

## Stereo 2-W Audio Power Amplifier (with DC\_Volume Control)

### Features

- **Low Operating Current with 14mA**
- **Improved Depop Circuitry to Eliminate Turn-on and Turn-off Transients in Outputs**
- **High PSRR**
- **32 Steps Volume Adjustable by DC Voltage with Hysteresis**
- **2W Per Channel Output Power into 4W Load at 5V, BTL Mode**
- **Two Output Modes Allowable with BTL and SE Modes Selected by SE/BTL Pin**
- **Low Current Consumption in Shutdown Mode (50mA)**
- **Short Circuit Protection**
- **Power off Depop Circuit Integration**
- **TSSOP-24P with or without Thermal Pad Package**
- **Lead Free and Green Devices Available (RoHS Compliant)**

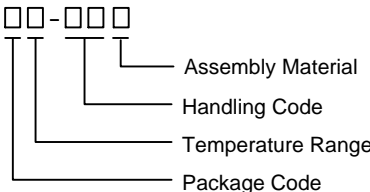

### General Description

APA2120/1 is a monolithic integrated circuit, which provides precise DC volume control, and a stereo bridged audio power amplifiers is capable of producing 2.7W(2.0W) into 3Ω with less than 10% (1.0%)THD+N. The attenuator range of the volume control in APA2120/1 is from 20dB (DC\_Vol=0V) to -80dB (DC\_Vol=3.54V) with 32 steps. The advantage of internal gain setting can be less components and PCB area. Both of the depop circuitry and the thermal shutdown protection circuitry are integrated in APA2120/1 and reduce pops and clicks noise during power up or shutdown mode operation. It also improves the power off pop noise and protects the chip from being destroyed by over temperature and short current failure. To simplify the audio system design, APA2120/1 combines a stereo bridge-tied loads (BTL) mode for speaker drive and a stereo single-end (SE) mode for head-phone drive into a single chip, where both modes are easily switched by the SE/BTL input control pin signal. Besides, the multiple input selection is used for portable audio system.

### Applications

- **NoteBook PC**
- **LCD Monitor or TV**

Note: ANPEC lead-free products contain molding compounds/die attach materials and 100% matte tin plate termination finish; which are fully compliant with RoHS. ANPEC lead-free products meet or exceed the lead-free requirements of IPC/JEDEC J-STD-020C for MSL classification at lead-free peak reflow temperature. ANPEC defines "Green" to mean lead-free (RoHS compliant) and halogen free (Br or Cl does not exceed 900ppm by weight in homogeneous material and total of Br and Cl does not exceed 1500ppm by weight).

ANPEC reserves the right to make changes to improve reliability or manufacturability without notice, and advise customers to obtain the latest version of relevant information to verify before placing orders.

## Application Information

### BTL Operation

The APA2120/1 output stage (power amplifier) has two pairs of operational amplifiers internally, allowed for different amplifier configurations.

Figure 1 : APA2120/1 Internal Configuration. (each channel)

The power amplifier's OP1 gain is setting by internal unity-gain and the input audio signal comes from the internal volume control amplifier while the second amplifier OP2 is internally fixed in a unity-gain, inverting configuration. Figure 1 shows that the output of OP1 is connected to the input to OP2, which results in the output signals of both amplifiers with identical in magnitude, but out of phase 180°. Consequently, the differential gain for each channel is 2 x (Gain of SE mode).

By driving the load differentially through outputs OUT+ and OUT-, an amplifier configuration commonly referred to bridged mode is established. The BTL mode operation is different from the classical single-ended SE amplifier configuration where one side of its load is connected to the ground.

A BTL amplifier design has a few distinct advantages over the SE configuration, as it provides differential drive to the load, thus doubling the output swing for a specified supply voltage.

When placed under the same conditions, a BTL amplifier has four times the output power of a SE amplifier. A BTL configuration, such as the one used in APA2120/1, also creates a second advantage over SE amplifiers. Since the differential outputs, ROUT+, ROUT-, LOUT+, and LOUT-, are biased at half-supply, it's not necessary for DC voltage to be across the load. This eliminates the need for an output coupling capacitor which is required in a single supply, SE configuration.

### Single-Ended Operation

Consider the single-supply SE configuration shown Application Circuit. A coupling capacitor is required to block the DC offset voltage from reaching the load. These capacitors can be quite large (approximately 33µF to 1000µF) so they tend to be expensive, occupied valuable PCB area, and have the additional drawback of limiting low-frequency performance of the system (refer to the Output Coupling Capacitor). The rules described still hold with the addition of the following relationship:

$$\frac{1}{C_{bypass} \times 125k\Omega} \leq \frac{1}{R_i C_i} \ll \frac{1}{R_L C_c} \quad (1)$$

### Output SE/BTL Operation

The best cost saving feature of APA2120/1 is that they can be switched easily between BTL and SE modes. This feature eliminates the requirement for an additional headphone amplifier in applications where internal stereo speakers are driven in the BTL mode but external headphone or speakers must be accommodated. Internal to the APA2120/1, two separate amplifiers drive OUT+ and OUT- (see Figure 1). The SE/BTL input controls the operation of the follower amplifier that drives LOUT- and ROUT-.

- When SE/BTL is held low, the OP2 is turned on and the APA2120/1 is in the BTL mode.
- When SE/BTL is held high, the OP2 is in a high output impedance state, which configures the APA2120/1 as SE driver from OUT+. I<sub>DD</sub> is reduced by approximately one-half in SE mode.

The control of the SE/BTL input can be a logic-level TTL source, a resistor divider network, or the stereo headphone jack with switch pin as shown in the Application Circuit.

Figure 2 : SE/BTL Input Selection by Phonejack Plug.

## Application Information (Cont.)

### Output SE/BTL Operation (Cont.)

In Figure 2, input SE/BTL operates as below :

When the phonejack plug is inserted, the 1kΩ resistor is disconnected and the SE/BTL input is pulled high and enables the SE mode. When the input goes to a high level, the OUT- amplifier is shutdown which causes the speaker to mute. Then, the OUT+ amplifier drives through the output capacitor (C<sub>o</sub>) into the headphone jack. When there is no headphone plugged into the system, the contact pin of the headphone jack is connected from the signal pin, and the voltage divider set up by resistors 100kΩ and 1kΩ. Resistor 1kΩ then pulls low the SE/BTL pin, enabling the BTL function.

### Volume Control Function

APA2120/1 have an internal stereo volume control that setting is the function of the DC voltage applied to the VOLUME input pin. The APA2120/1 volume control consists of 32 steps that are individually selected by a variable DC voltage level on the VOLUME control pin. The range of the steps, controlled by the DC voltage, are from 20dB to -80dB. Each gain step corresponds to a specific input voltage range as shown in table. To minimize the effect of noise on the volume control pin, which can affect the selected gain level, hysteresis and clock delay are implemented. The amount of hysteresis corresponds to half of the step width is shown in the volume control graph.

Figure 3 : Gain setting vs VOLUME Pin Voltage.

For the highest accuracy, the voltage is shown in the 'recommended voltage' column of the table and used to select a desired gain. This recommended voltage is exactly halfway between the two nearest transitions. The gain levels are 2dB/step from 20dB to -40dB in BTL mode, and the last step at -80dB as mute mode.

### Input Resistance, Ri

The gain for each audio input of the APA2120/1 is set by the internal resistors (R<sub>i</sub> and R<sub>f</sub>) of volume control amplifier in inverting configuration.

$$SE \text{ Gain} = A_v = -\frac{R_f}{R_i} \tag{2}$$

$$BTL \text{ Gain} = -2 \times \frac{R_f}{R_i} \tag{3}$$

BTL mode operation brings the factor of 2 in the gain equation due to the inverting amplifier mirroring the voltage swing across the load. For the varying gain setting, APA2120/1 generate each input resistance on the figure 4. The input resistance will affect the low frequency performance of audio signal. The minimum input resistance is 10kΩ when gain setting is 20dB, and the resistance will ramp up when close loop gain below 20dB. The input resistance has wide variation (+/-10%) caused by the process variation.

Figure 4: Input Resistance vs Gain Setting.

## Application Information (Cont.)

### Input Capacitor, Ci

In the typical application, an input capacitor, Ci, is required to allow the amplifier to bias the input signal to the proper DC level for optimum operation. In this case, Ci and the minimum input impedance Ri (10kΩ) form a high-pass filter with the corner frequency determined in the following equation :

$$F_c(\text{highpass}) = \frac{1}{2\pi \times 10k\Omega \times C_i} \quad (4)$$

The value of Ci is important to consider as it directly affects the low frequency performance of the circuit. Consider the example where Ri is 10kΩ and the specification calls for a flat bass response down to 100Hz. Equation is reconfigured as below :

$$C_i = \frac{1}{2\pi \times 10k\Omega \times f_c} \quad (5)$$

When the input resistance variation is considered, the Ci is 0.16μF. Therefore, a value in the range of 0.22μF to 1.0μF would be chosen.

A further consideration for this capacitor is the leakage path from the input source through the input network (Ri+Rf, Ci) to the load. This leakage current creates a DC offset voltage at the input to the amplifier that reduces useful headroom, especially in high gain applications. For this reason, a low-leakage tantalum or ceramic capacitor is the best choice. When polarized capacitors are used, the positive side of the capacitor should face the amplifier input in most applications as the DC level there is held at V<sub>DD</sub>/2, which is likely higher than the source DC level. Please note that it is important to confirm the capacitor polarity in the application.

### Effective Bypass Capacitor, Cbypass

As other power amplifiers, proper supply bypassing is critical for low noise performance and high power supply rejection.

The capacitors located on both the bypass and power supply pins should be as close to the device as possible. The effect of a larger bypass capacitor will improve PSRR due to increased supply stability. Typical applications employ a 5V regulator with 1.0μF and a 0.1μF bypass capacitor as supply filtering. This does not eliminate the need

for bypassing the supply nodes of the APA2120/1. The selection of bypass capacitors, especially Cbypass, is thus dependent upon desired PSRR requirements, click and pop performance.

On the chip, there are three bypass pins for used, and they are tied together in the internal circuit.

The effective capacitance is the Cbypass=(Cb//CLbyasss/CRbypass). When absolute minimum cost and/or component space is required, one bypass capacitor can be used.

To avoid the start-up pop noise, the bypass voltage should rise slower than the input bias voltage and the relationship shown in equation (6) should be maintained.

$$\frac{1}{C_{\text{bypass}} \times 125k\Omega} \ll \frac{1}{100k\Omega \times C_i} \quad (6)$$

The bypass capacitor is fed from a 125kΩ resistor inside the amplifier and the 100kΩ is maximum input resistance of (Ri+ Rf). Bypass capacitor, Cb, values of 3.3μF to 10μF ceramic or tantalum low-ESR capacitors are recommended for the best THD and noise performance.

The bypass capacitance also effects to the start up time. It is determined in the following equation :

$$T_{\text{start up}} = 5 \times (C_{\text{bypass}} \times 125k\Omega) \quad (7)$$

### Output Coupling Capacitor, Cc

In the typical single-supply SE configuration, an output coupling capacitor (Cc) is required to block the DC bias at the output of the amplifier thus preventing DC currents in the load. As with the input coupling capacitor, the output coupling capacitor and impedance of the load form a high-pass filter governed by the following equation:

$$F_c(\text{highpass}) = \frac{1}{2\pi R_L C_c} \quad (8)$$

For example, a 330μF capacitor with an 8Ω speaker would attenuate low frequencies below 60.6Hz. The main disadvantage of performance is that the load impedance is typically small, which drives the low-frequency corner higher degrading the bass response. Large values of C<sub>c</sub> are required to pass low frequencies into the load.

## Application Information (Cont.)

### Power Supply Decoupling, Cs

The APA2120/1 provide  $PV_{DD}$  and  $V_{DD}$  two independent power inputs for used.  $PV_{DD}$  is used for power amplifier only and  $V_{DD}$  is used for volume control amplifier and internal circuit excepting power amplifier. The APA2120/1 are high-performance CMOS audio amplifiers that requires adequate power supply decoupling to ensure the output total harmonic distortion (THD) is as low as possible. Power supply decoupling also prevents the oscillations being caused by long lead length between the amplifier and the speaker. The optimum decoupling is achieved by using two different types of capacitors that target on different noise on the power supply leads.

For higher frequency transients, spikes, or digital hash on the line, a good low equivalent-series-resistance(ESR) ceramic capacitor, typically 0.1 $\mu$ F placed as close as possible to the device  $V_{DD}$  and  $PV_{DD}$  lead works the best. For filtering lower-frequency noise signals, a large aluminum electrolytic capacitor of 10 $\mu$ F or greater placed near the audio power amplifier is recommended.

### Optimizing Depop Circuitry

Circuitry has been included in the APA2120/1 to minimize the amount of popping noise at power-up and when coming out of shutdown mode. Popping occurs whenever a voltage step is applied to the speaker. In order to eliminate clicks and pops, all capacitors must be fully discharged before turn-on. Rapid on/off switching of the device or the shutdown function will cause the click and pop circuitry.

The value of  $C_i$  will also affect turn-on pops. (Refer to Effective Bypass Capacitance) The bypass voltage should rises slower than input bias voltage. Although the bypass pin current source cannot be modified, the size of  $C_{bypass}$  can be changed to alter the device turn-on time and the amount of clicks and pops. By increasing the value of  $C_{bypass}$ , turn-on pop can be reduced. However, the tradeoff for using a larger bypass capacitor is to increase the turn-on time for this device. There is a linear relationship between the size of  $C_{bypass}$  and the turn-on time. In a SE configuration, the output coupling capacitor,  $C_c$ , is of particular concern.

This capacitor discharges through the internal 10k $\Omega$  resistors. Depending on the size of  $C_c$ , the time constant can be relatively large. To reduce transients in SE mode, an external 1k $\Omega$  resistor can be placed in parallel with the internal 10k $\Omega$  resistor. The tradeoff for using this resistor is an increase in quiescent current. In most cases, choosing a small value of  $C_i$  in the range of 0.33 $\mu$ F to 1 $\mu$ F,  $C_b$  being equal to 4.7 $\mu$ F and an external 1k $\Omega$  resistor should be placed in parallel, and the internal 10k $\Omega$  resistor should produce a virtually clickless and popless turn-on.

A high gain amplifier intensifies the problem as the small delta in voltage is multiplied by the gain. So it is advantageous to use low-gain configurations.

### Shutdown Function

In order to reduce power consumption while not in use, the APA2120/1 contain a shutdown pin to externally turn off the amplifier bias circuitry. This shutdown feature turns the amplifier off when a logic low is placed on the SHUTDOWN pin. The trigger point between a logic high and logic low level is typically 2.0V. It is best to switch between the ground and the supply  $V_{DD}$  to provide maximum device performance.

By switching the SHUTDOWN pin to low, the amplifier enters a low-current state,  $I_{DD} < 50\mu$ A. APA2120/1 is in shutdown mode, except PC-BEEP detect circuit. Under normal operation, SHUTDOWN pin pulls to high level to keep the IC out of the shutdown mode. The SHUTDOWN pin should be tied to a definite voltage to avoid unwanted state changing.

### Input HP/LINE Operation

APA2120/1 amplifiers have two separate inputs for each of the left and right stereo channels. The APA2120 and APA2121 have different control input by SE/BTL and HP/LINE, respectively.

APA2120 internal multiplexor is selected by SE/BTL control input. Refer to the 'Output SE/BTL Operation', the voltage divider of 100k $\Omega$  and 1k $\Omega$  sets the voltage at the SE/BTL pin to be approximately 50mV when no phonejack plugged into the system.

## Application Information (Cont.)

### Input HP/LINE Operation (Cont.)

This logic-low voltage at the SE/BTL pin makes APA2120 into LINE input mode operation. It becomes HP input mode when phonejack plugged.

An internal multiplexor selects the input to connect to the amplifier based on the state of the HP/LINE pin of the APA2121.

- To select the LINE inputs, set HP/LINE pin to a low level.
- To enable the HP(headphone) inputs, set HP/LINE pin to a high level.

As APA2121, HP/LINE input multiplexor and SE/BTL output operating mode have independent control paths, which can be used for multiple audio input system. This function will be the same as APA2120 when HP/LINE and SE/BTL are tied together.

### PC-BEEP Detection

APA2120/1 integrate a BEEP detect circuit for NOTEBOOK PC. When BEEP signal is provided on the PCBEEP input pin, the BEEP mode is active. APA2120/1 will force to BTL mode and the internal gain is fixed at -10dB. The PCBEEP signal becomes the amplifier input signal and plays on the speaker without coupling capacitor. It will be out of shutdown mode whenever BEEP mode is enabled. APA2120/1 will return to previous setting when it is out of BEEP mode. The input impedance is 100kΩ on the PCBEEP input pin.

APA2120 provide extra PCBEN control input signal to force IC into BEEP mode. The BEEP mode will be enabled when PCBEN goes to a high level. When the BEEP mode is overridden, the signal from the PCBEEP will pass to speaker directly.

### Clock Generator

APA2120/1 integrate a clock block to avoid volume control function abnormal when VOLUME control signal with spike or noise. APA2120/1 change each step of volume gain after four clock cycles make sure control signal ready. It provides 130kHz frequency if no capacitor is placed on CLK pin to the ground. The larger capacitance will slow down the and clock frequency. A capacitor 33nF between CLK to the ground and will generate 147Hz frequency on the CLK pin.

### BTL Amplifier Efficiency

An easy-to-use equation to calculate efficiency starts out as being equal to the ratio of power from the power supply to the power delivered to the load.

The following equations are the basis for calculating amplifier efficiency.

$$\text{Efficiency} = \frac{P_O}{P_{SUP}} \quad (9)$$

Where :

$$P_O = \frac{V_{ORMS} \times V_{ORMS}}{R_L} = \frac{V_P \times V_P}{2R_L}$$

$$V_{ORMS} = \frac{V_P}{\sqrt{2}} \quad (10)$$

$$P_{SUP} = V_{DD} \times I_{DDAVG} = V_{DD} \times \frac{2V_P}{\pi R_L} \quad (11)$$

Table 1 Calculates Efficiencies for Four Different Output Power Levels.

Note that the efficiency of the amplifier is quite low for lower power levels and rises sharply as power to the load is increased resulting in a nearly flat internal power dissipation over the normal operating range. Note that the internal dissipation at full output power is less than the dissipation in the half power range. Calculating the efficiency for a specific system is the key to proper power supply design. For a stereo 1W audio system with 8Ω loads and a 5V supply, the maximum draw on the power supply is almost 3W.

A final point to remember about linear amplifiers (either SE or BTL) is how to manipulate the terms in the efficiency equation to an utmost advantage when possible. Note that in equation,  $V_{DD}$  is in the denominator. This indicates that as  $V_{DD}$  goes down, efficiency goes up. In other words, use the efficiency analysis to choose the correct supply voltage and speaker impedance for the application.

Po (W)	Efficiency (%)	I <sub>DD</sub> (A)	V <sub>PP</sub> (V)	P <sub>D</sub> (W)
0.25	31.25	0.16	2.00	0.55
0.50	47.62	0.21	2.83	0.55
1.00	66.67	0.30	4.00	0.5
1.25	78.13	0.32	4.47	0.35

\*\*High peak voltages cause the THD to increase.

Table 1. Efficiency Vs Output Power in 5-V/8Ω BTL Systems

## Application Information (Cont.)

### Power Dissipation

Whether the power amplifier is operated in BTL or SE modes, power dissipation is a major concern. Equation 13 states the maximum power dissipation point for a SE mode operating at a given supply voltage and driving a specified load.

$$\text{SE mode : } P_{D,MAX} = \frac{V_{DD}^2}{2\pi^2 R_L} \quad (13)$$

In BTL mode operation, the output voltage swing is doubled as in SE mode. Thus, the maximum power dissipation point for a BTL mode operating at the same given conditions is 4 times as in SE mode.

$$\text{BTL mode : } P_{D,MAX} = \frac{4V_{DD}^2}{2\pi^2 R_L} \quad (14)$$

Since the APA2120/1 are dual channel power amplifiers, the maximum internal power dissipation is 2 times that both of equations depend on the mode of operation. Even this substantial increase in power dissipation, the APA2120/1 do not require extra heatsink. The power dissipation from equation 14, assuming a 5V-power supply and an 8Ω load, must not be greater than the power dissipation that results from the equation 15 :

$$P_{D,MAX} = \frac{T_{J,MAX} - T_A}{\theta_{JA}} \quad (15)$$

For TSSOP-24 package with thermal pad, the thermal resistance ( $\theta_{JA}$ ) is equal to 45°C/W.

Since the maximum junction temperature ( $T_{J,MAX}$ ) of APA2120/1 are 150°C and the ambient temperature ( $T_A$ ) are defined by the power system design, the maximum power dissipation which the IC package is able to handle can be obtained from equation 16.

Once the power dissipation is greater than the maximum limit ( $P_{D,MAX}$ ), either the supply voltage ( $V_{DD}$ ) must be decreased, the load impedance ( $R_L$ ) must be increased or the ambient temperature should be reduced.

### Thermal Pad Consideration

The thermal pad must be connected to the ground. The package with thermal pad of the APA2120/1 require special attention on thermal design. If the thermal design issues are not properly addressed, the APA2120/1 4Ω will go into thermal shutdown when driving a 4Ω load.

The thermal pad on the bottom of the APA2120/1 should be soldered down to a copper pad on the circuit board. Heat can be conducted away from the thermal pad through the copper plane to ambient. If the copper plane is not on the top surface of the circuit board, 8 to 10 vias of 13 mil or smaller in diameter should be used to thermally couple the thermal pad to the bottom plane.

For good thermal conduction, the vias must be plated through and solder filled. The copper plane used to conduct heat away from the thermal pad should be as large as practical.

If the ambient temperature is higher than 25°C, a larger copper plane or forced-air cooling will be required to keep the APA2120/1 junction temperature below the thermal shutdown temperature (150°C). In higher ambient temperature, higher airflow rate and/or larger copper area will be required to keep the IC out of the thermal shutdown.
