

## FEATURES

### Stereo Analog to Digital Converter (ADC)

Supports 48/96 kHz Sample Rates

102 dB Dynamic Range

Single-Ended Input

Automatic Level Control

### Stereo Digital to Analog Converter (DAC)

Supports 32/44.1/48/96/192 kHz Sample Rates

103 dB Dynamic Range

Differential Output

### Asynchronous operation of ADC and DAC

### Stereo Sample Rate Converter (SRC)

Input/Output Range - 8 - 96 kHz

140 dB Dynamic Range

### Digital Interfaces

Record

Playback

Aux Record

Aux Playback

### S/PDIF (IEC60958) Input & Output

Digital Interface Receiver (DIR)

Digital Interface Transmitter (DIT)

### PLL based Audio MCLK Generators

Generates Required DVDR System MCLKs

Device Control via SPI compatible serial port

64-Lead LQFP Package

## APPLICATIONS

DVD-Recordable

All Formats

CD-R/W

## PRODUCT OVERVIEW

The ADAV802 is a stereo audio codec intended for applications, such as DVD or CD recorders, requiring high performance, flexible and cost effective playback and record functionality. The ADAV802 features Analog Devices proprietary, high performance converter cores to provide record (ADC), playback (DAC) and format conversion (SRC) in a single chip. The ADAV802 record channel features variable input gain to allow for adjustment of recorded input levels and Automatic Level Control, followed by a high performance stereo ADC whose digital output is sent to the record interface. The record channel also features Level Detectors which can be used in feedback loops to adjust input levels for optimum recording. The playback channel features a high performance stereo DAC with independent digital volume control.

The Sample Rate Converter (SRC) provides high performance sample-rate conversion to allow inputs and outputs requiring different sample rates to be matched. The SRC input can be selected from Playback, Auxiliary, DIR or ADC (record). The SRC output can be applied to the Playback DAC, both main and Auxiliary record channels and a DIT. (continued on Page 12)

## ABSOLUTE MAXIMUM RATINGS

Table 17.

Parameter	Rating
DVDD to DGND and ODVDD to DGND	0 V to 4.6 V
AVDD to AGND	0 V to 4.6 V
Digital Inputs	DGND – 0.3 V to DVDD + 0.3 V
Analog Inputs	AGND – 0.3 V to AVDD + 0.3 V
AGND to DGND	–0.3 V to +0.3 V
Reference Voltage	Indefinite short circuit to ground
Soldering (10 s)	+300°C

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

### ESD CAUTION

ESD (electrostatic discharge) sensitive device. Electrostatic charges as high as 4000 V readily accumulate on the human body and test equipment and can discharge without detection. Although this product features proprietary ESD protection circuitry, permanent damage may occur on devices subjected to high energy electrostatic discharges. Therefore, proper ESD precautions are recommended to avoid performance degradation or loss of functionality.

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 2. 64-Lead Plastic Quad Flatpack [LQFP] (ST-520)

Table 18. ADAV802 Pin Function Descriptions

Pin Number	Input/Output	Mnemonic	Description
1	INPUT	VINR	Analog Audio Input - Right Channel
2	INPUT	VINL	Analog Audio Input - Left Channel
3		AGND	Analog Ground
4		AVDD	Analog Voltage Supply
5		DIR_LF	DIR Phase Locked Loop (PLL) Loop Filter Pin
6		DIR_GND	Supply Ground for DIR Analog Section. This pin should be connected to AGND
7		DIR_VDD	Supply for DIR Analog Section. This pin should be connected to AVDD
8	INPUT	RESET	Reset input (Active Low)
9	INPUT	CLATCH	Chip Select (Control Latch) Pin of SPI compatible control interface

33		DGND	Digital Ground
34		DVDD	Digital Supply Voltage
35	INPUT	MCLKI	External MCLK Input
36	OUTPUT	MCLKO	Oscillator Output
37	INPUT	XOUT	Crystal Input
38	INPUT	XIN	Crystal or External MCLK Input
39	OUTPUT	SYSCLK3	System Clock 3 (from PLL 2)
40	OUTPUT	SYSCLK2	System Clock 2 (from PLL 2)
41	OUTPUT	SYSCLK1	System Clock 1 (from PLL 1)
42		DGND	Digital Ground
43		PLL_VDD	Supply for PLL Analog Section. This pin should be connected to AVDD
44		PLL_GND	Ground for PLL Analog Section. This pin should be connected to AGND
45		PLL_LF1	Loop Filter for PLL1
46		PLL_LF2	Loop Filter for PLL2
47		ADGND	Analog Ground (Mixed Signal)
48		ADVDD	Analog Voltage Supply (Mixed Signal). This pin should be connected to AVDD
49	OUTPUT	VOUTRP	Right Channel Differential Analog Output (Positive)
50	OUTPUT	VOUTRN	Right Channel Differential Analog Output (Negative)
51	OUTPUT	VOUTLP	Left Channel Differential Analog Output (Positive)
52	OUTPUT	VOUTLN	Left Channel Differential Analog Output (Negative)
53		AVDD	Analog Voltage Supply
54		AGND	Analog Ground
55		FILTD	Output DAC Reference Decoupling
56		AGND	Analog Ground
57		VREF	Voltage Reference Voltage
58		AGND	Analog Ground
59		AVDD	Analog Voltage Supply
60		CAPRN	ADC Modulator Input Filter Capacitor (Right Channel - Negative)
61		CAPRP	ADC Modulator Input Filter Capacitor (Right Channel - Positive)
62		AGND	Analog Ground
63		CAPLP	ADC Modulator Input Filter Capacitor (Left Channel - Positive)
64		CAPLN	ADC Modulator Input Filter Capacitor (Left Channel - Negative)

*(continued from Page 1)*

Operation of the ADAV802 is controlled via an SPI compatible serial interface which allows individual Control Register settings to be programmed. The ADAV802 operates from a single analog +3.3 V power supply - and a digital power supply of +3.3 V with optional digital interface range of 3.0 V to +3.6 V.

It is housed in a 64-lead LQFP package and is characterized for operation over the commercial temperature range  $-40^{\circ}\text{C}$  to  $85^{\circ}\text{C}$ .

## FUNCTIONAL DESCRIPTION

### ADC SECTION

The ADAV802's ADC section is implemented using a 2<sup>nd</sup> order multi-bit (5-bits) Sigma-Delta modulator. The modulator is sampled at either half the ADC MCLK rate (Modulator Clock =  $128 \times f_s$ ) or a quarter of the ADC MCLK rate (Modulator Clock =  $64 \times f_s$ ). The digital decimator consists of a Sinc<sup>5</sup> filter followed by a cascade of 3 half-band FIR filters. The Sinc decimates by a factor of 16 at 48 kHz and by 8 at 96 kHz. Each of the half-band filters decimates by a factor of 2. Figure 3 below shows the detail of the ADC section. The ADC can be clocked by a number of different clock sources to control the sample rate. MCLK selection for the ADC is set by Internal Clocking Control Register 1 (address = 0x76). The ADC provides an output word of up to 24 bits in resolution in 2s complement format. The output word can be routed to the output ports, to the sample rate converter or to the SPDIF digital transmitter.

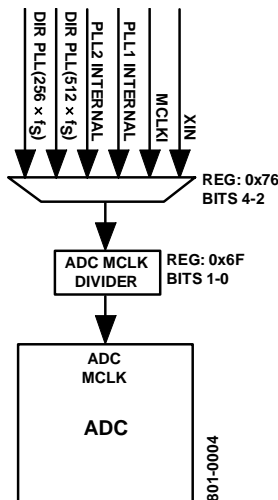

Figure 3. Clock Path Control on the ADC

Figure 5. ADC Block Diagram

### Programmable Gain Amplifier (PGA)

The input of the record channel features a PGA which converts the single-ended signal to a differential signal which is applied to the analog sigma-delta modulator of the ADC. The PGA can be programmed to amplify a signal by up to 24dB in 0.5dB increments. Figure 4 details the structure of the PGA circuit.

Figure 4. PGA Block Diagram

### Analog Sigma Delta Modulator

The ADC features a 2<sup>nd</sup> order, multi-bit, Sigma-Delta modulator. The input features two integrators in cascade followed by a flash converter. This multi-bit output is directed to a scrambler, followed by a DAC for loop feedback. The Flash ADC output is also converted from "thermometer" coding to "binary" coding for input as a 5-bit word to the decimator. Figure 5 shows the ADC block diagram.

The ADC also features independent digital volume control for the left and right channels. The volume control consists of 256 linear steps with each step reducing the digital output codes by 0.39%. Each channel also has a peak detector which records the peak level of the input signal. The peak detector register is cleared by reading it.

### Selecting A Sample Rate

The sample rate of the ADC is always  $256 \times f_s$ . To facilitate different MCLKs the ADC block has a programmable divider which allows the MCLK to be divided by 1, 2 or 3 before being applied to the ADC. This allows for MCLKs of  $256 \times f_s$ ,  $512 \times f_s$  or  $768 \times f_s$  to be applied to the ADC. To synchronize the data output port with the ADC the same divider setting should be applied to the Internal Clock (ICLK1 or ICLK2) which is controlling the output port. The Internal Clock dividers are shown in Figure 34. By default the  $\Sigma\Delta$  modulator runs at ADC MCLK/2. The modulator is designed to run with a maximum clock rate of 6.144MHz. For cases where higher sample rates would run the modulator at speeds higher than this the user can select divide the ADC MCLK by 4 before it is applied to the modulator. To compensate for this the modulator uses an alternate filter configuration. The divide setting is selected by the AMC bit in ADC Control Register 1.

### Automatic Level Control (ALC)

The ADC record channel features a programmable automatic level control block. This block monitors the level of the ADC output signal and will automatically reduce the gain if the signal at the input pins causes the ADC output to exceed a preset limit. This function can be useful to maximize the signal dynamic range when the input level is not well-defined. The PGA can be used to amplify the unknown signal and the ALC will reduce the gain until the ADC output is within the preset limits. This results in maximum front-end gain. Since the ALC block monitors the output of the ADC the volume control function should not be used. The ADC volume control scales the results from the ADC and any distortion caused by the input signal exceeding the input range of the ADC will still be present at the output of the ADC but scaled by a value determined by the volume control register. The ALC block consists of two functions, Attack Mode and Recovery Mode. The Recovery Mode consists of three settings, namely, No Recovery, Normal Recovery and Limited Recovery. Each of these modes is discussed in detail below. Figure 6 shows an overall flow diagram of the ALC block.

#### Attack Mode

When the absolute value of the ADC output exceeds the level set by the Attack Threshold bits in the ALC Control Register 2, Attack Mode is initiated. The PGA gain for both channels is reduced by one step (0.5dB). The ALC will then wait for a time determined by the Attack Timer bits before sampling the ADC output value again. If the ADC output is still above the threshold the PGA gain is reduced by a further step. This procedure continues until the ADC output is below the limit set by the Attack Threshold bits. The initial gains of the PGAs are defined by ADC Left PGA Gain Register and ADC Right PGA Gain Register and may be different values. The ALC simply adds or subtracts a common gain offset to these values. The

ALC will preserve any gain difference in dB as defined by those registers. At no time will the PGA gains exceed their initial values. Therefore, the initial gain setting also serves as a maximum value.

The Limit Detection Mode bit in ALC Control Register 1 determines how the ALC should respond to an ADC output which exceeds the set limits. If this bit is a one then both channels must exceed the threshold before the gain is reduced. This mode can be used to prevent unnecessary gain reduction due to spurious noise on a single channel. If the Limit Detection Mode bit is a zero the gain will be reduced when either channel exceeds the threshold.

#### No Recovery Mode

By default there is no gain recovery. Once the gain has been reduced it will not be recovered until the ALC has been reset, by toggling the ALCEN bit in ALC Control Register 1 or by writing any value to ALC Control Register 3. The latter option is more efficient as it requires only one write operation to reset the ALC function. No Recovery Mode prevents volume modulation of the signal, caused by adjusting the gain, which can create undesirable artifacts in the signal. Since the gain can be reduced but not recovered, care should be taken that spurious signals do not interfere with the input signal as these may trigger a gain reduction unnecessarily.

#### Normal Recovery

This mode allows for the PGA gain to be recovered providing that the input signal meets certain criteria. Firstly, the ALC must not be in Attack Mode, i.e., the PGA gain has been reduced sufficiently such that the input signal is below the level set by the Attack Threshold bits. Secondly, the output result from the ADC must be below the level set by the Recovery Threshold bits in ALC Control Register. If both of these criteria are met the gain is recovered by one step (0.5dB). The gain is incrementally restored to its original value assuming the ADC output level is below the Recovery Threshold at intervals determined by the Recovery Time bits. Should the ADC output level exceed the Recovery Threshold while the PGA gain is being restored the PGA gain value will be held and will not continue restoration until the ADC output level is again below the Recovery Threshold. Once the PGA gain is restored to its original value it will not be changed again unless the ADC output value exceeds the Attack Threshold and the ALC then enters Attack Mode. Care should be exercised when using this mode to choose values for the Attack and Recovery thresholds to prevent excessive volume modulation caused by continuous gain adjustments.

#### Limited Recovery

Limited Recovery Mode offers a compromise between No

Recovery and Normal Recovery Modes. If the output level of the ADC exceeds the Attack Threshold then Attack Mode is initiated. When Attack Mode has reduced the PGA gain to suitable levels the ALC will attempt to recovery the gain to its original level. If the ADC output level exceeds the level set by the Recovery Threshold bits a counter is incremented (GAINCNTR). This counter is incremented, at intervals equal

to the Recovery Time selection, if the ADC has any excursion above the Recovery Threshold. If the counter reaches its maximum value, determined by the GAINCNTR bits in ALC Control Register 1, the PGA gain is deemed suitable and no further gain recovery is attempted. If, at any time, the ADC output level exceeds the Attack Threshold, Attack Mode is reinitiated and the counter is reset

Figure 6. ALC Flow Diagram

### DAC SECTION

The ADAV802 has two DAC channels arranged as a stereo pair with differential analog outputs. Each channel has its own independently programmable attenuator, adjustable in 128 steps of 0.375dB per step. The DAC can receive data from the playback or auxiliary input ports, the SRC, the ADC or the DIR. Each analog output pin sits at a dc level of VREF, and swings 1.0 Vrms for a 0dB digital input signal. A single op-amp third-order external low-pass filter is recommended to remove high-frequency noise present on the output pins. Note that the use of op amps with low slew rate or low bandwidth may cause high frequency noise and tones to fold down into the audio band; care should be exercised in selecting these components. The FILTD and FILTR pins should be bypassed by external capacitors to AGND. The FILTD pin is used to reduce the noise of the internal DAC bias circuitry, thereby reducing the DAC output noise. The voltage at the VREF pin, FILTR can be used to bias external op amps used to filter the output signals. For applications where the FILTR is required to drive external op amps which may draw more than 50µA or may have dynamic load changes extra buffering should be used to preserve the quality of the ADAV802 reference. The digital input data source for the DAC can be selected from a number of available sources, by programming the appropriate bits in the Datapath Control register. Figure 7 shows how the digital data source and MCLK source for the DAC are selected. Each DAC has an independent volume register giving 256 steps of control with each step giving approximately 0.375dB of attenuation. Each DAC also has a peak level register which records the peak value of the digital audio data. Reading the register clears the peak .

### Selecting a Sample Rate

Correct operation of the DAC is dependant upon the data rate provided to the DAC, the master clock applied to the DAC and the selected interpolation rate. By default the DAC assumes that the MCLK rate is 256 times the sample rate which requires an 8 times oversampling rate. This combination is suitable for sample rates up to 48kHz. For the case of a 96kHz data rate which has a 24.576MHz MCLK ( $256 \times f_s$ ) associated with it the DAC MCLK divider should be set to divide the MCLK by 2. This will prevent the DAC engine being run too fast. To compensate for the reduced MCLK rate the interpolator should be selected to operate in  $4 \times$  ( $\text{DAC MCLK} = 128 \times f_s$ ). Similar combinations can be selected for different sample rates.

Figure 7. Clock and data Path Control on the DAC

Figure 8. DAC Block Diagram

## SRC FUNCTIONAL OVERVIEW

### THEORY OF OPERATION

Asynchronous sample rate conversion is converting data from at the same or different sample rate. The simplest approach to an asynchronous sample rate conversion is the use of a zero-order hold between the two samplers shown in Figure 9. In an asynchronous system,  $T_2$  is never equal to  $T_1$  nor is the ratio between  $T_2$  and  $T_1$  rational. As a result, samples at  $f_{S\_OUT}$  will be repeated or dropped producing an error in the re-sampling process. The frequency domain shows the wide side lobes that result from this error when the sampling of  $f_{S\_OUT}$  is convolved with the attenuated images from the  $\sin(x)/x$  nature of the zero-order hold. The images at  $f_{S\_IN}$ , dc signal images, of the zero-order hold are infinitely attenuated. Since the ratio of  $T_2$  to  $T_1$  is an irrational number, the error resulting from the re-sampling at  $f_{S\_OUT}$  can never be eliminated. However, the error can be significantly reduced through interpolation of the input data at  $f_{S\_IN}$ . The sample rate converter in the ADAV802 is conceptually interpolated by a factor of  $2^{20}$ .

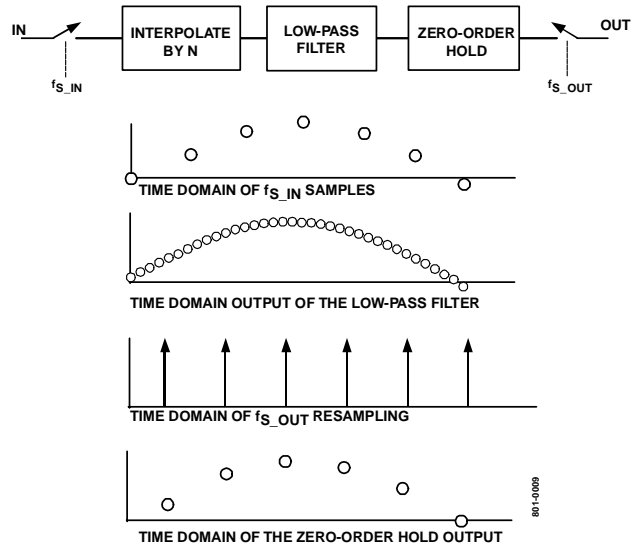

Figure 10. SRC Time Domain

In the frequency domain shown in Figure 11, the interpolation expands the frequency axis of the zero-order hold. The images from the interpolation can be sufficiently attenuated by a good low-pass filter. The images from the zero-order hold are now pushed by a factor of  $2^{20}$  closer to the infinite attenuation point of the zero-order hold, which is  $f_{S\_IN} \times 2^{20}$ . The images at the zero-order hold are the determining factor for the fidelity of the output at  $f_{S\_OUT}$ . The worst-case images can be computed from the zero-order hold frequency response, maximum image =  $\sin(\times F/f_{S\_INTERP})/(\times F/f_{S\_INTERP})$ .  $F$  is the frequency of the worst-case image that would be  $2^{20} \times f_{S\_IN} \pm f_{S\_IN}/2$ , and  $f_{S\_INTERP}$  is  $f_{S\_IN} \times 2^{20}$ .

The following worst-case images would appear for  $f_{S\_IN} = 192$  kHz:

Image at  $f_{S\_INTERP} - 96$  kHz = -125.1 dB

Image at  $f_{S\_INTERP} + 96$  kHz = -125.1 dB

Figure 9. Zero Order Hold Being Used by  $f_{S\_OUT}$  to Resample Data from  $f_{S\_IN}$

### CONCEPTUAL HIGH INTERPOLATION MODEL

Interpolation of the input data by a factor of  $2^{20}$  involves placing  $(2^{20} - 1)$  samples between each  $f_{S\_IN}$  sample. Figure 10 shows both the time domain and the frequency domain of interpolation by a factor of  $2^{20}$ . Conceptually, interpolation by  $2^{20}$  would involve the steps of zero-stuffing  $(2^{20} - 1)$  number of samples between each  $f_{S\_IN}$  sample and convolving this interpolated signal with a digital low-pass filter to suppress the images. In the time domain, it can be seen that  $f_{S\_OUT}$  selects the closest  $f_{S\_IN} \times 2^{20}$  sample from the zero-order hold as opposed to the nearest  $f_{S\_IN}$  sample in the case of no interpolation. This significantly reduces the re-sampling error.

Figure 11. Frequency Domain of the Interpolation and Resampling

**HARDWARE MODEL**

The output rate of the low-pass filter of Figure 10 would be the interpolation rate,  $2^{20} \times 192000 \text{ kHz} = 201.3 \text{ GHz}$ . Sampling at a rate of 201.3 GHz is clearly impractical, not to mention the number of taps required to calculate each interpolated sample. However, since interpolation by  $2^{20}$  involves zero-stuffing  $2^{20}-1$  samples between each  $f_{s\_IN}$  sample, most of the multiplies in the low-pass FIR filter are by zero. A further reduction can be realized by the fact that since only one interpolated sample is taken at the output at the  $f_{s\_OUT}$  rate, only one convolution needs to be performed per  $f_{s\_OUT}$  period instead of  $2^{20}$  convolutions. A 64-tap FIR filter for each  $f_{s\_OUT}$  sample is sufficient to suppress the images caused by the interpolation. The difficulty with the above approach is that the correct interpolated sample needs to be selected upon the arrival of  $f_{s\_OUT}$ . Since there are  $2^{20}$  possible convolutions per  $f_{s\_OUT}$  period, the arrival of the  $f_{s\_OUT}$  clock must be measured with an accuracy of  $1/201.3 \text{ GHz} = 4.96 \text{ ps}$ . Measuring the  $f_{s\_OUT}$  period with a clock of 201.3 GHz frequency is clearly impossible; instead, several coarse measurements of the  $f_{s\_OUT}$  clock period are made and averaged over time.

Another difficulty with the above approach is the number of coefficients required. Since there are  $2^{20}$  possible convolutions with a 64-tap FIR filter, there needs to be  $2^{20}$  polyphase coefficients for each tap, which requires a total of  $2^{26}$  coefficients. To reduce the amount of coefficients in ROM, the SRC stores small subset of coefficients and performs a high order interpolation between the stored coefficients. So far the above approach works for the case of  $f_{s\_OUT} > f_{s\_IN}$ . However, in the case when the output sample rate,  $f_{s\_OUT}$ , is less than the input sample rate,  $f_{s\_IN}$ , the ROM starting address, input data,

and the length of the convolution must be scaled. As the input sample rate rises over the output sample rate, the anti-aliasing filter's cutoff frequency has to be lowered because the Nyquist frequency of the output samples is less than the Nyquist frequency of the input samples. To move the cutoff frequency of the antialiasing filter, the coefficients are dynamically altered and the length of the convolution is increased by a factor of  $(f_{s\_IN}/f_{s\_OUT})$ .

This technique is supported by the Fourier transform property that if  $f(t)$  is  $F(\omega)$ , then  $f(k \times t)$  is  $F(\omega/k)$ . Thus, the range of decimation is simply limited by the size of the RAM.

**THE SAMPLE RATE CONVERTER ARCHITECTURE**

The architecture of the sample rate converter is shown in Figure 12. The sample rate converter's FIFO block adjusts the left and right input samples and stores them for the FIR filter's convolution cycle. The  $f_{s\_IN}$  counter provides the write address to the FIFO block and the ramp input to the digital servo loop. The ROM stores the coefficients for the FIR filter convolution and performs a high order interpolation between the stored coefficients. The sample rate ratio block measures the sample rate for dynamically altering the ROM coefficients and scaling of the FIR filter length as well as the input data. The digital servo loop automatically tracks the  $f_{s\_IN}$  and  $f_{s\_OUT}$  sample rates and provides the RAM and ROM start addresses for the start of the FIR filter convolution.

Figure 12. Architecture of the Sample Rate Converter

The FIFO receives the left and right input data and adjusts the amplitude of the data for both the soft muting of the sample rate converter and the scaling of the input data by the sample rate ratio before storing the samples in the RAM. The input data is scaled by the sample rate ratio because as the FIR filter length of the convolution increases, so does the amplitude of the convolution output. To keep the output of the FIR filter from saturating, the input data is scaled down by multiplying it by  $(f_{s\_OUT}/f_{s\_IN})$  when  $f_{s\_OUT} < f_{s\_IN}$ . The FIFO also scales the input data for muting and unmuting of the SRC.

The RAM in the FIFO is 512 words deep for both left and right channels. An offset to the write address provided by the  $f_{s\_IN}$  counter is added to prevent the RAM read pointer from ever overlapping the write address. The minimum offset on the SRC

is 16 samples. However, the Group Delay and Mute In register can be used to increase this offset. The number of input samples added to the write pointer of the FIFO on the SRC is 16 + Bits 6-0 of the Group Delay register. This feature is useful in variable speed applications in order to prevent the read pointer to the FIFO running ahead of the write pointer. When set, bit 7 of the Group Delay and Mute In register will soft mute the sample rate. Increasing the offset of the write address pointer is useful for applications when small changes in the sample rate ratio between  $f_{S\_IN}$  and  $f_{S\_OUT}$  are expected. The maximum decimation rate can be calculated from the RAM word depth and the group delay as  $(512-16)/64$  taps = 7.75 for short group delay and  $(512-64)/64$  taps = 7 for long group delay.

The digital servo loop is essentially a ramp filter that provides the initial pointer to the address in RAM and ROM for the start of the FIR convolution. The RAM pointer is the integer output of the ramp filter while the ROM is the fractional part. The digital servo loop must be able to provide excellent rejection of jitter on the  $f_{S\_IN}$  and  $f_{S\_OUT}$  clocks as well as measure the arrival of the  $f_{S\_OUT}$  clock within 4.97 ps. The digital servo loop will also divide the fractional part of the ramp output by the ratio of  $f_{S\_IN}/f_{S\_OUT}$  for the case when  $f_{S\_IN} > f_{S\_OUT}$ , to dynamically alter the ROM coefficients.

The digital servo loop is implemented with a multi-rate filter. To settle the digital servo loop filter more quickly upon startup or a change in the sample rate, a "fast mode" was added to the filter. When the digital servo loop starts up or the sample rate is changed, the digital servo loop kicks into "fast mode" to adjust and settle on the new sample rate. Upon sensing the digital servo loop settling down to some reasonable value, the digital servo loop will kick into "normal" or "slow mode."

During "fast mode" the MUTE\_OUT bit in the Sample Rate Error register is asserted to let the user know clicks or pops may be present in the digital audio data. The output of the SRC can be muted, by asserting bit 7 of the Group Delay & Mute register until the SRC has changed to "slow mode". The MUTE\_OUT bit can be set to generate an interrupt when the SRC changes to "slow mode" indicating that the data will be sample rate converted accurately. The frequency response of the digital servo loop for "fast mode" and "slow mode" are shown in Figure 14. The FIR filter is a 64-tap filter in the case of  $f_{S\_OUT} \geq f_{S\_IN}$  and is  $(f_{S\_IN}/f_{S\_OUT}) \times 64$  taps for the case when  $f_{S\_IN} > f_{S\_OUT}$ . The FIR filter performs its convolution by loading in the starting address of the RAM address pointer and the ROM address pointer from the digital servo loop at the start of the  $f_{S\_OUT}$  period. The FIR filter then steps through the RAM by decrementing its address by 1 for each tap, and the ROM pointer increments its address by the  $(f_{S\_OUT}/f_{S\_IN}) \times 2^{20}$  ratio for  $f_{S\_IN} > f_{S\_OUT}$  or  $2^{20}$  for  $f_{S\_OUT} \geq f_{S\_IN}$ . Once the ROM address rolls over, the convolution is completed. The convolution is performed for both the left and right channels, and the multiply accumulate circuit used for the convolution is shared between the channels. The  $f_{S\_IN}/f_{S\_OUT}$

sample rate ratio circuit is used to dynamically alter the coefficients in the ROM for the case when  $f_{S\_IN} > f_{S\_OUT}$ . The ratio is calculated by comparing the output of an  $f_{S\_OUT}$  counter to the output of an  $f_{S\_IN}$  counter. If  $f_{S\_OUT} > f_{S\_IN}$ , the ratio is held at one. If  $f_{S\_IN} > f_{S\_OUT}$ , the sample rate ratio is updated if it is different by more than two  $f_{S\_OUT}$  periods from the previous  $f_{S\_OUT}$  to  $f_{S\_IN}$  comparison. This is done to provide some hysteresis to prevent the filter length from oscillating and causing distortion.

**PLL SECTION**

The ADAV802 features a dual PLL configuration to generate independent system clocks for asynchronous operation. Figure 17 shows the block diagram of the PLL section. The PLL generates the internal and system clocks from a 27MHz clock. This clock is generated either by a crystal connected between XIN and XOUT, as shown in Figure 15 or from an external

clock source connected directly to XIN. A 54MHz clock can also be used if the internal clock divider is used. Both PLLs (PLL1 and PLL2) can be programmed independently and cater for a range of sampling rates (32/44.1/48 kHz) with selectable system clock oversampling rates of 256 and 384. Higher oversampling rates can also be selected by enabling the doubling of the sampling rate to give 512 or 768 × f<sub>s</sub> ratios. Note that this option also allows oversampling ratios of 256 or 384 at double sample rates of 64/88.2/96 kHz. The PLL outputs can be routed internally to act as clock sources for the other component blocks such as the ADC, DAC etc. The outputs of the PLLs are also available on the three SYSCLK pins. Figure 18 shows how the PLLs can be configured to provide the sampling clocks.

Figure 15. Crystal Connection

Table 19. PLL Frequency Selection Options

PLL	Sample Rate (f <sub>s</sub> )	MCLK Selection Normal f <sub>s</sub>	Double f <sub>s</sub>
1	32/44.1/48 kHz	256/384×f <sub>s</sub>	512/768×f <sub>s</sub>
2A	64/88.2/96 kHz 32/44.1/48 kHz 64/88.2/96 kHz	256/384×f <sub>s</sub>	256/384×f <sub>s</sub> 512/768×f <sub>s</sub> 256/384×f <sub>s</sub>
2B	Same as f <sub>s</sub> selected for PLL 2A	512×f <sub>s</sub> 512×f <sub>s</sub>	

The PLLs require a some external components to operate correctly. These components, shown in Figure 16 form a loop filter which integrates the current pulses from a charge pump and produces a voltage which is used to tune the VCO. Good quality capacitors, such as PPS film, are recommended .Figure 17 shows a block diagram of the PLL section including master clock selection. Figure 18 shows how the clock frequencies at the clock output pins, SYSCLK1-3 and the internal PLL clock values, PLL1 and PLL2, are selected. The clock nodes, PLL1 and PLL2, can be used as master clocks for the other blocks in the ADAV802 such as the DAC or ADC. The PLL has separate supply and ground pins and these should be as clean as possible to prevent electrical noise being converted into clock jitter by coupling onto the loop filter pins.

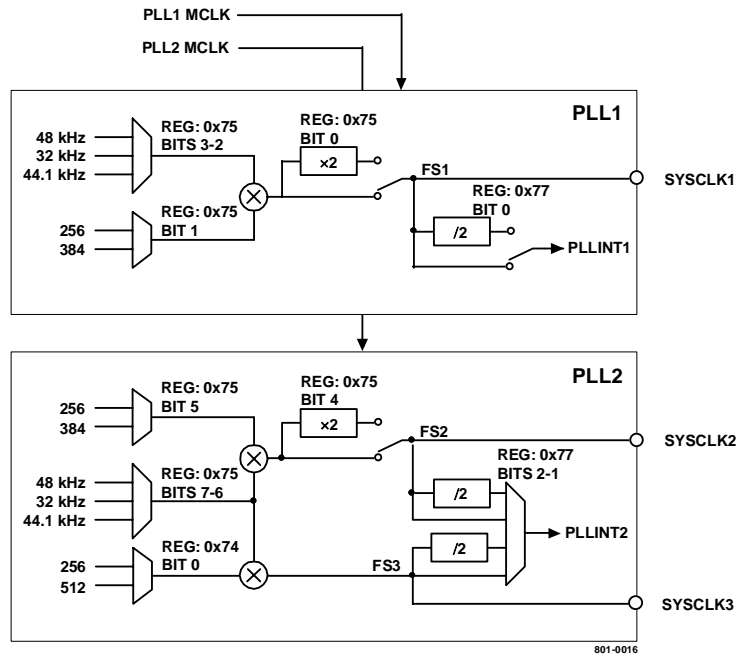

Figure 18. PLL Clocking Scheme

**SPDIF TRANSMITTER AND RECEIVER**

The ADAV802 contains an integrated SPDIF transmitter and receiver. The transmitter consists of a single output pin, DITOUT, on which the biphase encoded data appears. The SPDIF transmitter source can be selected from the different blocks making up the ADAV802. Additionally the clock source for the SPDIF transmitter can be selected from the various clock sources available in the ADAV802. The receiver uses two pins, DIRIN and DIR\_LF. DIRIN accepts the SPDIF input data stream. The DIRIN pin can be configured to accept a digital input level as defined by Table 13 or an input signal with a peak to peak level of 200mV minimum as defined by the IEC60958-3 specification. DIR\_LF is a loop filter pin required by the internal PLL which is used to recover the clock from the SPDIF data stream. The components shown in Figure 22 form a loop filter which integrates the current pulses from a charge pump and produces a voltage which is used to tune the VCO of the clock recovery PLL. The recovered audio data and audio clock can be routed to the different blocks of the ADAV801 as required. Figure 19 shows a conceptual diagram of the DIRIN block.

**Serial Digital Audio Transmission Standards**

The ADAV802 can receive and transmit SPDIF, AES/EBU and IEC-958 serial streams. SPDIF is a consumer audio standard and AES/EBU is a professional audio standard. IEC-958 has both consumer and professional definitions. This data sheet is not intended to fully define or to provide a tutorial for these standards, please contact the international standards setting bodies for the full specifications.

All of these digital audio serial communication schemes encode audio data and audio control information using the biphasemark method. This encoding method minimizes the dc content of the transmitted signal. As can be seen from Figure 23 ones in the original data end up with midcell transitions in the biphasemark encoded data, while zeros in the original data do not. Note that the biphasemark encoded data always has a transition between bit boundaries.

Figure 23. Biphasemark Encoding

Digital audio communication schemes use “preambles” to distinguish between channels (called “subframes”) and between longer term control information blocks (called “frames”). Preambles are particular biphasemark patterns, which contains encoding violations that allow the receiver to uniquely recognize them. These patterns, and their relationship to frames and subframes, are shown in Figure 24 and Figure 25.

	BIPHASE PATTERNS	CHANNEL
X	11100010 OR 00011101	LEFT
Y	11100100 OR 00011011	RIGHT
Z	11101000 OR 00010111	LEFT AND C.S. BLOCKSTART

Figure 24. Biphasemark Encoded Preambles

Figure 25. Preambles, Frames and Subframes

The biphasemark encoding violations are shown in Figure 26. Note that all three preambles include encoding violations. Ordinarily, the biphasemark encoding method results in a polarity transition between bit boundaries.

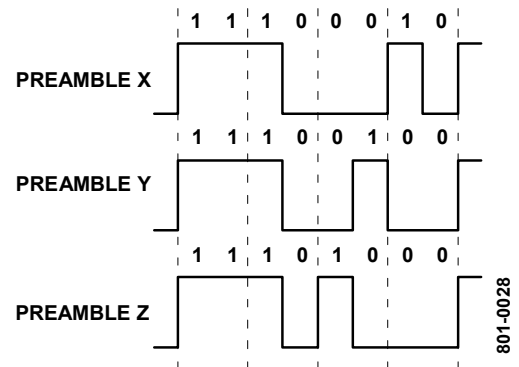

Figure 26. Preambles

The serial digital audio communication scheme are organized using a frame and subframe construction. There are two subframes per frame (ordinarily the left and right channel). Each subframe includes the appropriate four bit preamble, up to 24 bits of audio data, a “validity” (V) bit, a “user” (U) bit, a “channel status” (C) bit and an even “parity” (P) bit. The channel status bits and the user bits accumulate over many frames to convey control information. The channel status bits accumulate over a 192 frame period (called a channel status block). The user bits accumulate over 1176 frames when the interconnect is implementing the so-called “subcode” scheme (EIAJ CP-2401). The organization of the channel status block, frames and subframes are shown in Figure 27 and Figure 28.

Figure 28. Professional

The standards allow for the channel status bits in each subframe to be independent, but ordinarily the channel status bit in the two subframes of each frame are the same. The channel status bits are defined differently for the consumer audio standards and the professional audio standards. The 192 channel status bits are organized into 24 bytes and have the interpretations shown in Figure 27 and Figure 28.

The SPDIF transmitter and receiver have a comprehensive register set. The registers give the user full access to the functions of the SPDIF block such as detecting non-audio and validity bits, Q subcodes, preambles etc. The channel status bits as defined by the IEC60958 and AES3 specification are stored in register buffers for ease of use. An autobuffering function allows for channel status and user bits read by the receiver to be copied directly to the transmitter block removing the need for user intervention.

**Receiver Section**

The ADAV802 uses a double buffering scheme to handle reading Channel Status and User bit information. The Channel Status bits are available as a memory buffer taking up 24 consecutive register locations. The User bits are read using an indirect memory addressing scheme where the Receiver User Bit Indirect Address register is programmed with an offset to the User bit buffer and the Receiver User Bit Data register can be read to determine the User bits at that location. Reading the Receiver User Bit Data register automatically updates the Indirect Address Register to the next location in the buffer. Typically the Receiver User Bit Indirect Address register is programmed to zero, the start of the buffer, and the Receiver User Bit Data register is read repeatedly until all the buffers data has been read. Figure 29 and Figure 30 shows how receiving the Channel Status and User bits is implemented.

Figure 29. Channel Status Buffer

Figure 30. Receiver User Bit Buffer

The SPDIF receive buffer is updated continuously by the incoming SPDIF stream and once all of the channel status bits for the block, 192 for channel A and 192 for channel B, are received the bits are copied into the receiver channel status buffer. This buffer stores all 384 bits of channel status information and the RxCSSWITCH bit in the Channel Status Switch Buffer register determines whether the channel A or channel B status bits are required to be read. The receive channel status bit buffer is 24 bytes long and spans the address range from 0x20 to 0x37.

Since the Channel Status bits of an SPDIF stream rarely change a software interrupt/flag bit, RxCSBINT is provided to notify the host control that either a new block of channel status bits is available or that the first 5 bytes of channel status information

have changed from a previous block. The function of the RxCSBINT is controlled by the RxBCONF3 bit in the Receiver Buffer Configuration Register.

The size of the User bit buffer can be set using by programming the RxBCONF0 bit in the Receiver Buffer Configuration register as shown in Table 20.

**Table 20. RxBCONF3 Functionality**

RxBCONF0	Receiver User Bit Buffer Size
0	384 bits with Preamble Z as the start of the block
1	768 bits with Preamble Z as the start of the block

The updating of the User bit buffer is controlled by bits RxBCONF2-1 and bits 7 to 4 of the Channel Status as shown in Table 21 and Table 22.

**Table 21. RxBCONF2-1 Functionality**

RxBCONF		Receiver User Bit Buffer Configuration
Bit 2	Bit 1	
0	0	User bits are ignored
0	1	Update second buffer when first buffer is full
1	0	Format according to byte 1, bits 4-7 if PRO bit is set. Format according to IEC60958-3 if PRO bit is clear

**Table 22. Automatic User Bit Configuration**

Bits				Automatic Receiver User Bit Buffer Configuration
7	6	5	4	
0	0	0	0	User Bits are ignored
0	1	0	0	AES-18 format, the User bit buffer is treated in the same way as when RxBCONF2-1 = 0b01
1	0	0	0	User bit buffer is updated in the same way as when RxBCONF2-1 = 0b01 and RxBCONF0 = 0b00
1	1	0	0	User defined format, the User bit buffer is treated in the same way as when RxBCONF2-1 = 0b01

When the User bit buffer has been filled, the RxUBINT interrupt bit in the Interrupt Status register will be set, provided that the RxUBINT Mask bit is set, to indicate that the buffer has new information and can be read.

For the special case when the user data is formatted according to the IEC60958-3 standard into messages made of of information units, called IUs, the zeros stuffed between each IU and each message are removed and only the IUs are stored. Once the end of the message is sensed, by more that 8 zeros between IUs, the User bit buffer is updated with the complete message and the first buffer begins looking for the start of the next message. Each IU is stored as a byte consisting of 1, Q, R, S, T, U, V and W bits (see the IEC60958-3 specification for more information). For the case where 96IUs are received, the Q subcode of the IUs is stored in the Q subcode buffer consisting of 10 bytes. The Q subcode is the Q bits taken from each of the

96 IUs. The first 10 bytes, 80 bits, of the Q subcode contain information sent by CD, MD and DAT systems. The last 16 bits of the Q subcode are used to perform a CRC check of the Q subcode. If an error occurs in the CRC check of the Q subcode, the QRCERROR bit will be set. This is a sticky bit and will remain high until the register is read.

**Transmitter Operation**

The SPDIF transmitter has a similar buffer structure to the receive section. The transmitter Channel Status buffer occupies 24 bytes of the register map. This buffer is long enough to store the 192 bits required for one channel of Channel Status information. Setting the TxCSSWITCH bit determines if the data loaded to the Transmitter Channel Status buffer is intended for channel A or channel B. In most cases the channel status bits for channel A and channel B are the same in which case setting the Tx\_A/B\_Same bit will read the data from the Transmitter Channel Status buffer and transmit it on both channels. Since the Channel Status information is rarely changed during transmission the information contained in the buffer is transmitted repeatedly. The Disable\_Tx\_Copy bit can be used to prevent the Channel Status bits from being copied from the Transmitter CS Buffer into the SPDIF Transmitter buffer until the user has finished loading the buffers. This feature is typically used if the channel A and channel B data is different. Setting the bit will prevent the data being copied and clearing the bit will allow the data to be copied and then transmitted. Figure 31 shows how the buffers are organized.

Figure 31. Transmitter Channel Status Buffer

As with the receiver section the transmitted User bits are also double buffered. This is required since, unlike the Channel Status bits, the User bits do not necessarily repeat themselves. The User bits can be buffered in various configuration as Table 23. Transmission of the user bits is determined by the state of the BCONF3 bit. If the bit is 0 the user bits will begin transmitting straight away without alignment to the Z preamble. If this bit is 1 the User bits will not start transmitting until a Z preamble occurs when the TxBCONF2-1 bits are 01.

**Table 23. Transmitter User Bit Buffer Configurations**

TxBCONF2-1		Transmitter User Bit Buffer Configuration
Bit2	Bit1	
0	0	Zeros are transmitted for the User bits
0	1	Host writes User bits to the buffer until it is full
1	0	Write the user bits to the buffer in IUs specified by IEC60958-3 and transmit them according to the standard
1	1	The first 10 bytes of the user bit buffer is configured to store a Q subcode

**Table 24. Transmitter User Bit Buffer Size**

TxBCONF0	Buffer Size
0	384 bits with Preamble Z as the start of the block
1	768 bits with Preamble Z as the start of the block

The transmit buffers can notify the host or micro-controller when the first user bit buffer has been updated and when the second transmit user bit buffer is full using sticky bits and interrupts. The sticky bit TxUBINT, is set when the transmit user buffer has been updated and the second transmit user bit buffer is ready to accept new user bits. The sticky bit, TxFBINT, is set whenever the second transmit user bit buffer is full and any new writes to this buffer will be ignored until the first transmit buffer is updated. These two bits are located in the Interrupt Status register. When the host reads the Interrupt Status register these bits will be cleared. Interrupts for the TxUBINT and TxFBINT sticky bits can be enabled by setting the TxUBMASK and TxFBMASK bits respectively in the Interrupt Status Mask register.

Figure 32. Transmitter User Bit Buffer

**Autobuffering**

The ADAV802 SPDIF receiver and transmitter sections have an autobuffering mode allowing the Channel Status and User bits to be copied automatically from the receiver to the transmitter without user intervention. The Channel Status and User bits can be independently selected for autobuffering using the Auto\_CSBits and Auto\_UBits bits in Autobuffer register

respectively. When the receiver and transmitter are running at the same sample rate the transmitted Channel Status and User bits will be the same as the received Channel Status and User bits. However in many systems it is likely that the receiver and transmitter will not be running at the same frequency. When the transmitter sample rate is higher than receiver sample rate, the Channel Status and User bit block may be repeated sometimes. When the transmitter sample rate is lower than the receiver sample rate, the Channel Status and User bit blocks may be dropped. Since the first 5 bytes of the Channel Status are, typically, constant the can be repeated or dropped and no information is lost. However, if the PRO bit in the channel status is set and the local sample address code and time of day code bytes contain information, these bytes may be repeated or dropped in which case information can be lost. It is up to the user to determine how to handle this case. In the case of the user bits being transmitted according to the IEC60958-3 format the messages contained in the user bits can still be sent without dropping or repeating messages. Since zero-stuffing is allowed between IUs and messages, zeros can be added or subtracted to preserve the messages. For the case when the transmitter sample rate is greater than the receiver sample rate extra zeros are stuffed between the messages. When the sample rate of the transmitter is less than the sample rate of the receiver, the zeros stuffed between the messages will be subtracted. If there is not enough zeros between the messages to be subtracted, the zeros between IUs will be subtracted as well. The Zero\_Stuff\_IU bit in the Autobuffer register enables zeros to be added or subtracted between messages.

**Interrupts**

The ADAV802 provides interrupt bits to indicate the presence of certain conditions which may require attention. Reading the Interrupt Status register will allow the user to determine if any of the interrupts have been asserted. The bits of the Interrupt Status register will remain high, if set, until the register is read. Two bits, SRCError and RxError indicate interrupt conditions in the sample rate converter and an SPDIF receiver error respectively. Both of these condition require a read of the appropriate error register to determine the exact cause of the interrupt. Each interrupt in the Interrupt Status register has an associated mask bit in the Interrupt Status Mask register. The interrupt mask bit must be set for the corresponding interrupt to be generated. This feature allows the user to determine which functions should be responded to. The dual function pin ZEROL/INT can be set to indicate the presence of no audio data on the left channel or the presence of an interrupt being set in the Interrupt Status register. The function of this pin is selected by the INTRPT bit in DAC Control Register 4 as shown in Table 25.

Table 25. ZEROL/INT Pin Functionality

INTRPT	Pin Functionality
0	The pin functions as a ZEROL flag pin
1	The pin functions as an interrupt pin

**SERIAL DATA PORTS**

The ADAV802 contains four flexible serial ports (SPORTs) to allow data transfer to and from the codec. All four SPORTs are independent and can be configured as master or slave ports. In Slave Mode the xLRCLK and xBCLK signals are inputs to the serial ports. In Master Mode, the serial port generates the xLRCLK and xBCLK signals. The master clock for the SPORT can be selected from a number of sources, as shown in Figure 34 and care should be taken to ensure that the clock rate is appropriate for whatever block is connected to the serial port. For example if the ADC is running from the MCLKI input at  $256 \times f_s$  then the master clock for the SPORT should also run from the MCLKI input to ensure that the ADC and serial port are synchronised. The SPORTs can be set to transmit or receive data in I<sup>2</sup>S, Left Justified or Right Justified formats with different word lengths by programming the appropriate bits in the Playback, Auxiliary Input Port, Record and Auxiliary Output Port Control Registers. Figure 33 shows a timing diagram of the serial data port formats.

**CLOCKING SCHEME**

The ADAV802 provides a flexible choice of on-chip and off-chip clocking sources. The on-chip oscillator with dual-PLLs is intended to offer complete system clocking requirements for use with available MPEG encoders, decoders or combination codecs. The oscillator function is designed for generation of a 27 MHz video clock from a 27 MHz crystal connected between XIN and XOUT pins. Capacitors are also required to be connected between these pins and DGND as shown in Figure 15. The capacitor values should be specified by the crystal manufacturer. A square-wave version of the crystal clock is output on the MCLKO pin. If the system has 27MHz clock available this can be connected directly to the XIN pin.

**DATA PATH**

The ADAV802 features a Digital Input/Output switching/multiplexing matrix which gives flexibility to the range of possible Input and Output connections. Digital Input ports include Playback and Auxiliary Input - both 3-wire digital - and S/PDIF (single wire to the on-chip receiver). Output ports include the Record and Auxiliary Output ports - both 3-wire digital - and the S/PDIF port (single wire from the on-chip transmitter). Internally the DIR and DIT are interfaced via 3-wire interfaces. The data path for each input and output port is selected by programming Datapath Control Registers 1 and 2. Figure 35 shows the internal data path structure of the ADAV802.

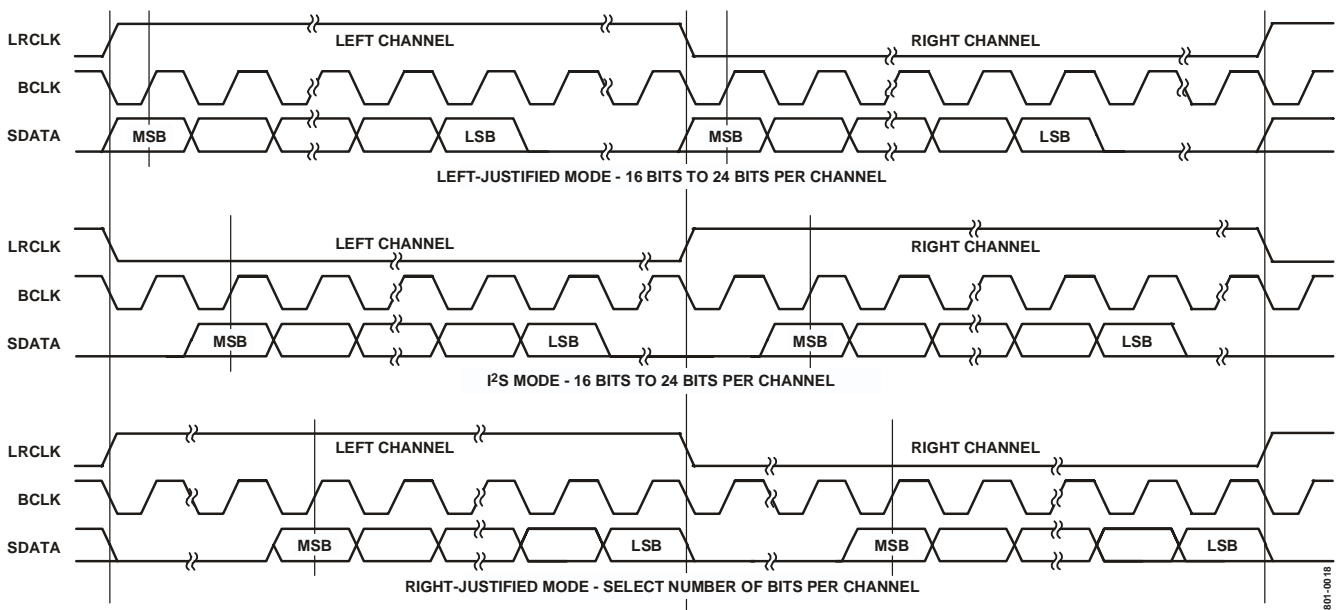

Figure 33. Serial Data Modes

Figure 34. Sport Clocking Scheme

Figure 35. Data Path

**INTERFACE CONTROL**

The ADAV802 has a dedicated control port to allow the internal registers of the ADAV802 to be accessed. Each of the internal registers is 8 bits wide. Where bits are described as reserved (RES) these bits should be programmed as zero.

**SPI Interface**

Control of the ADAV802 is via an SPI compatible serial port. The SPI control port is a 4 wire serial control port with one cycle of data transfer consisting of 16 bits. Figure 36 shows the format of an SPI write/read of the ADAV802. The transfer of data is initiated on the falling edge of CLATCH. The data presented on the first 7 CCLKs represents the register address required to be written to or read from. The 8th bit of data is a

Read/Write bit. If this bit is low the following 8 bits of data will be loaded to register address provided. If this bit is high a read operation is indicated. The contents of the register address will be clocked out on the COUT pin on the following 8 CCLKs. For a read operation the data bits after the Read/Write bits are ignored.

Figure 37. SPI Serial Port Timing Diagram

Figure 38. SPI Control Word Format

**Block Reads and Writes**

The ADAV802 provides the user with the ability to write to or read from a block of registers in one continuous operation. In SPI mode, the CLATCH line should be held low for longer than the 16 CCLK periods to use the block read/write mode. For a write operation, once the LSB has been clocked into the ADAV802, on the 16th CCLK the register address as specified by the first 7 bits of the write operation is incremented and the next 8 bits will be clocked into the next Register Address. The read operation is similar. Once the LSB of a read register operation has been clocked out the Register Address is incremented and the data from the next register will be clocked out on the following 8 CCLKs. Figure 39 and Figure 40 show the timing diagrams for the block write and read operations.

	<b>RxValidity</b>	<b>Emphasis</b>	<b>Non-Audio</b>	<b>NonAudio Preamble</b>	<b>CRC-Error</b>	<b>No-Stream</b>	<b>BiPhase/Parity</b>	<b>Lock</b>
	7	6	5	4	3	2	1	0
<b>ADDRESS = 0011000</b>								
<b>RxValidity</b>	This is the VALIDITY bit in the AES3 Received stream							
<b>Emphasis</b>	This bit will be set if the audio data is preemphasized. Once it has been read it will remain high and not generate an interrupt unless it changes state							
<b>NonAudio</b>	This bit will be set when Channel Status Bit 1 (Nonaudio) is set. Once it has been read it will not generate another interrupt unless the data becomes audio or the type of nonaudio data changes							
<b>NonAudio Preamble</b>	This bit will be set if the audio data is nonaudio due to the detection of a Preamble. The NonAudio Preamble Type register will indicate what type of preamble was detected. Once read it will remain in its state and not generate an interrupt unless it has changed state							
<b>CRCError</b>	This bit is the error flag for the channel status CRC error check. This bit will not clear until the Receiver Error Register is read							
<b>NoStream</b>	This bit will be set if there is no AES3/SPDIF stream present at the AES3/SPDIF receiver. Once read it will remain high and not generate an interrupt unless its changes state.							
<b>BiPhase/Parity</b>	This bit will be set if a biphasic or parity error occurred in the AES3/SPDIF stream. This bit will not be cleared until the register is read.							
<b>Lock</b>	This bit will be set if the PLL has locked or cleared when the PLL loses lock. Once read it will remain in its state and not generate an interrupt unless it has changed state.							

Table 49. Receiver Error Mask Register

<b>ADDRESS = 0011010</b>								
<b>TOO_SLOW</b>	This bit is set when the clock to the SRC is too slow, i.e. there are not enough clock cycles to complete the internal convolution.							
<b>OVRL</b>	This bit will be set when the Left Output Data of the sample rate converter has gone over the full-scale range and has been clipped. This bit will not be cleared until the register is read.							
<b>OVRR</b>	This bit will be set when the Right Output Data of the sample rate converter has gone over the full-scale range and has been clipped. This bit will not be cleared until the register is read.							
<b>MUTE_IND</b>	Mute Indicated. This bit is set when the SRC is in Fast Mode and clicks or pops may be heard in the SRC output data. The output of the SRC can be muted, if required, until the SRC is in Slow Mode. Once read this bit will remain in its state and not generate an interrupt until it has changed state.							

Table 51. Sample Rate Converter Error Mask Register

	RES	RES	RES	RES	RES	OVRL Mask	OVRR Mask	MUTE_IND MASK
	7	6	5	4	3	2	1	0
<b>ADDRESS = 0011011</b>								
<b>OVRL Mask</b>	Masks the OVRL from generating an interrupt 0 = The OVRL bit will not generate an interrupt 1 = The OVRL bit will generate an interrupt							
<b>OVRR Mask</b>	Masks the OVRR from generating an interrupt 0 = The OVRR bit will not generate an interrupt 1 = The OVRR bit will generate an interrupt Reserved							
<b>MUTE_IND MASK</b>	Masks the MUTE_IND from generating an interrupt 0 = The MUTE_IND bit will not generate an interrupt 1 = The MUTE_IND bit will generate an interrupt							

Table 52. Interrupt Status Register

	SRC Error	TxCST-INT	TxUB-INT	TxCs-INT	RxCs-DIFF	RxUB-INT	RxCs-BINT	Rx-ERROR
	7	6	5	4	3	2	1	0
<b>ADDRESS = 0011100</b>								
<b>SRCERROR</b>	This bit will be set if one of the sample rate converter interrupts is asserted, and the host should immediately read the Sample Rate Converter Error register. This bit will remain high until the Interrupt Status register is read							
<b>TxCSTINT</b>	This bit will be set if a write to the transmitter channel status buffer was made while transmitter channel status bits were being copied from transmitter CS buffer to SPDIF Transmit buffer							
<b>TxUBINT</b>	This bit will be set if the SPDIF Transmit buffer is empty. This bit will remain high until the Interrupt Status register is read.							
<b>TxCsINT</b>	This bit will be set if the transmitter channel status bit buffer has transmitted its block of channel status. This bit will remain high until the Interrupt Status register is read							
<b>RxCSDIFF</b>	This bit will be set if the receiver Channel Status A block is different from the receiver Channel Status B clock. This bit will remain high until read but does not generate an interrupt							
<b>RxUBINT</b>	This bit will be set if the Receiver User bit buffer has a new block or message. This bit will remain high until the Interrupt Status register is read.							
<b>RxCsBINT</b>	This bit will be set if a new block of channel status is read when RxBCONF3 = 0 or if the channel status has changed when RxBCONF3 = 1. This bit will remain high until the Interrupt Status register is read.							
<b>RxERROR</b>	This bit will be set if one of the AES3/SPDIF receiver interrupts is asserted and the host should immediately read the Receiver Error register. This bit will remain high until the Interrupt Status register is read.							

Table 53. Interrupt Status Mask Register

	SRSError Mask	TxCSTINT Mask	TxUBINT Mask	TxCSTBINT Mask	RES	RxUBINT Mask	RxCSTBINT Mask	RxError Mask
	7	6	5	4	3	2	1	0
<b>ADDRESS = 0011101</b>		<b>DEFAULT VALUE = 0x00</b>						
<b>SRSError Mask</b>	Masks the SRSError bit from generating an interrupt 0 = The SRSError bit will not generate an interrupt 1 = The SRSError bit will generate and interrupt							
<b>TxCSTINT Mask</b>	Masks the TxCSTBINT bit from generating an interrupt 0 = The TxCSTINT bit will not generate an interrupt 1 = The TxCSTINT bit will generate and interrupt							
<b>TxUBINT Mask</b>	Masks the TxUBINT bit from generating an interrupt 0 = The TxUBINT bit will not generate an interrupt 1 = The TxUBINT bit will generate and interrupt							
<b>RxUBINT Mask</b>	Masks the RxUBINT bit from generating an interrupt 0 = The RxUBINT bit will not generate an interrupt 1 = The RxUBINT bit will generate and interrupt							
<b>RxCSTBINT Mask</b>	Masks the RxCSTBINT bit from generating an interrupt 0 = The RxCSTBINT bit will not generate an interrupt 1 = The RxCSTBINT bit will generate an interrupt							
<b>RxError Mask</b>	Masks the RxError bit from generating an interrupt 0 = The RxError bit will not generate an interrupt 1 = The RxError bit will generate an interrupt

	7	6	5	4	3	2,1	0
<b>ADDRESS = 0011110</b>		<b>DEFAULT VALUE = 0x00</b>					
<b>TxMUTE</b>	Mutes the AES3/SPDIF Transmitter 0 = The Transmitter is not muted 1 = The Transmitter is muted						
<b>SRC_DEEM1-0</b>	Selects the Deemphasis Filter for the input data to the Sample Rate Converter 00 = No Deemphasis 01 = 32 kHz Deemphasis 10 = 44.1 kHz Deemphasis 11 = 48 kHz Deemphasis						

Table 55. NonAudio Preamble Type Register (Read Only)

	RES	RES	RES	DTS-CD RES	Non Audio Preamble	Non Audio Frame	Non Audio Subframe_A	Non Audio Subframe_B
	7	6	5	4	3	2	1	0
<b>ADDRESS = 0011111</b>	<b>DEFAULT VALUE = 0x</b>							
<b>DTS-CD Preamble</b>	Will be set if the DTS-CD Preamble is detect							
<b>NonAudio Frame</b>	This bit will be set if the data received through the AES3/SPDIF Receiver is nonaudio data according to the IEC61937 standard or nonaudio data according to SMPTE337M							
<b>NonAudio Subframe_A</b>	This bit will be set if the data received through Channel A of the AES3/SPDIF Receiver is subframe nonaudio data according to SMPTE337M							
<b>NonAudio Subframe_B</b>	This bit will be set if the data received through Channel B of the AES3/SPDIF Receiver is subframe nonaudio data according to SMPTE337M							

Table 56. Receiver Channel Status Buffer

	RCSB7	RCSB6	RCSB5	RCSB4	RCSB3	RCSB2	RCSB1	RCSB0
	7	6	5	4	3	2	1	0

**ADDRESS = 0100000 to 0110111**

This is the 24 byte Receiver Channel Status Buffer. The PRO bit is stored at address location 0x20, bit 0. This buffer is read only if the channel status is not autobuffered between the receiver and transmitter.

Table 57. Transmitter Channel Status Buffer

	TCSB7	TCSB6	TCSB5	TCSB4	TCSB3	TCSB2	TCSB1	TCSB0
	7	6	5	4	3	2	1	0

**ADDRESS = 0111000 to 1001111**

This is the 24 byte Transmitter Channel Status Buffer. The PRO bit is stored at address location 0x38, bit 0. This buffer is disabled when autobuffering between the receiver and transmitter is enabled.

Table 58. Receiver User Bit Buffer Indirect Address Register

	RxUBADDR07-RxUBADDR00
	7,6,5,4,3,2,1,0

**ADDRESS = 1010000**

**RxUBADDR07-00** Indirect Address pointing to the address location in the Receiver User Bit buffer

Table 59. Receiver User Bit Buffer Data Register

	RxUBDATA07-RxUBDATA00
	7,6,5,4,3,2,1,0

**ADDRESS = 1010001**

**RxUBDATA07-00** A read from this register will read 8 bits of user data from the Receiver User bit buffer pointed to by RxUBADDR7-0. This buffer can be written to when autobuffering of the user bits is enabled otherwise it is a read only buffer

Table 60. Transmitter User Bit Buffer Indirect Address Register

	TxUBADDR07-TxUBADDR00
	7,6,5,4,3,2,1,0

**ADDRESS = 1010010**

**TxUBADDR07-00** Indirect Address pointing to the address location in the Transmitter User Bit buffer

Table 61. Transmitter User Bit Buffer Data Register

TxUBDATA07-TxUBDATA00	
7,6,5,4,3,2,1,0	
<b>ADDRESS = 1010011</b>	
<b>TxUBDATA07-00</b>	A write to this register will write 8 bits of user data to the Transmit User bit buffer pointed to by TxUBADDR7-0. When User Bit autobuffering is enabled this buffer is disabled.

Table 62. Q Subcode CRC Error Status Register (Read Only)

RES	RES	RES	RES	RES	RES	QCRCERROR	QSUB
7	6	5	4	3	2	1	0
<b>ADDRESS = 1010100</b>							
<b>QCRCERROR</b>	This bit will be set if the CRC check of the Q Subcode fails. This bit will remain high but will not generate an interrupt. This bit will be cleared once the register is read.						
<b>QSUB</b>	This bit will be set if a Q subcode has been read into the Q subcode buffer

<b>FSSEL1-0</b>	These bits should equal the sample rate of the ADC 00 = 96 kHz 01 = 48 kHz 10 = 32 kHz 11 = Reserved				
<b>GAINCNR1-0</b>	These bits determine the limit of the counter used in Limited Recovery Mode 00 = 3 01 = 7 10 = 15 11 = 31				
<b>RECMODE1-0</b>	These bits determine which recovery mode is used by the ALC section 00 = No Recovery 01 = Normal Recovery 10 = Limited Recovery 11 = Reserved				
<b>LIMDET</b>	Limit Detect Mode 0 = ALC is used when either channel exceeds the set limit 1 = ALC is used only when both channels exceed the set limit				
<b>ALCEN</b>	ALC Enable 0 = Disable ALC 1 = Enable ALC				

Table 89. ALC Control Register 2

	<b>RES</b>	<b>RECTH1-0</b>	<b>ATKTH1-0</b>	<b>RECTIME1-0</b>	<b>ATKTIME</b>
	7	6,5	4,3	2,1	0
<b>ADDRESS = 1111100</b>	<b>Default = 0x52</b>				
<b>RECTH1-0</b>	Recovery Threshold 00 = -2 dB 01 = -3 dB 10 = -4 dB 11 = -6 dB				
<b>ATKTH1-0</b>	Attack Theshold 00 = 0 dB 01 = -1 dB 10 = -2 dB 11 = -4 dB				
<b>RECTIME1-0</b>	Recovery Time Selection 00 = 32 ms 01 = 64 ms 10 = 128 ms 11 = 256 ms				
<b>ATKTIME</b>	Attack Timer Selection 0 = 1 ms 1 = 4 ms				

Table 90. ALC Control Register 3

	<b>ALC RESET</b>
	7,6,5,4,3,2,1,0
<b>ADDRESS = 1111101</b>	<b>Default = 0x00</b>
<b>ALC RESET</b>	A write to this register will restart the ALC operation. The value written to this register is irrelevant. A read from this register will give the gain reduction factor.

OUTLINE DIMENSIONS

Figure 41. 64-Lead Plastic Quad Flatpack [LQFP] (ST-64)  
Dimensions shown in inches and (millimeters)

ORDERING GUIDE

Model	Temperature Range	Control Interface	DAC Outputs	Package Options
ADAV802AST	-40°C to +85°C	SPI	Differential	ST-64
