

Quad SPST JFET Analog Switch

T-51-11 SW-06

FEATURES

- Two Normally Open and Two Normally Closed SPST Switches with Disable
- Switches can be Easily Configured as a Dual SPDT or a DPDT
- Highly Resistant to Static Discharge Destruction
- Higher Resistance to Radiation Than Analog Switches Designed with MOS Devices
- Guaranteed R_{ON} Matching 10% Max
- Guaranteed Switching Speeds $T_{ON} = 500\text{ns}$ Max
..... $T_{OFF} = 400\text{ns}$ Max
- Guaranteed Break-Before-Make Switching
- Low "ON" Resistance 80 Ω Max
- Low R_{ON} Variation from Analog Input Voltage 5%
- Low Total Harmonic Distortion 0.01%
- Low Leakage Currents at High Temperature:
..... $T_A = 125^\circ\text{C}$ 100nA Max
..... $T_A = 85^\circ\text{C}$ 30nA Max
- Digital Inputs TTL/CMOS Compatible and Independent of V_+
- Improved Specifications and Pin Compatible to LF-11333/13333
- Dual or Single Power Supply Operation
- Available in Die Form

GENERAL DESCRIPTION

The SW-06 is a four channel single-pole, single-throw analog switch that employs both bipolar and ion-implanted FET devices. The SW-06 FET switches use bipolar digital logic inputs which are more resistant to static electricity than CMOS devices. Ruggedness and reliability are inherent in the SW-06 design and construction technology.

Increased reliability is complemented by excellent electrical specifications. Potential error sources are reduced by minimizing "ON" resistance and controlling leakage currents at high temperatures. The switching FET exhibits minimal R_{ON} variation over a 20V analog signal range and with power supply voltage changes. Operation from a single positive power supply voltage is possible. With $V_+ = 36\text{V}$, $V_- = 0\text{V}$, the analog signal range will extend from ground to +32V.

PNP logic inputs are TTL and CMOS compatible to allow the SW-06 to upgrade existing designs. The logic "0" and logic "1" input currents are at micro-ampere levels reducing loading on CMOS and TTL logic.

NOTES:

- $V_S = 0V$, $I_S = 100\mu A$. Specified as a percentage of $R_{AVERAGE}$ where:

$$R_{AVERAGE} = \frac{R_{ON1} + R_{ON2} + R_{ON3} + R_{ON4}}{4}$$
- Guaranteed by design.
- Switch is guaranteed by design to provide break-before-make operation.

- Current tested at $V_{IN} = 2.0V$. This is worst case condition.
- Switch being tested ON or OFF as indicated, $V_{INH} = 2.0V$ or $V_{INL} = 0.8V$, per logic truth table.
- Also applies to disable pin.
- Parameter tested only at $T_A = +125^\circ C$ for military grade devices.
- Guaranteed by R_{ON} and leakage tests. For normal operation maximum analog signal voltages should be restricted to less than $(V_+) - 4V$.

TYPICAL PERFORMANCE CHARACTERISTICS (OPERATING SINGLE SUPPLY)

NOTE: These single-supply-operation characteristic curves are valid when the negative power supply V^- is tied to the logic ground reference pin "GND". TTL input compatibility is still maintained when "GND" is the same potential as the TTL ground. t_{OFF} is measured from 50% of logic input waveform to 0.9 V_O . The analog voltage range extends from 0 to $V^+ - 4V$, the switch will no longer respond to logic control when V_A is within 4 volts of V^+ .

ANALOG CURRENT

The analog switches in the ON state are JFETs biased in their triode region and act as switches for analog current up to the I_A specification (see plot of I_{DS} vs V_{DS}). Some applications require pulsed currents exceeding the I_A spec. For example, an integrator reset switch discharging a shunt capacitor will produce a peak current of $I_{A(PEAK)} = V_{CAP}/R_{DS(ON)}$. In this application, it is best to connect the source to the most positive end of the capacitor, thereby achieving the lowest switch resistance and fastest reset times. The switch can easily handle any amount of capacitor discharge current subject only to the maximum heat dissipation of the package and the maximum operating junction temperature from which repetition rates can be established.

SWITCHING

Switching time t_{ON} and t_{OFF} characteristics are plotted versus V_{ANALOG} and temperature. In all cases, t_{OFF} is designed faster than t_{ON} to insure a break-before-make interval for SPDT and DPDT applications. The disable input (DIS) has the same switching times (t_{ON} and t_{OFF}) as the logic inputs (IN_X).

TYPICAL APPLICATIONS**OPERATION FROM SINGLE POSITIVE POWER SUPPLY**

Switching transients occurring at the source and drain contacts results from AC coupling of the switching FETs gate-to-source and gate-to-drain coupling capacitance. The switch turn ON will cause a negative going spike to occur and the turn OFF will cause a positive spike to occur. These spikes can be reduced by additional capacitance loading, lower values of R_L , or switching an additional switch (with its extra contact floating) to the opposite state connected to the spike sensitive node.

DISABLE NODE

This TTL compatible node is similar to the logic inputs IN_X but has an internal $2\mu A$ current source pull-up. If disable is left unconnected, it will assume the logic "1" state, then the state of the switches is controlled only by the logic inputs IN_X .

POWER SUPPLIES

This product operates with power supply voltages ranging from ± 12 to ± 18 volts; however, the specifications only guarantee device parameters with ± 15 volt $\pm 5\%$ power supplies. The power supply sensitive parameters have plots to indicate effects of supply voltages other than ± 15 volts.

Figure 1: Functional Applications of SW-06

APPLICATIONS INFORMATION

This single analog switch product configures, by appropriate pin connections, into four switch applications. As shown in Figure 1, the SW-06 connects as a QUAD SPST, a DUAL SPDT, a DUAL DPST, or a DPDT analog switch. This versatility increases further when taking advantage of the disable input (DIS) which turns all switches OFF when taken active low.

Ion-implantation of the JFET analog switch achieves low ON resistance and tight channel to channel matching. Combining the low ON resistance and low leakage currents results in a worst case voltage error figure $V_{\text{ERROR}} @ 125^{\circ}\text{C} = I_{\text{D(ON)}} \times R_{\text{SD(ON)}} = 100\text{nA} \times 100\Omega = 11\text{ microvolts}$. This amount of error is negligible considering dissimilar-metal thermally-induced offsets will be in the 5 to 15 microvolt range.

LOGIC INPUTS

The logic inputs (IN_x) and disable input (DIS) are referenced to a TTL logic threshold value of two forward diode drops (1.4V at 25°C) above the GND terminal. These inputs use PNP transistors which draw maximum current at a logic "0" level and drops to a leakage current of a reverse biased diode as the logic input voltage raises above 1.4 volts. Any logic input voltage greater than 2.0 volts becomes logic "1", less than 0.8 volts becomes logic "0" resulting in full TTL noise immunity not available from similar CMOS input analog

switches. The PNP transistor inputs require such low input current that the SW-06 approaches fan-ins of CMOS input devices. These bipolar logic inputs exceed any CMOS input circuit in resistance to static voltage and radiation susceptibility. No damage will occur to the SW-06 if logic high voltages are present when the SW-06 power supplies are OFF. When the V+ and V- supplies are OFF, the logic inputs present a reverse bias diode loading to active logic inputs. Input logic thresholds are independent of V+ and V- supplies making single V+ supply operation possible by simply connecting GND and V- together to the logic ground supply.

ANALOG VOLTAGE AND CURRENT

ANALOG VOLTAGE

These switches have constant ON resistance for analog voltages from the negative power supply (V-) to within 4 volts of the positive power supply. This characteristic shown in the plots results in good total harmonic distortion, especially when compared to CMOS analog switches that have a 20 to 30 percent variation in ON resistance versus analog voltage. Positive analog input voltages should be restricted to 4 volts less than V+ assuring the switch remains open circuit in the OFF state. No increase in switch ON resistance occurs when operating at supply voltages less than ±15 volts (see plot). Small signals have a 3dB down frequency of 70MHz (see insertion loss versus frequency plot).
