

FEATURES

Bias voltage range (VBIAS): 2.5 V to 5.5 V
LDO input voltage range (VIN1/VIN2, VIN3): 1.8 V to 5.5 V
Three 200 mA low dropout voltage regulators
16-lead, 3 mm × 3 mm LFCSP
Initial accuracy: ±1%
Stable with 1 μF ceramic output capacitors
No noise bypass capacitor required
3 independent logic controlled enables
Over current and thermal protection

Key specifications

High PSRR

76 dB PSRR up to 1 kHz
70 dB PSRR 10 kHz
60 dB PSRR at 100 kHz
40 dB PSRR at 1 MHz

Low output noise

29 μV rms typical output noise at V_{OUT} = 1.2 V
55 μV rms typical output noise at V_{OUT} = 2.8 V

Excellent transient response

Low dropout voltage: 110 mV @ 200 mA load
85 μA typical ground current at no load, all LDOs enabled
100 μs fast turn-on circuit
Guaranteed 200 mA output current per regulator
−40°C to +125°C junction temperature

APPLICATIONS

Mobile phones
Digital cameras and audio devices
Portable and battery-powered equipment
Portable medical devices
Post dc-to-dc regulation

GENERAL DESCRIPTION

The ADP320 200 mA triple output LDO combines high PSRR, low noise, low quiescent current, and low dropout voltage in a voltage regulator ideally suited for wireless applications with demanding performance and board space requirements.

The low quiescent current, low dropout voltage, and wide input voltage range of the ADP320 triple LDO extend the battery life of portable devices. The ADP320 triple LDO maintains power supply rejection greater than 60 dB for frequencies as high as 100 kHz while operating with a low headroom voltage. The ADP320 triple

TYPICAL APPLICATION CIRCUITS

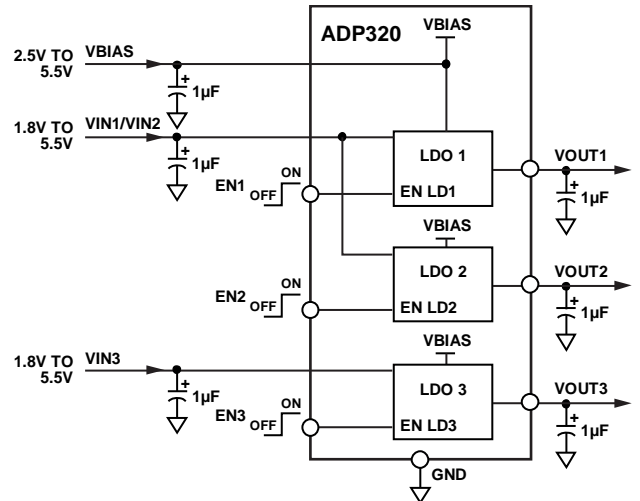

Figure 1. Typical Application Circuit

02838-001

LDO offers much lower noise performance than competing LDOs without the need for a noise bypass capacitor.

The ADP320 triple LDO is available in a miniature 16-lead 3 mm × 3 mm LFCSP package and is stable with tiny 1 μF ±30% ceramic output capacitors, resulting in the smallest possible board area for a wide variety of portable power needs.

The ADP320 triple LDO is available in output voltage combinations ranging from 0.8 V to 3.3 V and offers over current and thermal protection to prevent damage in adverse conditions.

¹ Based on an end-point calculation using 1 mA and 200 mA loads.

² Dropout voltage is defined as the input-to-output voltage differential when the input voltage is set to the nominal output voltage. This applies only for output voltages above 1.8 V.

³ Start-up time is defined as the time between the rising edge of ENx to V_{OUTx} being at 90% of its nominal value.

⁴ Current-limit threshold is defined as the current at which the output voltage drops to 90% of the specified typical value. For example, the current limit for a 3.0 V output voltage is defined as the current that causes the output voltage to drop to 90% of 3.0 V, or 2.7 V.

INPUT AND OUTPUT CAPACITOR, RECOMMENDED SPECIFICATIONS

Table 2.

Parameter	Symbol	Conditions	Min	Typ	Max	Unit
MINIMUM INPUT AND OUTPUT CAPACITANCE ¹	C_{MIN}	$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$	0.70			μF
CAPACITOR ESR	R_{ESR}	$T_A = -40^\circ\text{C}$ to $+125^\circ\text{C}$	0.001		1	Ω

¹ The minimum input and output capacitance should be greater than 0.70 μF over the full range of operating conditions. The full range of operating conditions in the application must be considered during device selection to ensure that the minimum capacitance specification is met. X7R and X5R type capacitors are recommended, Y5V and Z5U capacitors are not recommended for use with LDOs.

ABSOLUTE MAXIMUM RATINGS

Table 3.

Parameter	Rating
VIN1/VIN2, VIN3, VBIAS to GND	–0.3 V to +6.5 V
VOUT1, VOUT2 to GND	–0.3 V to VIN1/VIN2
VOUT3 to GND	–0.3 V to VIN3
EN1, EN2, EN3 to GND	–0.3 V to +6.5 V
Storage Temperature Range	–65°C to +150°C
Operating Junction Temperature Range	–40°C to +125°C
Soldering Conditions	JEDEC J-STD-020

Stresses above those listed under absolute maximum ratings may cause permanent damage to the device. This is a stress rating only and functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

THERMAL DATA

Absolute maximum ratings apply individually only, not in combination.

The ADP320 triple LDO can be damaged when the junction temperature limits are exceeded. Monitoring ambient temperature does not guarantee that the junction temperature (T_J) is within the specified temperature limits. In applications with high power dissipation and poor thermal resistance the maximum ambient temperature may have to be derated. In applications with moderate power dissipation and low PCB thermal resistance, the maximum ambient temperature can exceed the maximum limit as long as the junction temperature is within specification limits.

The junction temperature (T_J) of the device is dependent on the ambient temperature (T_A), the power dissipation of the device (P_D), and the junction-to-ambient thermal resistance of the package (θ_{JA}). Maximum junction temperature (T_J) is calculated from the ambient temperature (T_A) and power dissipation (P_D) using the following formula:

$$T_J = T_A + (P_D \times \theta_{JA})$$

Junction-to-ambient thermal resistance (θ_{JA}) of the package is based on modeling and calculation using a 4-layer board. The junction-to-ambient thermal resistance is highly dependent on the application and board layout. In applications where high maximum power dissipation exists, close attention to thermal board design is required. The value of θ_{JA} may vary, depending on PCB material, layout, and environmental conditions. The specified values of θ_{JA} are based on a four-layer, 4-inch \times 3-inch circuit board. Refer to JEDEC JESD 51-9 for detailed information on the board construction. For additional information, see the AN-617 Application Note, *MicroCSP™ Wafer Level Chip Scale Package*.

Ψ_{JB} is the junction to board thermal characterization parameter with units of °C/W. Ψ_{JB} of the package is based on modeling and calculation using a 4-layer board. The JESD51-12, *Guidelines for Reporting and Using Package Thermal Information*, states that thermal characterization parameters are not the same as thermal resistances. Ψ_{JB} measures the component power flowing through multiple thermal paths rather than a single path as in thermal resistance, θ_{JB} . Therefore, Ψ_{JB} thermal paths include convection from the top of the package as well as radiation from the package; factors that make Ψ_{JB} more useful in real-world applications. Maximum junction temperature (T_J) is calculated from the board temperature (T_B) and power dissipation (P_D) using the following formula

$$T_J = T_B + (P_D \times \Psi_{JB})$$

Refer to JEDEC JESD51-8 and JESD51-12 for more detailed information about Ψ_{JB} .

THERMAL RESISTANCE

θ_{JA} and Ψ_{JB} are specified for the worst-case conditions, that is, a device soldered in a circuit board for surface-mount packages.

Table 4.

Package Type	θ_{JA}	Ψ_{JB}	Unit
16-Lead 3 mm \times 3 mm LFCSP	49.5	25.2	°C/W

ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

PIN CONFIGURATIONS AND FUNCTION DESCRIPTIONS

NOTES

1. NC = NO CONNECT.

Figure 2. Pin Configuration

Table 5. Pin Function Descriptions

Pin No.	Mnemonic	Description
1	EN1	Enable Input for Regulator 1. Drive EN1 high to turn on Regulator 1; drive it low to turn off Regulator 1. For automatic startup, connect EN1 to VBIAS.
2	VBIAS	Input Voltage Bias Supply. Bypass VBIAS to GND with a 1 μ F or greater capacitor.
3	VIN1/VIN2	Regulator Input Supply for Output Voltage 1 and Output Voltage 2. Bypass VIN1/VIN2 to GND with a 1 μ F or greater capacitor.
4	VIN1/VIN2	Regulator Input Supply for Output Voltage 1 and Output Voltage 2. Bypass VIN1/VIN2 to GND with a 1 μ F or greater capacitor.
5	VOUT1	Regulated Output Voltage 1. Connect a 1 μ F or greater output capacitor between VOUT1 and GND.
6	VOUT2	Regulated Output Voltage 2. Connect a 1 μ F or greater output capacitor between VOUT2 and GND.
7	VOUT3	Regulated Output Voltage 3. Connect a 1 μ F or greater output capacitor between VOUT3 and GND.
8	NC	Not connected internally.
9	VIN3	Regulator Input Supply for Output Voltage 3. Bypass VIN3 to GND with a 1 μ F or greater capacitor.
10	VIN3	Regulator Input Supply for Output Voltage 3. Bypass VIN3 to GND with a 1 μ F or greater capacitor.
11	GND	Ground Pin.
12	GND	Ground Pin.
13	NC	Not connected internally.
14	NC	Not connected internally.
15	EN3	Enable Input for Regulator 3. Drive EN3 high to turn on Regulator 3; drive it low to turn off Regulator 3. For automatic startup, connect EN3 to VBIAS.
16	EN2	Enable Input for Regulator 2. Drive EN2 high to turn on Regulator 2; drive it low to turn off Regulator 2. For automatic startup, connect EN2 to VBIAS.
EP	EP	Exposed pad for enhanced thermal performance. Connect to copper ground plane.

THEORY OF OPERATION

The ADP320 triple LDO is a low quiescent current, low dropout linear regulator that operates from 1.8 V to 5.5 V on VIN1/VIN2 and VIN3 and provides up to 200 mA of current from each output. Drawing a low 250 μ A quiescent current (typical) at full load makes the ADP320 triple LDO ideal for battery-operated portable equipment. Shutdown current consumption is typically 100 nA.

Optimized for use with small 1 μ F ceramic capacitors, the ADP320 triple LDO provides excellent transient performance.

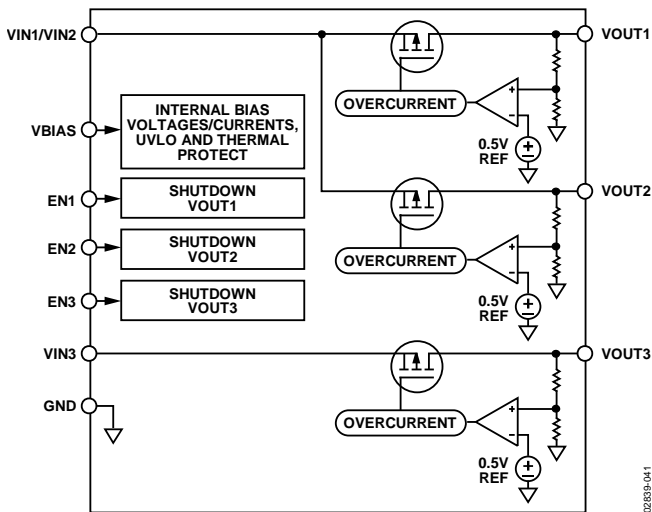

Figure 41. Internal Block Diagram

Internally, the ADP320 triple LDO consist of a reference, three error amplifiers, three feedback voltage dividers, and three PMOS pass transistors. Output current is delivered via the PMOS pass device, which is controlled by the error amplifier. The error amplifier compares the reference voltage with the feedback voltage from the output and amplifies the difference. If the feedback voltage is lower than the reference voltage, the gate of the PMOS device is pulled lower, allowing more current to flow and increasing the output voltage. If the feedback voltage is higher than the reference voltage, the gate of the PMOS device is pulled higher, allowing less current to flow and decreasing the output voltage.

The ADP320 triple LDO is available in multiple output voltage options ranging from 0.8 V to 3.3 V. The ADP320 triple LDO uses the EN1, EN2, and EN3 enable pins to enable and disable the VOUT1/VOUT2/VOUT3 pins under normal operating conditions. When the enable pins are high, VOUT1/VOUT2/VOUT3 turn on; when enable pins are low, VOUT1/VOUT2/VOUT3 turn off. For automatic startup, the enable pins can be tied to VBIAS.

APPLICATIONS INFORMATION

CAPACITOR SELECTION

Output Capacitor

The ADP320 triple LDO is designed for operation with small, space-saving ceramic capacitors, but the parts function with most commonly used capacitors as long as care is taken in regards to the effective series resistance (ESR) value. The ESR of the output capacitor affects stability of the LDO control loop. A minimum of $0.70 \mu\text{F}$ capacitance with an ESR of 1Ω or less is recommended to ensure stability of the ADP320 triple LDO. Transient response to changes in load current is also affected by output capacitance. Using a larger value of output capacitance improves the transient response of the ADP320 triple LDO to large changes in the load current. Figure 42 show the transient response for an output capacitance value of $1 \mu\text{F}$.

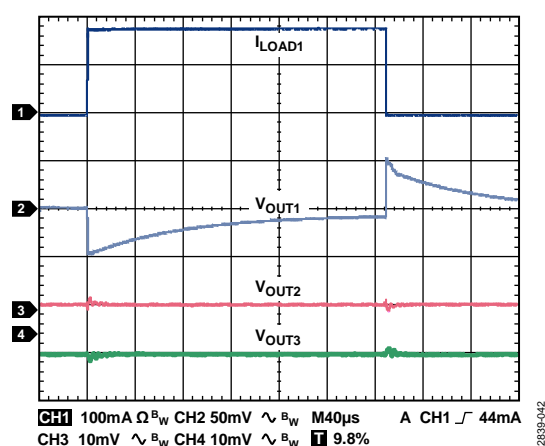

Figure 42. Output Transient Response,
 $I_{LOAD1} = 1 \text{ mA}$ to 200 mA , $I_{LOAD2} = 1 \text{ mA}$, $I_{LOAD3} = 1 \text{ mA}$,
 $CH1 = I_{LOAD1}$, $CH2 = V_{OUT1}$, $CH3 = V_{OUT2}$, $CH4 = V_{OUT3}$

Input Bypass Capacitor

Connecting a $1 \mu\text{F}$ capacitor from VIN1/VIN2, VIN3, and VBIAS to GND reduces the circuit sensitivity to the PCB layout, especially when long input traces or high source impedance are encountered. If an output capacitance greater than $1 \mu\text{F}$ is required, the input capacitor should be increased to match it.

Input and Output Capacitor Properties

Any good quality ceramic capacitor may be used with the ADP320 triple LDO, as long as the capacitor meets the minimum capacitance and maximum ESR requirements. Ceramic capacitors are manufactured with a variety of dielectrics, each with a different behavior over temperature and applied voltage. Capacitors must have an adequate dielectric to ensure the minimum capacitance over the necessary temperature range and dc bias conditions. X5R or X7R dielectrics with a voltage rating of 6.3 V or 10 V are recommended. Y5V and Z5U dielectrics are not recommended, due to their poor temperature and dc bias characteristics.

Figure 43 depicts the capacitance vs. voltage bias characteristic of an 0402 $1 \mu\text{F}$, 10 V , X5R capacitor. The voltage stability of a capacitor is strongly influenced by the capacitor size and voltage rating. In general, a capacitor in a larger package or higher voltage rating exhibits better stability. The temperature variation of the X5R dielectric is about $\pm 15\%$ over the -40°C to $+85^\circ\text{C}$ temperature range and is not a function of the package or voltage rating.

Figure 43. Capacitance vs. Voltage Bias Characteristic

ADP320

Use Equation 1 to determine the worst-case capacitance accounting for capacitor variation over temperature, component tolerance, and voltage.

$$C_{EFF} = C_{BIAS} \times (1 - TEMP_{CO}) \times (1 - TOL) \quad (1)$$

where:

C_{BIAS} is the effective capacitance at the operating voltage.
 $TEMP_{CO}$ is the worst-case capacitor temperature coefficient.
 TOL is the worst-case component tolerance.

In this example, $TEMP_{CO}$ over -40°C to $+85^{\circ}\text{C}$ is assumed to be 15% for an X5R dielectric. TOL is assumed to be 10%, and C_{BIAS} is $0.94 \mu\text{F}$ at 1.8 V from the graph in Figure 43.

Substituting these values into Equation 1 yields

$$C_{EFF} = 0.94 \mu\text{F} \times (1 - 0.15) \times (1 - 0.1) = 0.719 \mu\text{F}$$

Therefore, the capacitor chosen in this example meets the minimum capacitance requirement of the LDO over temperature and tolerance at the chosen output voltage.

To guarantee the performance of the ADP320 triple LDO, it is imperative that the effects of dc bias, temperature, and tolerances on the behavior of the capacitors are evaluated for each application.

UNDERVOLTAGE LOCKOUT

The ADP320 triple LDO has an internal undervoltage lockout circuit that disables all inputs and the output when the input voltage bias, V_{BIAS} , is less than approximately 2.2 V. This ensures that the inputs of the ADP320 triple LDO and the output behave in a predictable manner during power-up.

ENABLE FEATURE

The ADP320 triple LDO uses the EN_x pins to enable and disable the VO_{UTx} pins under normal operating conditions.

Figure 44 shows a rising voltage on EN crossing the active threshold, then VO_{UTx} turns on. When a falling voltage on EN_x crosses the inactive threshold, VO_{UTx} turns off.

Figure 44. Typical EN_x Pin Operation

As shown in

Figure 44, the EN_x pin has built-in hysteresis. This prevents on/off oscillations that can occur due to noise on the EN_x pin as it passes through the threshold points.

The active/inactive thresholds of the EN_x pin are derived from the V_{BIAS} voltage. Therefore, these thresholds vary with changing input voltage. Figure 45 shows typical EN_x active/inactive thresholds when the input voltage varies from 2.5 V to 5.5 V.

Figure 45. Typical EN_x Pins Thresholds vs. Input Voltage

The ADP320 triple LDO utilizes an internal soft start to limit the inrush current when the output is enabled. The start-up time for the 2.8 V option is approximately 220 μs from the time the EN_x active threshold is crossed to when the output reaches 90% of its final value. The start-up time is somewhat dependent on the output voltage setting and increases slightly as the output voltage increases.

Figure 46. Typical Start-Up Time,
 $I_{LOAD1} = I_{LOAD2} = I_{LOAD3} = 100 \text{ mA}$,
 $CH1 = V_{EN}$, $CH2 = V_{OUT1}$, $CH3 = V_{OUT2}$, $CH4 = V_{OUT3}$

CURRENT-LIMIT AND THERMAL OVERLOAD PROTECTION

The ADP320 triple LDO is protected against damage due to excessive power dissipation by current and thermal overload protection circuits. The ADP320 triple LDO is designed to current limit when the output load reaches 300 mA (typical). When the output load exceeds 300 mA, the output voltage is reduced to maintain a constant current limit.

Thermal overload protection is built-in, which limits the junction temperature to a maximum of 155°C (typical). Under extreme conditions (that is, high ambient temperature and power dissipation) when the junction temperature starts to rise above 155°C, the output is turned off, reducing the output current to zero. When the junction temperature drops below 140°C, the output is turned on again and the output current is restored to its nominal value.

Consider the case where a hard short from VOUTx to GND occurs. At first, the ADP320 triple LDO current limits, so that only 300 mA is conducted into the short. If self-heating of the junction is great enough to cause its temperature to rise above 155°C, thermal shutdown activates turning off the output and reducing the output current to zero. As the junction temperature cools and drops below 140°C, the output turns on and conducts 300 mA into the short, again causing the junction temperature to rise above 155°C. This thermal oscillation between 140°C and 154°C causes a current oscillation between 0 mA and 300 mA that continues as long as the short remains at the output.

Current and thermal limit protections are intended to protect the device against accidental overload conditions. For reliable operation, device power dissipation must be externally limited so junction temperatures do not exceed 125°C.

THERMAL CONSIDERATIONS

In most applications, the ADP320 triple LDO does not dissipate a lot of heat due to high efficiency. However, in applications with a high ambient temperature and high supply voltage to output voltage differential, the heat dissipated in the package is large enough that it can cause the junction temperature of the die to exceed the maximum junction temperature of 125°C.

When the junction temperature exceeds 155°C, the converter enters thermal shutdown. It recovers only after the junction temperature has decreased below 140°C to prevent any permanent damage. Therefore, thermal analysis for the chosen application is very important to guarantee reliable performance over all conditions. The junction temperature of the die is the sum of the ambient temperature of the environment and the temperature rise of the package due to the power dissipation, as shown in Equation 2.

To guarantee reliable operation, the junction temperature of the ADP320 triple LDO must not exceed 125°C. To ensure that the junction temperature stays below this maximum value, the user needs to be aware of the parameters that contribute to junction temperature changes. These parameters include ambient temperature, power dissipation in the power device, and thermal resistances between the junction and ambient air (θ_{JA}). The θ_{JA} number is dependent on the package assembly compounds used and the amount of copper to which the GND pins of the package are soldered on the PCB. Table 6 shows typical θ_{JA} values for the ADP320 triple LDO for various PCB copper sizes.

Table 6. Typical θ_{JA} Values

Copper Size (mm ²)	ADP320 Triple LDO (°C/W)
JEDEC ¹	49.5
100	83.7
500	68.5
1000	64.7

¹ Device soldered to JEDEC standard board.

The junction temperature of the ADP320 triple LDO can be calculated from the following equation:

$$T_J = T_A + (P_D \times \theta_{JA}) \quad (2)$$

where:

T_A is the ambient temperature.

P_D is the power dissipation in the die, given by

$$P_D = \Sigma[(V_{IN} - V_{OUT}) \times I_{LOAD}] + \Sigma(V_{IN} \times I_{GND}) \quad (3)$$

where:

I_{LOAD} is the load current.

I_{GND} is the ground current.

V_{IN} and V_{OUT} are input and output voltages, respectively.

Power dissipation due to ground current is quite small and can be ignored. Therefore, the junction temperature equation simplifies to

$$T_J = T_A + \{\Sigma[(V_{IN} - V_{OUT}) \times I_{LOAD}] \times \theta_{JA}\} \quad (4)$$

As shown in Equation 4, for a given ambient temperature, input-to-output voltage differential, and continuous load current, there exists a minimum copper size requirement for the PCB to ensure the junction temperature does not rise above 125°C. Figure 47 to Figure 50 show junction temperature calculations for different ambient temperatures, total power dissipation, and areas of PCB copper.

In cases where the board temperature is known, the thermal characterization parameter, Ψ_{JB} , may be used to estimate the junction temperature rise. T_J is calculated from T_B and P_D using the formula

$$T_J = T_B + (P_D \times \Psi_{JB}) \quad (5)$$

The typical Ψ_{JB} value for the 16-lead 3 mm × 3 mm LFCSP is 25.2°C/W.

PRINTED CIRCUIT BOARD LAYOUT CONSIDERATIONS

Heat dissipation from the package can be improved by increasing the amount of copper attached to the pins of the ADP320 triple LDO. However, as can be seen from Table 6, a point of diminishing returns eventually is reached, beyond which an increase in the copper size does not yield significant heat dissipation benefits.

Place the input capacitor as close as possible to the VINx and GND pins. Place the output capacitors as close as possible to the VOUTx and GND pins. Use 0402 or 0603 size capacitors and resistors to achieve the smallest possible footprint solution on boards where area is limited.
