 HIGH PERFORMANCE ANALOG INTEGRATED CIRCUITS

EL400/EL400C

T-79-07-10

200 MHz Current Feedback Amplifier

ELANTEC INC

EL400/EL400C

Features

- 200 MHz -3 dB bandwidth, $A_V = 2$
- 12 ns settling to 0.05%
- $V_S = \pm 5V$ @ 15 mA
- Low distortion: HD2, HD3 @ -60 dBc at 20 MHz
- Differential gain 0.02% at NTSC, PAL
- Differential phase 0.01° at NTSC, PAL
- Overload/short-circuit protected
- ± 1 to ± 8 closed-loop gain range
- Low cost
- Direct replacement for CLC400

Applications

- Video gain block
- Video distribution
- HDTV amplifier
- High-speed A/D conversion
- D/A I-V conversion
- Photodiode, CCD preamps
- IF processors
- High-speed communications

Ordering Information

Part No.	Temp. Range	Package	Outline #
EL400CN	-40°C to +85°C	8-Pin P-DIP	MDP0031
EL400CS	-40°C to +85°C	8-Lead SO	MDP0027
EL400J/883B	-55°C to +125°C	8-Pin CerDIP	MDP0010

5962-8997001 is the SMD version of this device.

General Description

The EL400 is a wide bandwidth, fast settling monolithic amplifier built using an advanced complementary bipolar process. This amplifier uses current-mode feedback to achieve more bandwidth at a given gain than conventional operational amplifiers. Designed for closed-loop gains of ± 1 to ± 8 , the EL400 has a 200 MHz -3 dB bandwidth ($A_V = +2$), and 12 ns settling to 0.05% while consuming only 15 mA of supply current.

The EL400 is an obvious high-performance solution for video distribution and line-driving applications. With low 15 mA supply current, differential gain/phase of 0.02%/0.01°, and a minimum 50 mA output drive, performance in these areas is assured.

The EL400's settling to 0.05% in 12 ns, low distortion, and ability to drive capacitive loads make it an ideal flash A/D driver. The wide 200 MHz bandwidth and extremely linear phase allow unmatched signal fidelity. D/A systems can also benefit from the EL400, especially if linearity and drive levels are important.

Elantec products and facilities comply with MIL-STD-883 Revision C, MIL-I-45208A, and other applicable quality specifications. For information on Elantec's military processing, see Elantec document, *QRA-2: Elantec's Military Processing, Monolithic Integrated Circuits*.

All parameters having Min/Max specifications are guaranteed. The Test Level column indicates the specific device testing actually performed during production and Quality inspection. Elantec performs most electrical tests using modern high-speed automatic test equipment, specifically the LTX77 Series system. Unless otherwise noted, all tests are pulsed tests, therefore $T_J = T_C = T_A$.

Test Level	Test Procedure
I	100% production tested and QA sample tested per QA test plan QCX0002.
II	100% production tested at $T_A = 25^\circ\text{C}$ and QA sample tested at $T_A = 25^\circ\text{C}$, T_{MAX} and T_{MIN} per QA test plan QCX0002.
III	QA sample tested per QA test plan QCX0002.
IV	Parameter is guaranteed (but not tested) by Design and Characterization Data.
V	Parameter is typical value at $T_A = 25^\circ\text{C}$ for information purposes only.

Open Loop DC Electrical Characteristics $V_S = \pm 5\text{V}$, $R_L = 100\Omega$ unless otherwise specified

Applications Information

Theory of Operation

The EL400 has a unity gain buffer from the non-inverting input to the inverting input. The error signal of the EL400 is a current flowing into (or out of) the inverting input. A very small change in current flowing through the inverting input will cause a large change in the output voltage. This current amplification is called the transimpedance (R_{OL}) of the EL400 [$V_{OUT} = (R_{OL}) * (-I_{IN})$]. Since R_{OL} is very large, the current flowing into the inverting input in the steady-state (non-slewing) condition is very small.

Therefore we can still use op-amp assumptions as a first-order approximation for circuit analysis, namely that:

1. The voltage across the inputs is approximately 0V.
2. The current into the inputs is approximately 0 mA.

Resistor Value Selection and Optimization

The value of the feedback resistor (and an internal capacitor) sets the AC dynamics of the

EL400. The nominal value for the feedback resistor is 250Ω, which is the value used for production testing. This value guarantees stability. For a given closed-loop gain the bandwidth may be increased by decreasing the feedback resistor and, conversely, the bandwidth may be decreased by increasing the feedback resistor.

Reducing the feedback resistor too much will result in overshoot and ringing, and eventually oscillations. Increasing the feedback resistor results in a lower -3 dB frequency. Attenuation at high frequency is limited by a zero in the closed-loop transfer function which results from stray capacitance between the inverting input and ground. Consequently, it is very important to keep stray capacitance to a minimum at the inverting input.

Differential Gain/Phase

An industry-standard method of measuring the distortion of a video component is to measure the amount of differential gain and phase error it introduces. To measure these, a 40 IRE_{pp} reference signal is applied to the device with 0V DC offset (0IRE) at 3.58 MHz for NTSC, 4.43 MHz for

EL400/EL400C

ELANTEC INC

200 MHz Current Feedback Amplifier**Applications Information — Contd.**

PAL, and 30 MHz for HDTV. A second measurement is then made with a 0.714V DC offset (100IRE). Differential Gain is a measure of the change in amplitude of the sine wave, and is measured in percent. Differential Phase is a measure of the change in phase, and is measured in degrees. Typically, the maximum positive and negative deviations are summed to give peak values.

In general, a back terminated cable (75 Ω in series at the drive end and 75 Ω to ground at the receiving end) is preferred since the impedance match at both ends will absorb any reflections. However, when double-termination is used, the received signal is reduced by half; therefore a gain of 2 configuration is typically used to compensate for the attenuation. In a gain of 2 configuration, with output swing of 2 V_{pp}, with each back-terminated load at 150 Ω . The EL400 is capable of driving up to 4 back-terminated loads with excellent video performance. Please refer to the typical curves for more information on video performance with respect to frequency, gain, and loading.

Capacitive Feedback

The EL400 relies on its feedback resistor for proper compensation. A reduction of the impedance of the feedback element results in less stability, eventually resulting in oscillation. Therefore, circuit implementations which have capacitive feedback should not be used because of the capacitor's impedance reduction with frequency. Similarly, oscillations can occur when using the technique

of placing a capacitor in parallel with the feedback resistor to compensate for shunt capacitances from the inverting input to ground.

Offset Adjustment Pin

Output offset voltage of the EL400 can be nulled by tying a 10k potentiometer between +V_S and -V_S with the slider attached to pin 1. A full-range variation of the voltage at pin 1 to $\pm 5V$ results in an offset voltage adjustment of at least ± 10 mV. For best settling performance pin 1 should be bypassed to ground with a ceramic capacitor located near to the package, even if the offset voltage adjustment feature is not being used.

Printed Circuit Layout

As with any high frequency device, good PCB layout is necessary for optimum performance. Ground plane construction is a requirement, as is good power-supply and Offset Adjust bypassing close to the package. The inverting input is sensitive to stray capacitance, therefore connections at the inverting input should be minimal, close to the package, and constructed with as little coupling the ground plane as possible.

Capacitance at the output node will reduce stability, eventually resulting in peaking, and finally oscillation if the capacitance is large enough. The design of the EL400 allows a larger capacitive load than comparable products, yet there are occasions when a series resistor before the capacitance may be needed. Please refer to the graphs to determine the proper resistor value needed.
