modules other than the SCI and PWMX are retained as long as the prescribed voltage is supplied.

Software standby mode is cleared by an external interrupt (NMI, IRQ0 to IRQ2, IRQ6, or IRQ7), the  $\overline{\text{RES}}$  pin input, or  $\overline{\text{STBY}}$  pin input.

When an external interrupt request signal is input, system clock oscillation starts, and after the elapse of the time set in bits STS2 to STS0 in SBYCR, software standby mode is cleared, and interrupt exception handling is started. When clearing software standby mode with an IRQ0 to IRQ2, IRQ6, or IRQ7 interrupt, set the corresponding enable bit to 1 and ensure that no interrupt with a higher priority than interrupts IRQ0 to IRQ2, IRQ6, and IRQ7 is generated. Software standby mode cannot be cleared if an interrupt enable bit corresponding to an IRQ0 to IRQ2, IRQ6, or IRQ7 interrupt is cleared to 0 or if the interrupt has been masked on the CPU side.

When the  $\overline{RES}$  pin is driven low, system clock oscillation is started. At the same time as system clock oscillation starts, the system clock is supplied to the entire LSI. Note that the  $\overline{RES}$  pin must be held low until clock oscillation stabilizes. When the  $\overline{RES}$  pin goes high after clock oscillation stabilizes, the CPU begins reset exception handling.

When the STBY pin is driven low, software standby mode is released and a transition is made to hardware standby mode.

Figure 18.3 shows an example in which a transition is made to software standby mode at the falling edge of the NMI pin, and software standby mode is cleared at the rising edge of the NMI pin.

In this example, an NMI interrupt is accepted with the NMIEG bit in SYSCR cleared to 0 (falling edge specification), then the NMIEG bit is set to 1 (rising edge specification), the SSBY bit is set to 1, and a SLEEP instruction is executed, causing a transition to software standby mode.

Software standby mode is then cleared at the rising edge of the NMI pin.

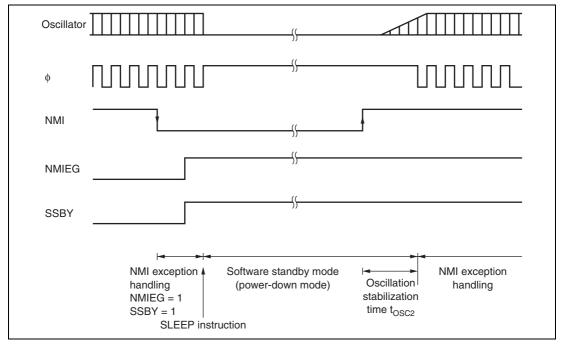

Figure 18.3 Application Example in Software Standby Mode

## 18.6 Hardware Standby Mode

The CPU makes a transition to hardware standby mode from any mode when the STBY pin is driven low.

In hardware standby mode, all functions enter the reset state. As long as the prescribed voltage is supplied, on-chip RAM data is retained. The I/O ports are set to the high-impedance state.

In order to retain on-chip RAM data, the RAME bit in SYSCR should be cleared to 0 before driving the  $\overline{STBY}$  pin low. Do not change the state of the mode pins (MD1 and MD0) while this LSI is in hardware standby mode.

Hardware standby mode is cleared by the STBY pin input or the RES pin input.

When the STBY pin is driven high while the RES pin is low, clock oscillation is started. Ensure that the  $\overline{RES}$  pin is held low until system clock oscillation stabilizes. When the  $\overline{RES}$  pin is subsequently driven high after the clock oscillation stabilization time has passed, reset exception handling starts.

Figure 18.4 shows an example of hardware standby mode timing.

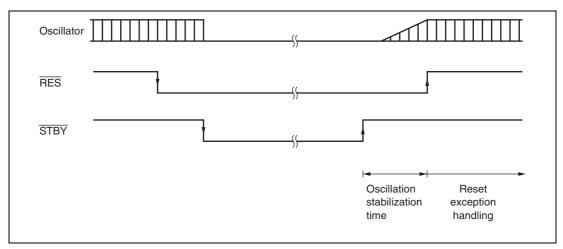

Figure 18.4 Hardware Standby Mode Timing

### 18.7 Watch Mode

The CPU makes a transition to watch mode when the SLEEP instruction is executed in high-speed mode or subactive mode with the SSBY bit in SBYCR set to 1, the DTON bit in LPWRCR cleared to 0, and the PSS bit in TCSR (WDT\_1) set to 1.

In watch mode, the CPU is stopped and peripheral modules other than WDT\_1 are also stopped. The contents of the CPU's internal registers, several on-chip peripheral module registers, and on-chip RAM data are retained and the I/O ports retain their values before transition as long as the prescribed voltage is supplied.

Watch mode is exited by an interrupt (WOVI1, NMI, IRQ0 to IRQ2, IRQ6, or IRQ7), RES pin input, or STBY pin input.

When an interrupt occurs, watch mode is exited and a transition is made to high-speed mode or medium-speed mode when the LSON bit in LPWRCR cleared to 0 or to subactive mode when the LSON bit is set to 1. When a transition is made to high-speed mode, a stable clock is supplied to the entire LSI and interrupt exception handling starts after the time set in the STS2 to STS0 bits in SBYCR has elapsed. In the case of an IRQ0 to IRQ2, IRQ6, or IRQ7 interrupt, watch mode is not exited if the corresponding enable bit has been cleared to 0. In the case of interrupts from the on-chip peripheral modules, watch mode is not exited if the interrupt enable register has been set to disable the reception of that interrupt, or the interrupt is masked by the CPU.

When the  $\overline{RES}$  pin is driven low, system clock oscillation starts. Simultaneously with the start of system clock oscillation, the system clock is supplied to the entire LSI. Note that the  $\overline{RES}$  pin must be held low until clock oscillation is stabilized. If the  $\overline{RES}$  pin is driven high after the clock oscillation stabilization time has passed, the CPU begins reset exception handling.

If the STBY pin is driven low, the LSI enters hardware standby mode.

## 18.8 Subsleep Mode

The CPU makes a transition to subsleep mode when the SLEEP instruction is executed in subactive mode with the SSBY bit in SBYCR cleared to 0, the LSON bit in LPWRCR set to 1, and the PSS bit in TCSR (WDT\_1) set to 1.

In subsleep mode, the CPU is stopped. Peripheral modules other than TMR\_0, TMR\_1, WDT\_0, and WDT\_1 are also stopped. The contents of the CPU's internal registers, several on-chip peripheral module registers, and on-chip RAM data are retained and the I/O ports retain their values before transition as long as the prescribed voltage is supplied.

Subsleep mode is exited by an interrupt (interrupts by on-chip peripheral modules, NMI, IRQ0 to IRQ7), the  $\overline{RES}$  pin input, or the  $\overline{STBY}$  pin input.

When an interrupt occurs, subsleep mode is exited and interrupt exception handling starts.

In the case of an IRQ0 to IRQ7 interrupt, subsleep mode is not exited if the corresponding enable bit has been cleared to 0. In the case of interrupts from the on-chip peripheral modules, subsleep mode is not exited if the interrupt enable register has been set to disable the reception of that interrupt, or the interrupt is masked by the CPU.

When the  $\overline{RES}$  pin is driven low, system clock oscillation starts. Simultaneously with the start of system clock oscillation, the system clock is supplied to the entire LSI. Note that the  $\overline{RES}$  pin must be held low until clock oscillation is stabilized. If the  $\overline{RES}$  pin is driven high after the clock oscillation stabilization time has passed, the CPU begins reset exception handling.

If the STBY pin is driven low, the LSI enters hardware standby mode.

#### 18.9 Subactive Mode

The CPU makes a transition to subactive mode when the SLEEP instruction is executed in high-speed mode with the SSBY bit in SBYCR set to 1, the DTON bit and LSON bit in LPWRCR set to 1, and the PSS bit in TCSR (WDT\_1) set to 1. When an interrupt occurs in watch mode, and if the LSON bit in LPWRCR is 1, a direct transition is made to subactive mode. Similarly, if an interrupt occurs in subsleep mode, a transition is made to subactive mode.

In subactive mode, the CPU operates at a low speed based on the subclock and sequentially executes programs. Peripheral modules other than TMR\_0, TMR\_1, WDT\_0, and WDT\_1 are also stopped.

When operating the CPU in subactive mode, the SCK2 to SCK0 bits in SBYCR must be cleared to 0.

Subactive mode is exited by the SLEEP instruction, RES pin input, or STBY pin input.

When the SLEEP instruction is executed with the SSBY bit in SBYCR set to 1, the DTON bit in LPWRCR cleared to 0, and the PSS bit in TCSR (WDT\_1) set to 1, the CPU exits subactive mode and a transition is made to watch mode. When the SLEEP instruction is executed with the SSBY bit in SBYCR cleared to 0, the LSON bit in LPWRCR set to 1, and the PSS bit in TCSR (WDT\_1) set to 1, a transition is made to subsleep mode. When the SLEEP instruction is executed with the SSBY bit in SBYCR set to 1, the DTON bit and LSON bit in LPWRCR set to 10, and the PSS bit in TCSR (WDT\_1) set to 1, a direct transition is made to high-speed mode.

For details of direct transitions, see section 18.11, Direct Transitions.

When the  $\overline{RES}$  pin is driven low, system clock oscillation starts. Simultaneously with the start of system clock oscillation, the system clock is supplied to the entire LSI. Note that the  $\overline{RES}$  pin must be held low until the clock oscillation is stabilized. If the  $\overline{RES}$  pin is driven high after the clock oscillation stabilization time has passed, the CPU begins reset exception handling.

If the STBY pin is driven low, the LSI enters hardware standby mode.

### 18.10 Module Stop Mode

Module stop mode can be individually set for each on-chip peripheral module.

When the corresponding MSTP bit in MSTPCR is set to 1, module operation stops at the end of the bus cycle and a transition is made to module stop mode. In turn, when the corresponding MSTP bit is cleared to 0, module stop mode is released and the module operation resumes at the end of the bus cycle. In module stop mode, the internal states of modules other than the SCI, D/A converter, A/D converter, and PWMX are retained.

After the reset state is released, all modules are in module stop mode.

While an on-chip peripheral module is in module stop mode, read/write access to its registers is disabled.

### 18.11 Direct Transitions

The CPU executes programs in three modes: high-speed, medium-speed, and subactive. When a direct transition is made from high-speed mode to subactive mode, there is no interruption of program execution. A direct transition is enabled by setting the DTON bit in LPWRCR to 1 and then executing the SLEEP instruction. After a transition, direct transition exception handling starts.

The CPU makes a transition to subactive mode when the SLEEP instruction is executed in high-speed mode with the SSBY bit in SBYCR set to 1, the LSON bit and DTON bit in LPWRCR set to 11, and the PSS bit in TSCR (WDT\_1) set to 1.

To make a direct transition to high-speed mode after the time set in the STS2 to STS0 bits in SBYCR has elapsed, execute the SLEEP instruction in subactive mode with the SSBY bit in SBYCR set to 1, the LSON bit and DTON bit in LPWRCR set to 01, and the PSS bit in TSCR (WDT\_1) set to 1.

## 18.12 Usage Notes

### **18.12.1 I/O Port Status**

The status of the I/O ports is retained in software standby mode. Therefore, when a high level is output, the current consumption is not reduced by the amount of current to support the high level output.

## 18.12.2 Current Consumption while Waiting for Oscillation to be Stabilized

The current consumption while waiting for oscillation to be stabilized is higher than that while oscillation is stabilized.

# Section 19 List of Registers

The register list gives information on the on-chip I/O register addresses, how the register bits are configured, and the register states in each operating mode. The information is given as shown below.

- 1. Register Addresses (address order)
- Registers are listed from the lower allocation addresses.
- The MSB-side address is indicated for 16-bit addresses.
- Registers are classified by functional modules.
- The access size is indicated.
- 2. Register Bits
- Bit configurations of the registers are described in the same order as the Register Addresses (address order) above.
- Reserved bits are indicated by in the bit name column.
- The bit number in the bit-name column indicates that the whole register is allocated as a counter or for holding data.
- 16-bit registers are indicated from the bit on the MSB side.
- 3. Register States in Each Operating Mode
- Register states are described in the same order as the Register Addresses (address order) above.
- The register states described here are for the basic operating modes. If there is a specific reset for an on-chip peripheral module, refer to the section on that on-chip peripheral module.
- 4. Register Select Conditions
- Register states are described in the same order as the Register Addresses (address order) above.
- For details on the register select conditions, refer to section 3.2.2, System Control Register (SYSCR), 3.2.3, Serial Timer Control Register (STCR), 18.1.3, Module Stop Control Registers H, L (MSTPCRH, MSTPCRL), and the register descriptions for each module.

# 19.1 Register Addresses (Address Order)

The data bus width indicates the numbers of bits by which the register is accessed.

The number of access states indicates the number of states based on the specified reference clock.

Register Name	Abbreviation	Number of Bits	Address	Module	Data Bus Width	Number of Access States
Keyboard comparator control register	KBCOMP	8	H'FEE4	IrDA/ Extended A/D	8	2
Interrupt control register A	ICRA	8	H'FEE8	INT	8	2
Interrupt control register B	ICRB	8	H'FEE9	INT	8	2
Interrupt control register C	ICRC	8	H'FEEA	INT	8	2
IRQ status register	ISR	8	H'FEEB	INT	8	2
IRQ sense control register H	ISCRH	8	H'FEEC	INT	8	2
IRQ sense control register L	ISCRL	8	H'FEED	INT	8	2
Address break control register	ABRKCR	8	H'FEF4	INT	8	2
Break address register A	BARA	8	H'FEF5	INT	8	2
Break address register B	BARB	8	H'FEF6	INT	8	2
Break address register C	BARC	8	H'FEF7	INT	8	2
Flash memory control register 1	FLMCR1	8	H'FF80	FLASH	8	2
Flash memory control register 2	FLMCR2	8	H'FF81	FLASH	8	2

# Section 20 Electrical Characteristics

### 20.1 Electrical Characteristics of H8S/2144B

### 20.1.1 Absolute Maximum Ratings

Table 20.1 lists the absolute maximum ratings.

**Table 20.1 Absolute Maximum Ratings** 

Note:

Item	Symbol	Value	Unit
Power supply voltage	V <sub>cc</sub>	-0.3 to +7.3	V
I/O buffer power supply voltage (port A)	V <sub>cc</sub> B	-0.3 to +7.0	V
Power supply (VCL input)*	V <sub>CL</sub>	-0.3 to +4.3	V
Input voltage (other than ports 6, 7, and A)	V <sub>in</sub>	$-0.3$ to $V_{cc}$ +0.3	V
Input voltage (CIN input not selected for port 6)	V <sub>in</sub>	$-0.3$ to $V_{cc}$ +0.3	V
Input voltage (CIN input not selected for port A)	V <sub>in</sub>	–0.3 to V <sub>cc</sub> B +0.3	V
Input voltage (CIN input selected for port 6)	V <sub>in</sub>	$-0.3$ V to lower of voltages $V_{cc}$ + 0.3 and $AV_{cc}$ + 0.3	V
Input voltage (CIN input selected for port A)	V <sub>in</sub>	$-0.3$ V to lower of voltages $V_{cc}B + 0.3$ and $AV_{cc} + 0.3$	V
Input voltage (port 7)	V <sub>in</sub>	-0.3 to AV <sub>cc</sub> + 0.3	V
Reference supply voltage	$AV_{ref}$	-0.3 to AV <sub>cc</sub> + 0.3	V
Analog power supply voltage	AV <sub>cc</sub>	-0.3 to +7.0	V
Analog input voltage	$V_{_{AN}}$	-0.3 to AV <sub>cc</sub> + 0.3	V
Operating temperature	T <sub>opr</sub>	General specifications: –20 to +75	°C
		Wide temperature range specifications: -40 to +85	
Operating temperature (flash memory programming/erasing)	$T_{opr}$	General specifications: –20 to +75	°C
		Wide temperature range specifications: -40 to +85	
Storage temperature	T <sub>stg</sub>	-55 to +125	°C

Caution: Operating this LSI in excess of the absolute maximum ratings may result in permanent damage.

Do not apply a voltage exceeding 7.0 V to input pins for the 5-V/4-V operation products.

Power supply pin for the internal power supply. Do not apply a power to the VCL pin for the 5-V/4-V operation products. Connect a capacitor for regulating the internal power voltage between the VCL and GND pins.

### 20.1.2 DC Characteristics

Table 20.2 lists the DC characteristics. Permissible output current values and bus driving characteristics are shown in tables 20.3 and 20.4, respectively.

## Table 20.2 DC Characteristics (1)

Conditions: 
$$V_{cc} = 5.0 \text{ V} \pm 10\%$$
,  $V_{cc}B = 5.0 \text{ V} \pm 10\%$ ,  $AV_{cc}^{*1} = 5.0 \text{ V} \pm 10\%$ ,  $AV_{ref}^{*1} = 4.5 \text{ V}$  to  $AV_{cc}$ ,  $V_{ss} = AV_{ss}^{*1} = 0 \text{ V}$ ,  $T_a = -20$  to  $+75^{\circ}\text{C}$  (General specifications),  $T_a = -40$  to  $+85^{\circ}\text{C}$  (Wide temperature range specifications)

  - 4. The port A characteristics depend on  $\rm V_{cc}B,$  and the characteristics for other pins depend on  $\rm V_{cc}.$

## **Table 20.3 Permissible Output Currents**

Conditions:  $V_{cc} = 4.0 \text{ V}$  to 5.5 V,  $V_{cc}B = 4.0 \text{ V}$  to 5.5 V,  $V_{ss} = 0 \text{ V}$ ,

 $T_a = -20$  to +75°C (General specifications),  $T_a = -40$  to +85°C (Wide temperature

range specifications)

Item		Symbol	Min.	Тур.	Max.	Unit
Permissible output low current (per pin)	PA7 to PA4 (bus driving function selected)	I <sub>OL</sub>	_	_	20	mA
	Ports 1 to 3	<del></del>	_	_	10	
	RESO	_	_	_	3	
	Other output pins	_	_	_	2	
Permissible output	Total of ports 1 to 3	$\Sigma$ I <sub>OL</sub>	_	_	80	mA
low current (total)	Total of all output pins, including the above		_	_	120	_
Permissible output high current (per pin)	All output pins	-I <sub>он</sub>	_	_	2	mA
Permissible output high current (total)	Total of all output pins	$\Sigma - I_{OH}$	_	_	40	mA

Notes: 1. To ensure reliability, do not exceed the output current values in table 20.3.

2. When driving a Darlington pair or LED, always insert a current-limiting resistor in the output line, as shown in figures 20.1 and 20.2.

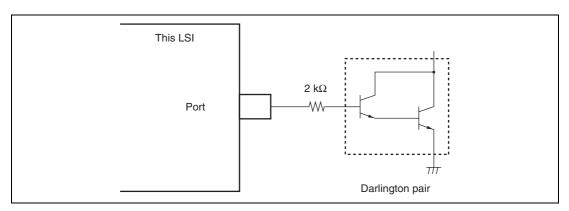

Figure 20.1 Darlington Pair Driving Circuit (Example)

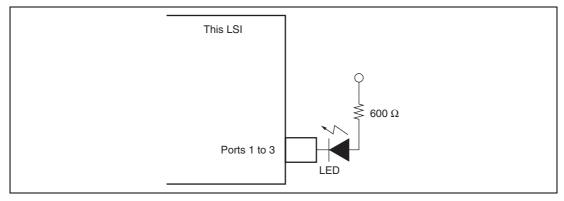

Figure 20.2 LED Driving Circuit (Example)

## **Table 20.4 Bus Driving Characteristics**

Conditions:  $V_{cc}B = 4.0 \text{ V} \text{ to } 5.5 \text{ V}, V_{ss} = 0 \text{ V}$ 

Applicable Pins: PA7 to PA4 (bus driving function selected)

Item	Symbol	Min.	Тур.	Max.	Unit	Test Conditions
Output low voltage	V <sub>oL</sub>	_	_	0.8	V	$I_{OL} = 16 \text{ mA}, V_{CC}B = 4.5 \text{ V to } 5.5 \text{ V}$
		_	_	0.5		I <sub>OL</sub> = 8 mA
		_	_	0.4		I <sub>OL</sub> = 3 mA

#### 20.1.3 AC Characteristics

Figure 20.3 shows the test conditions for the AC characteristics.

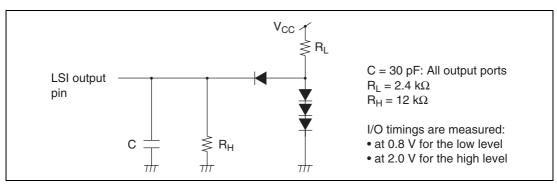

Figure 20.3 Output Load Circuit

**Clock Timing:** Table 20.5 shows the clock timing. The clock timing specified here covers clock (φ) output and oscillation stabilization times of the clock pulse generator (crystal) and external clock input (the EXTAL pin). For details on external clock input (the EXTAL pin and EXCL pin) timing, see section 17, Clock Pulse Generator.

#### Table 20.5 Clock Timing

Condition A:  $V_{cc} = 5.0 \text{ V} \pm 10\%$ ,  $V_{cc}B = 5.0 \text{ V} \pm 10\%$ ,  $V_{ss} = 0 \text{ V}$ ,  $\phi = 2 \text{ MHz}$  to maximum operating frequency,  $T_a = -20$  to  $+75^{\circ}$ C (General specifications),  $T_a = -40$  to  $+85^{\circ}$ C (Wide temperature range specifications)

Condition B:  $V_{cc} = 4.0 \text{ V}$  to 5.5 V,  $V_{cc}B = 4.0 \text{ V}$  to 5.5 V,  $V_{ss} = 0 \text{ V}$ ,  $\phi = 2 \text{ MHz}$  to maximum operating frequency,  $T_a = -20 \text{ to } +75^{\circ}\text{C}$  (General specifications),  $T_a = -40 \text{ to } +85^{\circ}\text{C}$  (Wide temperature range specifications)

**Timing of On-Chip Peripheral Modules:** Tables 20.8 shows the on-chip peripheral module timing. The only on-chip peripheral modules that can operate during this LSI operating on the subclock ( $\phi = 32.768 \text{ kHz}$ ) are the I/O ports, external interrupts (NMI, IRQ0, IRQ1, IRQ2, IRQ6, and IRQ7), watchdog timer, and the 8-bit timer (channels 0 and 1).

## **Table 20.8 Timing of On-Chip Peripheral Modules**

Condition A:  $V_{cc} = 5.0 \text{ V} \pm 10\%$ ,  $V_{cc}B = 5.0 \text{ V} \pm 10\%$ ,  $V_{ss} = 0 \text{ V}$ ,  $\phi = 32.768 \text{ kHz*}$  or 2 MHz to maximum operating frequency,  $T_a = -20 \text{ to } +75^{\circ}\text{C}$  (General specifications),  $T_a = -40 \text{ to } +85^{\circ}\text{C}$  (Wide temperature range specifications)

Condition B:  $V_{cc}$  = 4.0 V to 5.5 V,  $V_{cc}B$  = 4.0 V to 5.5 V,  $V_{ss}$  = 0 V,  $\phi$  = 32.768 kHz\* or 2 MHz to maximum operating frequency,  $T_a$  = -20 to +75°C (General specifications),  $T_a$  = -40 to +85°C (Wide temperature range specifications)

	Wait time after setting PV bit *1	γ	4	_	_	μs	
	Wait time after dummy write*1	ε	2	_	_	μs	
	Wait time after clearing PV bit *1	η	2	_	_	μs	
	Wait time after clearing SWE bit *1	θ	100	_	_	μs	
	Maximum programming count* <sup>1</sup> * <sup>4</sup> * <sup>5</sup>	N	_	_	1000	times	

	Item	Symbol	Min.	Тур.	Max.	Unit	Test Conditions
Erasure	Wait time after setting SWE bit*1	х	1		_	μs	
	Wait time after setting ESU bit*1	у	100	_	_	μs	
	Wait time after setting E bit*1*6	Z	10	_	100	ms	
	Wait time after clearing E bit*1	α	10	_	_	μs	
	Wait time after clearing ESU bit*1	β	10	_	_	μs	
	Wait time after setting EV bit*1	γ	20	_	_	μs	
	Wait time after dummy-writing H'FF* <sup>1</sup>	ε	2	_	_	μs	
	Wait time after clearing EV bit*1	η	4	_	_	μs	
	Wait time after clearing SWE bit*1	θ	100	_	_	μs	
	Maximum erasure count*1*6*7	N	_	_	120	times	

Notes: 1. Set the times according to the programming/erasing algorithms.

- 2. Programming time per 128 bytes (Shows the total period for which the P bit in FLMCR1 is set. It does not include the programming-verifying time.)
- 3. Block erasing time (Shows the total period for which the E bit in FLMCR1 is set. It does not include the erasing-verifying time.)
- 4. Maximum programming time (t<sub>P</sub> (max.))

 $t_P$  (max.) = (wait time after setting P bit (z1) + (z3)) × 6

+ wait time after setting P bit  $(z2) \times ((N) - 6)$ 

5. The maximum programming court (N) should be set according to the actual set value of z1, z2 and z3 to allow programming within the maximum programming time  $(t_{_{\rm P}}(max.))$ .

The wait time after setting the P bit (z1, z2, and z3) should be alternated according to the programming count (n) as follows:

 $1 \le n \le 6$   $z1 = 30\mu s, z3 = 10\mu s$ 

 $7 \le n \le 1000$   $z2 = 200 \mu s$ 

6. Maximum erasure time (t<sub>F</sub> (max.))

 $t_{_E}$  (max.) = Wait time after setting E bit (z)  $\times$  maximum erasure count (N)

 The maximum erasure count (N) should be set according to the actual set value of z to allow erasing within the maximum erasure time (t<sub>F</sub> (max.)).

## 20.1.7 Usage Note

• LSI with Internal Step-Down Circuit

This LSI includes an internal step-down circuit which automatically step down the internal power voltage to an appropriate level.

A capacitor or capacitors for regulating the internal power voltage (one 0.47- $\mu F$  capacitor or two 0.47- $\mu F$  capacitors in parallel) must be placed between the internal step-down and VSS pins.

For connection of the capacitor, see figure 20.26.

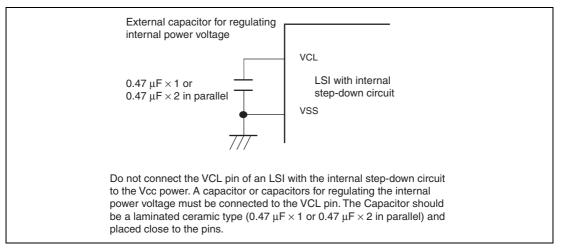

Figure 20.26 Connection of VCL Capacitor

## 20.2 Electrical Characteristics of H8S/2134B

## 20.2.1 Absolute Maximum Ratings

Table 20.13 lists the absolute maximum ratings.

**Table 20.13 Absolute Maximum Ratings** 

Item	Symbol	Value	Unit
Power supply voltage	V <sub>cc</sub>	-0.3 to +7.3	V
Power supply (VCL input)*	V <sub>CL</sub>	-0.3 to +4.3	V
Input voltage (other than ports 6 and 7)	V <sub>in</sub>	$-0.3$ to $V_{cc} + 0.3$	V
Input voltage (CIN input not selected for port 6)	V <sub>in</sub>	$-0.3$ to $V_{cc} + 0.3$	V
Input voltage (CIN input selected for port 6)	V <sub>in</sub>	$-0.3$ V to lower of voltages $V_{cc}$ + 0.3 and $AV_{cc}$ + 0.3	V
Input voltage (port 7)	$V_{in}$	-0.3 to AV <sub>cc</sub> + 0.3	V
Analog power supply voltage	AV <sub>cc</sub>	-0.3 to +7.0	V
Analog input voltage	$V_{AN}$	-0.3 to AV <sub>cc</sub> + 0.3	V
Operating temperature	T <sub>opr</sub>	General specifications: -20 to +75	°C
		Wide temperature range specifications: -40 to +85	
Operating temperature (flash memory programming/erasing)	T <sub>opr</sub>	General specifications: -20 to +75	°C
		Wide temperature range specifications: -40 to +85	
Storage temperature	T <sub>stg</sub>	-55 to +125	°C

Caution: Operating this LSI in excess of the absolute maximum ratings may result in permanent damage.

Do not apply a voltage exceeding 7.0 V to input pins for the 5-V/4-V operation products.

Note: \* Power supply pin for the internal power supply. Do not apply a power to the VCL pin for the 5-V/4-V operation products. Connect a capacitor for regulating the internal power voltage between the VCL and GND pins.

#### 20.2.2 DC Characteristics

Table 20.14 lists the DC characteristics. Permissible output current values are shown in table 20.16.

# Table 20.14 DC Characteristics (1)

Conditions:  $V_{cc} = 5.0 \text{ V} \pm 10\%$ ,  $AV_{cc}^{*1} = 5.0 \text{ V} \pm 10\%$ ,  $V_{ss} = AV_{ss}^{*1} = 0 \text{ V}$ ,

 $T_a = -20$  to +75°C (General specifications),  $T_a = -40$  to +85°C (Wide temperature

range specifications)

ourront	Idle	=	_	0.01	5.0	μΑ	
Analog power	er supply voltage*1	AV <sub>cc</sub>	4.0	_	5.5	٧	Operating
			2.0		5.5	_	Idle/not used
RAM standb	y voltage	V <sub>RAM</sub>	2.0		_	٧	

Notes: 1. Do not leave the AV<sub>cc</sub> and AV<sub>ss</sub> pins open even if the A/D converter and D/A converter are not used.

Even if the A/D converter and D/A converter are not used, apply a voltage in the range from 2.0 V to 5.5 V by connecting the  $AV_{cc}$  pin to the power supply ( $V_{cc}$ ), or some other method.

- 2. Current consumption values are for  $V_{\text{\tiny IH}}$  min. =  $V_{\text{\tiny CC}}$  0.2 V and  $V_{\text{\tiny IL}}$  max. = 0.2 V with all output pins unloaded and the on-chip pull-up MOSs disabled.
- 3. The values are for  $V_{RAM} \le V_{CC} < 4.0 \text{ V}$ ,  $V_{IH}$  min. =  $V_{CC} 0.2 \text{ V}$  and  $V_{II}$  max. = 0.2 V.
- 4. The reference power supply current (Al $_{\rm ref}$ ) is added to the analog power supply current (Al $_{\rm cc}$ ).

# **Table 20.15 Permissible Output Currents**

Conditions:  $V_{cc} = 4.0 \text{ V}$  to 5.5 V,  $V_{ss} = 0 \text{ V}$ ,

 $T_a = -20 \text{ to } +75^{\circ}\text{C}$  (General specifications),  $T_a = -40 \text{ to } +85^{\circ}\text{C}$  (Wide temperature

range specifications)

Item		Symbol	Min.	Тур.	Max.	Unit
Permissible output	Ports 1 to 3	I <sub>OL</sub>	_	_	10	mA
low current (per pin)	Other output pins	<del>_</del>	_	_	2	
Permissible output	Total of ports 1 to 3	$\Sigma$ I <sub>OL</sub>	_	_	80	mA
low current (total)	Total of all output pins, including the above		_	_	120	_
Permissible output high current (per pin)	All output pins	<b>-I</b> <sub>OH</sub>	_	_	2	mA
Permissible output high current (total)	Total of all output pins	$\Sigma - I_{OH}$	_	_	40	mA

Notes: 1. To ensure reliability, do not exceed the output current values in table 20.3.

2. When driving a Darlington pair or LED, always insert a current-limiting resistor in the output line, as shown in figures 20.27 and 20.28.

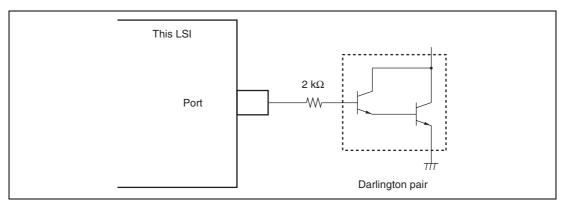

Figure 20.27 Darlington Pair Driving Circuit (Example)

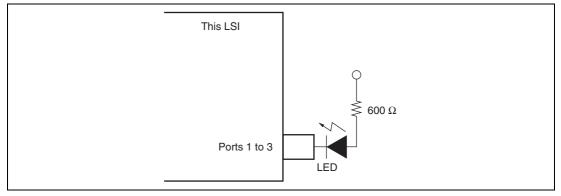

Figure 20.28 LED Driving Circuit (Example)

## 20.2.3 AC Characteristics

Figure 20.29 shows the test conditions for the AC characteristics.

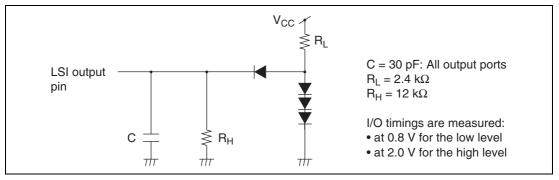

Figure 20.29 Output Load Circuit

**Clock Timing:** Table 20.16 shows the clock timing. The clock timing specified here covers clock (φ) output and oscillation stabilization times of the clock pulse generator (crystal) and external clock input (the EXTAL pin). For details on external clock input (the EXTAL pin and EXCL pin) timing, see section 17, Clock Pulse Generator.

## Table 20.16 Clock Timing

Condition A:  $V_{cc} = 5.0 \text{ V} \pm 10\%$ ,  $V_{ss} = 0 \text{ V}$ ,  $\phi = 2 \text{ MHz}$  to maximum operating frequency,  $T_a = -20 \text{ to } +75^{\circ}\text{C}$  (General specifications),  $T_a = -40 \text{ to } +85^{\circ}\text{C}$  (Wide temperature range specifications)

Condition B:  $V_{cc}$  = 4.0 V to 5.5 V,  $V_{ss}$  = 0 V,  $\phi$  = 2 MHz to maximum operating frequency,  $T_a$  = -20 to +75°C (General specifications),  $T_a$  = -40 to +85°C (Wide temperature range specifications)

	ltem	Symbol	Min.	Тур.	Max.	Unit	Test Conditions
Erasure	Wait time after setting SWE bit*1	х	1	_	_	μs	
	Wait time after setting ESU bit*1	У	100	_	_	μs	
	Wait time after setting E bit*1*6	Z	10	_	100	ms	
	Wait time after clearing E bit*1	α	10	_	_	μs	
	Wait time after clearing ESU bit*1	β	10	_	_	μs	
	Wait time after setting EV bit*1	γ	20	_	_	μs	
	Wait time after dummy-writing H'FF*1	ε	2	_	_	μs	
	Wait time after clearing EV bit*1	η	4	_	_	μs	
	Wait time after clearing SWE bit*1	θ	100	_	_	μs	
	Maximum erasure count*1*6*7	N	_	_	120	times	

Notes: 1. Set the times according to the programming/erasing algorithms.

- 2. Programming time per 128 bytes (Shows the total period for which the P bit in FLMCR1 is set. It does not include the programming-verifying time.)
- 3. Block erasing time (Shows the total period for which the E bit in FLMCR1 is set. It does not include the erasing-verifying time.)
- 4. Maximum programming time (t<sub>P</sub> (max.))
  - $t_{_{P}}$  (max.) = (wait time after setting P bit (z1) + (z3)) × 6
  - + wait time after setting P bit  $(z2) \times ((N) 6)$
- 5. The maximum programming court (N) should be set according to the actual set value of z1, z2 and z3 to allow programming within the maximum programming time  $(t_p \text{ (max.)})$ .

The wait time after setting the P bit (z1, z2, and z3) should be alternated according to the programming count (n) as follows:

$$1 \le n \le 6$$
  $z1 = 30\mu s, z3 = 10\mu s$ 

- $7 \le n \le 1000$   $z2 = 200 \mu s$
- 6. Maximum erasure time  $(t_{\rm E} (max.))$ 
  - $t_{_E}$  (max.) = Wait time after setting E bit (z)  $\times$  maximum erasure count (N)
- 7. The maximum erasure count (N) should be set according to the actual set value of z to allow erasing within the maximum erasure time (t<sub>F</sub> (max.)).

## 20.2.7 Usage Note

• LSI with Internal Step-Down Circuit

This LSI includes an internal step-down circuit which automatically step down the internal power voltage to an appropriate level.

A capacitor or capacitors for regulating the internal power voltage (one 0.47- $\mu F$  capacitor or two 0.47- $\mu F$  capacitors in parallel) must be placed between the internal step-down and VSS pins.

For connection of the capacitor, see figure 20.51.

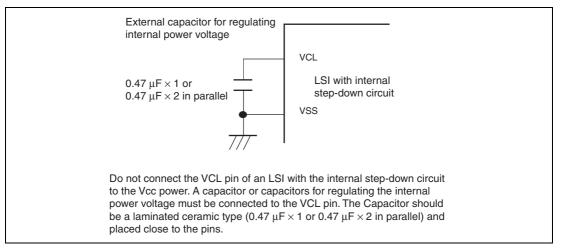

Figure 20.51 Connection of VCL Capacitor

# Appendix A I/O Port States in Each Processing State

Table A.1 I/O Port States in Each Processing State

Port Name Pin Name	MCU Operating Mode	Reset	Hardware Standby Mode	Software Standby Mode	Watch Mode	Sleep Mode	Sub- sleep Mode	Subactive Mode	Program Execution State
Port 1	1	L	T	kept*1	kept*1	kept*1	kept*1	A7 to A0	A7 to A0
A7 to A0	2, 3 (EXPE = 1)	T						Address output/ input port	Address output/ input port

	2, 3 (EXPE = 0)			kept	kept	kept	kept	I/O port	I/O port

# [Legend]

H: High L: Low

T: High-impedance state

kept: Input ports are in the high-impedance state (when DDR = 0 and PCR = 1, input pull-up MOSs remain on).

Output ports maintain their previous state.

Depending on the pins, the on-chip peripheral modules may be initialized and the I/O port function determined by DDR and DR used.

DDR: Data direction register

Notes: 1. When the address output is selected, the previous address accessed is retained.

- 2. This signal is for the H8S/2144B and is not available for the H8S/2134B.
- 3. These signal names are for the H8S/2144B. D7 to D0 are used for the H8S/2134B.
- 4. This signal name is for the H8S/2144B. WR is used for the H8S/2134B.

# Appendix B Product Codes

Product Typ	oe e	Product Code	Mark Code	Package (Code)
H8S/2144B	Flash memory version	HD64F2144B	F2144BFA20	100-pin QFP (FP-100B)
			F2144BTE20	100-pin TQFP (TFP-100B)
H8S/2134B	Flash memory version	HD64F2134B	F2134BFA20	80-pin QFP (FP-80B)
			F2134BTE20	80-pin TQFP (TFP-80B)

Note: \* Some products above are in the developing or planning stage. Please contact Renesas agency to conform the present status of each product.
