

Interfacing the MC68HC705J1A to 9356/9366 EEPROMs

By Mark Glenewinkel
CSIC Applications

INTRODUCTION

This application note describes the hardware and software interface used to communicate between the Freescale MC68HC705J1A MCU and 9356/9366 EEPROM chips. The 93XX series of EEPROMs are an industry standard used widely to store nonvolatile bits of information. The software listing in this application note will work with 9356 and 9366 EEPROMs. The EEPROM bits are arranged in 128 or 256 16-bit registers, respectively. With some modification, the software will work with other 93XX series EEPROMs.

Some of the applications in which EEPROMs can be utilized are listed below.

- ID number for remote addressing or security
- Storage of telecommunication information like phone number recall and speed dialing
- Power down information storage for consumer electronics like TVs and VCRs
- Reprogrammable calibration data for test/measurement equipment

The 93XX EEPROMs communicate with the outside world using a serial link. Since the MC68HC705J1A does not have the hardware on chip to communicate to the EEPROM, a software driver is used. This method bit programs an I/O port to properly transfer data to and from the EEPROM. A National NM93C56N was used for testing the software routines in this application note.

HARDWARE INTERFACE

The 9356 is a very simple 8-pin device. Appendix A shows a typical connection between the MC68HC705J1A and the 9356. The serial interface connection uses only four pins of the 9356. They are as follows:

- CS — Chip Select
- SK — Serial Clock
- DO — Serial Data Output
- DI — Serial Data Input

These signals must be clocked in a certain way in order to transfer the correct serial data to and from the MC68HC705J1A.

Freescale Semiconductor, Inc.

SOFTWARE INTERFACE

Communication between the MC68HC705J1A and the 9356 is done with a synchronous serial protocol. As mentioned earlier, the MC68HC705J1A bit programs its I/O pins to communicate with the 9356. A timing diagram of the serial link can be found in the 9356 data sheet if needed.

The 9356 will accept seven different commands. They are as follows:

- 1) READ — Read a 16-bit data word from an address in memory
- 2) WRITE — Write a 16-bit data word from an address in memory
- 3) WRALL — Write all addresses with the same 16-bit data word
- 4) ERASE — Erase a 16-bit data word from an address in memory
- 5) ERAL — Erase all addresses within the memory map
- 6) WEN — Erase/write enable the EEPROM memory
- 7) WDS — Erase/write disable the EEPROM memory

The 9356 transmission format is a frame of data bits containing an opcode, an address, and if needed, a word of data. The opcode is three bits long, the address is eight bits long, and the data word is 16 bits long. Table 1 illustrates the bit information each instruction needs.

Table 1.

Instruction	Opcode	Address	Data
READ	110	A7–A0	
WEN	100	11XXXXXX	
ERASE	111	A7–A0	
ERAL	100	10XXXXXX	
WRITE	101	A7–A0	D15–D0
WRALL	100	01XXXXXX	D15–D0
WDS	100	00XXXXXX	

IMPLEMENTATION AND TEST

Software was written to provide subroutines to perform each of the seven commands. A total of four bytes of RAM are needed to support the subroutines. These bytes are described below.

- 1) OP_CODE — Contains the opcode needed for the command
- 2) ADDR — Contains the address for the command
- 3) DATA_H — The high byte for the data word
- 4) DATA_L — The low byte for the data word

As needed, each EEPROM command subroutine will call other supporting subroutines to execute the transmission of data between the MC68HC705J1A and the 9356. Appendix B contains flowcharts for all of these subroutines.

Freescale Semiconductor, Inc.

Each EEPROM command subroutine has input data and output data. This data is inherent with some commands while others need the information passed to them before the subroutine is called. Table 2 lists the input data needed and output data generated for each of the seven commands.

Table 2:

Command	Subroutine Input	Subroutine Output
READ	ADDR	DATA_H/L
EWEN	—	—
ERASE	ADDR	—
ERAL	—	—
WRITE	ADDR & DATA_H/L	—
WRALL	DATA_H/L	—
EWDS	—	—

Code was written and tested with a level of quality equal to the Carnegie-Mellon Software Engineering Institute (SEI) Level 2. A test routine consisting of writing and reading the EEPROM is listed in Appendix C. Refer to Appendix A for the schematic used in the design and test of the software. An LED is used to verify that the test code works properly. The test routine executes the following:

- 1) Initializes the port on the HC705J1A for serial transmission. LED is turned off.
- 2) Writes EEPROM address \$00 with \$AA55.
- 3) Writes EEPROM address \$20 with \$1234.
- 4) Reads EEPROM address \$00 and stores it to RAM location TEST1 and TEST2.
- 5) Reads EEPROM address \$20 and stores it to RAM location TEST3 and TEST4.
- 6) Checks if TEST1 = \$AA, TEST2 = \$55, TEST3 = \$12, and TEST4 = \$34.
- 7) If check is good, then light the LED. If check is bad, do not light the LED.
- 8) Continue to run in an infinite loop until reset.

For increased reliability, the software watchdog on the MC68HC705J1A is used. Also, a low voltage inhibit circuit, the MC34064, is used to decrease susceptibility to brown out or short power failure conditions.

SUMMARY

This application note has described the interface needed to successfully communicate between the MC68HC705J1A and the 9356. For more information on the MC68HC705J1A, please consult the Technical Data Manual, MC68HC705J1A/D. Contact National Semiconductor or SGS Thompson for technical data on the 93XX series of EEPROM memories.

An electronic copy of the code listing in Appendix C and a listing of the test program to fully test all the EEPROM commands can be found on the Freescale MCU BBS. The BBS number is (512) 891-3733. The filename is j1a_9356.arc and is on the CSIC BBS under the APPNOTES directory.

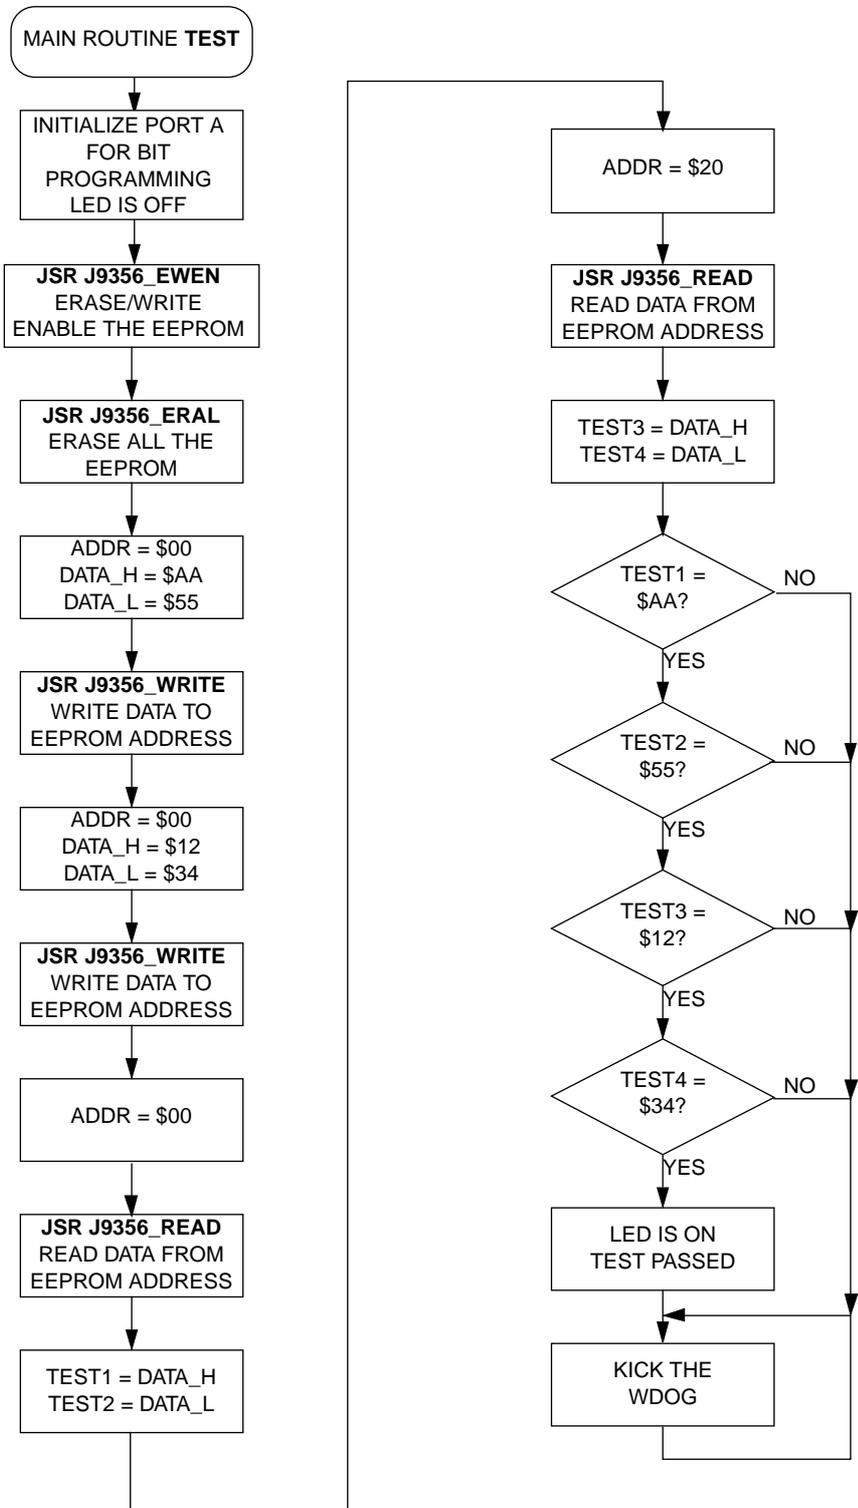

Also, Freescale Application Note AN1221/D further details the software and hardware interfaces needed between the 93XX series and other HC05 MCUs.
