

2048K x 8 SRAM Module

Features

- High-density 16-megabit SRAM modules
- High-speed CMOS SRAMs
 - Access time of 70 ns
- Low active power
 - 605 mW (max.), 2M x 8
- Double-sided SMD technology
- TTL-compatible inputs and outputs
- Small footprint SIP
 - PCB layout area of 0.72 sq. in.
- 2V data retention (L version)

Functional Description

The CYM1481A is a high-performance 16-megabit static RAM module organized as 2048K words by 8 bits. These modules

are constructed from four 512K x 8 SRAMs in plastic surface-mount packages on an epoxy laminate board with pins. On-board decoding selects one of the SRAMs from the high-order address lines, keeping the remaining devices in standby mode for minimum power consumption.

An active LOW write enable signal ($\overline{WE}$) controls the writing/reading operation of the memory. When $\overline{MS}$ and $\overline{WE}$ inputs are both LOW, data on the eight data input/output pins is written into the memory location specified on the address pins. Reading the device is accomplished by selecting the device and enabling the outputs $\overline{MS}$ and $\overline{OE}$ active LOW while $\overline{WE}$ remains inactive or HIGH. Under these conditions, the content of the location addressed by the information on the address pins is present on the eight data input/output pins.

The input/output pins remain in a high-impedance state unless the module is selected, outputs are enabled, and write enable ($\overline{WE}$) is HIGH.

Notes:

- Test conditions assume signal transition time of 10 μ s or less, timing reference levels of 1.5V, input pulse levels of 0 to 3.0V, output loading of 1 TTL load, and 100-pF load capacitance.
- t_{HZOE} , t_{HZMS} , and t_{HZWE} are specified with $C_L = 5$ pF as in part (b) of AC Test Loads and Waveforms. Transition is measured ± 500 mV from steady-state voltage.
- At any given temperature and voltage condition, t_{HZMS} is less than t_{LZMS} for any given device. These parameters are guaranteed and not 100% tested.
- The internal write time of the memory is defined by the overlap of $\overline{MS}$ LOW and $\overline{WE}$ LOW. Both signals must be LOW to initiate a write and either signal can terminate a write by going HIGH. The data input set-up and hold timing should be referenced to the rising edge of the signal that terminates the write.
