LTC5592

## fGATURES

- Conversion Gain: 8.3 dB at 2.35 GHz
- IIP3: 27.3 dBm at 2.35 GHz
- Noise Figure: 9.8 dB at 2.35 GHz
- 15.3dB NF Under 5dBm Blocking
- High Input P1dB
- 47dB Channel-to-Channel Isolation
- 3.3V Supply, 1.3W Power Consumption
- Low Power Mode for O.8W Consumption
- Independent Channel Shutdown Control
- $50 \Omega$ Single-Ended RF and LO Inputs
- LO Input Matched In All Modes
- OdBm LO Drive Level
- Small Package and Solution Size
- $-40^{\circ} \mathrm{C}$ to $105^{\circ} \mathrm{C}$ Operation

## APPLICATIONS

- 3G/4G Wireless Infrastructure Diversity Receivers (LTE, W-CDMA, TD-SCDMA, WiMAX, GSM 1800)
- MIMO Infrastructure Diversity Receivers
- High Dynamic Range Downmixer Applications

Dual 1.6 GHz to 2.7 GHz High Dynamic Range Downconverting Mixer DESCRIPTIOn

The LTC®5592 is part of a family of dual-channel high dynamic range, high gain downconverting mixers covering the 600 MHz to 4.5 GHz RF frequency range. The LTC5592 is optimized for 1.6 GHz to 2.7 GHz RF applications. The LO frequency must fall within the 1.7 GHz to 2.5 GHz range for optimum performance. A typical application is a LTE or WiMAX receiver with a 2.3 GHz to 2.7 GHz RF input and low side LO.

The LTC5592's high conversion gain and high dynamic range enable the use of lossy IF filters in high selectivity receiver designs, while minimizing the total solution cost, board space and system-level variation. A low current mode is provided for additional power savings and each of the mixer channels has independent shutdown control.

High Dynamic Range Dual Downconverting Mixer Family

| PART NUMBER | RF RANGE | LO RANGE |
| :---: | :---: | :---: |
| LTC5590 | 600 MHz to 1.7 GHz | 700 MHz to 1.5 GHz |
| LTC5591 | 1.3 GHz to 2.3 GHz | 1.4 GHz to 2.1 GHz |

Note 1: Stresses beyond those listed under Absolute Maximum Ratings may cause permanent damage to the device. Exposure to any Absolute Maximum Rating condition for extended periods may affect device reliability and lifetime.
Note 2: The LTC5592 is guaranteed functional over the case operating temperature range of $-40^{\circ} \mathrm{C}$ to $105^{\circ} \mathrm{C}\left(\theta_{\mathrm{JC}}=7^{\circ} \mathrm{C} / \mathrm{W}\right)$.

Note 3: SSB Noise Figure measured with a small-signal noise source, bandpass filter and 6dB matching pad on RF input, bandpass filter and 6 dB matching pad on the LO input, and no other RF signals applied.
Note 4: Channel $A$ to channel $B$ isolation is measured as the relative IF output power of channel $B$ to channel $A$, with the RF input signal applied to channel $A$. The RF input of channel $B$ is $50 \Omega$ terminated and both mixers are enabled.

## PIn fUnCTIOnS

RFA, RFB (Pins 1, 6): Single-Ended RF Inputs for Channels $A$ and $B$. These pins are internally connected to the primary sides of the RF input transformers, which have low DC resistance to ground. Series DC-blocking capacitors should be used to avoid damage to the integrated transformer when DC voltage is present at the RF inputs. The RF inputs are impedance matched when the LO input is driven with a $0 \pm 6 \mathrm{dBm}$ source between 1.7 GHz and 2.5 GHz and the channels are enabled.

CTA, CTB (Pins 2, 5): RF Transformer Secondary CenterTap on Channels A and B. These pins may require bypass capacitors to ground to optimize IIP3 performance. Each pin has an internally generated bias voltage of 1.2 V and must be DC-isolated from ground and $\mathrm{V}_{\mathrm{CC}}$.
GND (Pins 3, 4, 7, 13, 15, 24, Exposed Pad Pin 25): Ground. These pins must be soldered to the RF ground plane on the circuit board. The exposed pad metal of the package provides both electrical contact to ground and good thermal contact to the printed circuit board.
IFGNDB, IFGNDA (Pins 8, 23): DC Ground Returns for the IF Amplifiers. These pins must be connected to ground to complete the DC current paths for the IF amplifiers. Chip inductors may be used to tune LO-IF and RF-IF leakage. Typical DC current is 101 mA for each pin.

IFB ${ }^{+}$, IFB $^{-}$, IFA $^{-}$, IFA+ (Pins 9, 10, 21, 22): Open-Collector Differential Outputs for the IFAmplifiers of Channels B and A. These pins must be connected to a DC supply through impedance matching inductors, ortransformer center-taps. Typical DC current consumption is 50.5 mA into each pin.

IFBB, IFBA (Pins 11, 20): Bias Adjust Pins for the IF Amplifiers. These pins allow independent adjustment of the internal IF buffer currents for channels $B$ and $A$, respectively. The typical DC voltage on these pins is 2.2 V . If not used, these pins must be DC isolated from ground and $V_{C C}$.
$V_{\text {CCB }}$ and $V_{\text {CCA }}$ (Pins 12, 19): Power Supply Pins for the LO Buffers and Bias Circuits. These pins must be connected to a regulated 3.3 V supply with bypass capacitors located close to the pins. Typical current consumption is 99.5 mA per pin.

ENB, ENA (Pins 14, 17): Enable Pins. These pins allow Channels B and A, respectively, to be independently enabled. An applied voltage of greater than 2.5 V activates the associated channel while a voltage of less than 0.3 V disables the channel. Typical input current is less than $10 \mu \mathrm{~A}$. These pins must not be allowed to float.

LO (Pin 16): Single-Ended Local Oscillator Input. This pin is internally connected to the primary side of the LO input transformer and has a low DC resistance to ground. Series DC-blocking capacitors should be used to avoid damage to the integrated transformer when DC voltage present at LO input. The LO input is internally matched to $50 \Omega$ for all states of ENA and ENB.
$I_{\text {SEL }}$ (Pin 18): Low Power SelectPin. When this pin is pulled low (<0.3V), both mixer channels are biased at the normal current level for best RF performance. When greater than 2.5 V is applied, both channels operate at reduced current, which provides reasonable performance at lower power consumption. This pin must not be allowed to float.

Figure 1. Standard Downmixer Test Circuit Schematic (190MHz IF)

## APPLICATIONS INFORMATION

## Introduction

The LTC5592 consists of two identical mixer channels driven by a common LO input signal. Each high linearity mixer consists of a passive double-balanced mixer core, IF buffer amplifier, LO buffer amplifier and bias/enable circuits. See the Pin Functions and Block Diagram sections for a description of each pin. Each of the mixers can be shutdown independently to reduce power consumption and low current mode can be selected that allows a trade-off between performance and powerconsumption. The RFand LO inputs are single-ended and are internally matched to $50 \Omega$. Low side or high side LO injection can be used. The IF outputs are differential. The evaluation circuit, shown in Figure 1, utilizes bandpass IF output matching and an IF transformer to realize a $50 \Omega$ single-ended IF output. The evaluation board layout is shown in Figure 2.

Figure 2. Evaluation Board Layout (DC1710A)

## RF Inputs

The RF inputs of channels $A$ and $B$ are identical. The RF input of channel $A$, shown in Figure 3, is connected to the primary winding of an integrated transformer. $A 50 \Omega$ match is realized when a series external capacitor, C1A, is connected to the RF input. C1A is also needed for DC blocking if the source has DC voltage present, since the primary side of the RF transformer is internally DC-grounded. The DC resistance of the primary is approximately $3.9 \Omega$.

The secondary winding of the RF transformer is internally connected to the channel A passive mixer core. The center-tap of the transformer secondary is connected to Pin 2 (CTA) to allow the connection of bypass capacitor, C8A. The value of C8A can be adjusted to improve channel isolation at specific RF frequencies with minor impact to conversion gain, linearity and noise performance. When used, it should be located within 2 mm of Pin 2 for proper high frequency decoupling. The nominal DC voltage on the CTA pin is 1.2 V .

For the RF inputs to be properly matched, the appropriate LO signal must be applied to the LO input. A broadband input match is realized with $\mathrm{C} 1 \mathrm{~A}=22 \mathrm{pF}$. The measured input return loss is shown in Figure 4 for LO frequencies of $1.7 \mathrm{GHz}, 2.16 \mathrm{GHz}$ and 2.5 GHz . These LO frequencies correspond to lower, middle and upper values in the LO range. As shown in Figure 4, the RF input impedance is dependent on LO frequency, although a single value of C1A is adequate to cover the 1.7 GHz to 2.5 GHz RF band.

Figure 3. Channel A RF Input Schematic

Figure 4. RF Port Return Loss

## APPLICATIONS InFORMATION

The RF input impedance and input reflection coefficient, versus RF frequency, are listed in Table 1. The reference plane for this data is Pin 1 of the IC, with no external matching, and the LO is driven at 2.16 GHz .

Table 1. RF Input Impedance and S11

Figure 5. LO Input Schematic

## LO Input

The LO input, shown in Figure 5, is connected to the primary winding of an integrated transformer. A $50 \Omega$ impedance match is realized at the LO port by adding an external series capacitor, C 2 . This capacitor is also needed for DC blocking if the LO source has DC voltage present, since the primary side of the LO transformer is DC-grounded internally. The DC resistance of the primary is approximately $1.8 \Omega$.

The secondary of the transformer drives a pair of high speed limiting differential amplifiers for channels $A$ and $B$. The LTC5592's LO amplifiers are optimized for the 1.7 GHz to 2.5 GHz LO frequency range; however, LO frequencies outside this frequency range may be used with degraded performance.
The $L 0$ port is always $50 \Omega$ matched when $V_{C C}$ is applied, even when one or both of the channels is disabled. This helps to reduce frequency pulling of the LO source when the mixer is switched between different operating states. Figure 6 illustrates the LO port return loss for the different operating modes.

5592 F06
Figure 6. LO Input Return Loss
The nominal LO input level is 0 dBm , though the limiting amplifiers will deliver excellent performance over $a \pm 6 \mathrm{dBm}$ input power range. Table 2 lists the LO input impedance and input reflection coefficient versus frequency.

Table 2. LO Input Impedance vs Frequency
(at Pin 16, No External Matching, ENA = ENB = High)

## APPLICATIONS INFORMATION

## IF Outputs

The IF amplifiers in channels $A$ and $B$ are identical. The IF amplifier for channel A, shown in Figure 7, has differential open collector outputs (IFA+ and IFA ${ }^{-}$), a DC ground return pin (IFGNDA), and a pin for adjusting the internal bias (IFBA). The IF outputs must be biased at the supply voltage ( $V_{\text {CCIFA }}$ ), which is applied through matching inductors L1A and L2A. Alternatively, the IF outputs can be biased through the center tap of a transformer (T1A). The common node of L1A and L2A can be connected to the center tap of the transformer. Each IF output pin draws approximately 50.5 mA of DC supply current ( 101 mA total). An external load resistor, R2A, can be used to improve impedance matching if desired.
IFGNDA (Pin 23) must be grounded or the amplifier will not draw DC current. Inductor L3A may improve LO-IF and RF-IF leakage performance in some applications, but is otherwise not necessary. Inductors should have small resistance for DC. High DC resistance in L3A will reduce the IF amplifier supply current, which will degrade RF performance.

Figure 7. IF Amplifier Schematic with Bandpass Match

For optimum single-ended performance, the differential IF output must be combined through an external IF transformer or a discrete IF balun circuit. The evaluation board (see Figures 1 and 2) uses a 4:1 IF transformer for impedance transformation and differential to single-ended conversion. It is also possible to eliminate the IF transformer and drive differential filters or amplifiers directly.

The IF output impedance can be modeled as $379 \Omega$ in parallel with $2.2 p$. The equivalent small-signal model, including bondwire inductance, is shown in Figure 8. Frequency-dependent differential IF output impedance is listed in Table 3. This data is referenced to the package pins (with no external components) and includes the effects of IC and package parasitics.

Figure 8. IF Output Small-Signal Model

## Bandpass IF Matching

The bandpass IF matching configuration, shown in Figures 1 and 7 , is best suited for IF frequencies in the 90 MHz to 500 MHz range. Resistor R2A may be used to reduce the IF output resistance for greater bandwidth and inductors L1A and L2A resonate with the internal IF output capacitance at the desired IF frequency. The value of L1A, L2A can be estimated as follows:

$$
L 1 A=L 2 A=\frac{1}{\left[\left(2 \pi f_{I F}\right)^{2} \cdot 2 \cdot C_{\mid F}\right]}
$$

where $\mathrm{C}_{\mathrm{IF}}$ is the internal IF capacitance (listed in Table 3).

## APPLICATIONS InFORMATION

Values of L1A and L2A are tabulated in Figure 1 for various IF frequencies. The measured IF output return loss for bandpass IF matching is plotted in Figure 9.

Table 3. IF Output Impedance vs Frequency

| FREQUENCY (MHz) | DIFFERENTIAL OUTPUT <br> IMPEDANCE $\left(\mathbf{R}_{\text {IF }} \\| \mathbf{X}_{\text {IF }}\left(\mathbf{C}_{\text {IF }}\right)\right)$ |
| :---: | :---: |

| 450 | $360 \\|-\mathrm{j} 177(2.0 \mathrm{pF})$ |

5592 Fo9
Figure 9. IF Output Return Loss with Bandpass Matching

## Lowpass IF Matching

For IF frequencies below 90MHz, the inductance values become unreasonably high and the lowpass topology shown in Figure 10 is preferred. This topology also can provide improved RF to IF and LO to IF isolation. VCCIFA is supplied through the center tap of the 4:1 transformer. A lowpass impedance transformation is realized by shunt elements R2A and C9A (in parallel with the internal RIF and CIF), and series inductors L1A and L2A. Resistor R2A is used to reduce the IF output resistance for greater bandwidth, or it can be omitted for the highest conversion gain. The final impedance transformation to $50 \Omega$ is realized by transformer T1A. The measured return loss is shown in Figure 11 for different values of inductance (C9A = open). The case with 82nH inductors and a 1 k load resistor (R2A) is also shown. The LTC5592 demo

Figure 10. IF Output with Lowpass Matching

Figure 11. IF Output Return Loss with Lowpass Matching
board (see Figure 2) has been laid out to accommodate this matching topology with only minor modifications.

## IF Amplifier Bias

The IF amplifier delivers excellent performance with $V_{\text {CCIF }}$ $=3.3 \mathrm{~V}$, which allows a single supply to be used for $\mathrm{V}_{C C}$ and $V_{\text {CCIF }}$. At $V_{\text {CCIF }}=3.3 \mathrm{~V}$, the RF input P1dB of the mixer is limited by the output voltage swing. For higher P1dB, in this case, resistor R2A (Figure 7) can be used to reduce the output impedance and thus the voltage swing, thus improving P1dB. The trade-off for improved P1dB will be lower conversion gain.
With $V_{\text {CCIF }}$ increased to 5 V the P 1 dB increases by over 3dB, at the expense of higher power consumption. Mixer P1dB performance at 1950MHz and 2350MHz is tabulated in Table 4 for $\mathrm{V}_{\text {CIIF }}$ values of 3.3 V and 5 V . For the highest conversion gain, high-Q wire-wound chip inductors are recommended for L1A and L2A. Low cost multilayer chip inductors may be substituted, with a slight reduction in conversion gain.

The IFBA pin (Pin 20) is available for reducing the DC current consumption of the IF amplifier, at the expense of IIP3. The nominal DC voltage at Pin 20 is 2.1 V , and this pin should be left open-circuited for optimum performance. The internal bias circuit produces a 4 mA reference for the IF amplifier, which causes the amplifier to draw approximately 101 mA . If resistor R1A is connected to Pin 20 as shown in Figure 7, a portion of the reference current can be shunted to ground, resulting in reduced IF amplifier current. For example, R1A $=1 \mathrm{k}$ will shunt away 1.5 mA from Pin 20 and the IF amplifier current will be reduced by $25 \%$ to approximately 75.5 mA . Table 5 summarizes RF performance versus IF amplifier current.

## Low Power Mode

Both mixer channels can be set to low power mode using the I ${ }_{\text {sEL }}$ pin. This allows flexibility to select a reduced current mode of operation when lower RF performance is acceptable, reducing power consumption by $37 \%$. Figure 12 shows a simplified schematic of the I ISEL pin interface. When $I_{\text {SEL }}$ is set low ( $<0.3 \mathrm{~V}$ ), both channels operate at nominal DC current. When ISEL is set high (>2.5V), the DC current in both channels is reduced, thus reducing power consumption. The performance in low power mode and normal power mode are compared in Table 6.

Figure 12. ISEL Interface Schematic

## APPLICATIONS InFORMATION

Enable Interface
Figure 13 shows a simplified schematic of the ENA pin interface (ENB is identical). To enable channel A, the ENA voltage must be greater than 2.5 V . If the enable function is not required, the enable pin can be connected directly to $\mathrm{V}_{\mathrm{CC}}$. The voltage at the enable pin should never exceed the power supply voltage $\left(\mathrm{V}_{\mathrm{CC}}\right)$ by more than 0.3 V . If this should occur, the supply current could be sourced through the ESD diode, potentially damaging the IC.

Figure 13. ENA Interface Schematic
The Enable pins must be pulled high or low. If left floating, the on/off state of the IC will be indeterminate. If a three-state condition can exist at the enable pins, then a pull-up or pull-down resistor must be used.

## Supply Voltage Ramping

Fast ramping of the supply voltage can cause a current glitch in the internal ESD protection circuits. Depending on the supply inductance, this could result in a supply voltage transient that exceeds the maximum rating. A supply voltage ramp time of greater than 1 ms is recommended.

## Spurious Output Levels

Mixer spurious output levels versus harmonics of the RF and LO are tabulated in Tables 7 and 8 for frequencies up to 10 GHz . The spur levels were measured on a standard evalution board using the test circuit shown in Figure 1. The spur frequencies can be calculated using the following equation:

$$
f_{S P U R}=\left(M \bullet f_{R F}\right)-\left(N \bullet f_{L O}\right)
$$

Table 7. IF Output Spur Levels (dBc), High Side LO

PACKAGE DESCRIPTION
Please refer to http://www.linear.com/designtools/packaging/ for the most recent package drawings.

UH Package
24-Lead Plastic QFN ( $5 \mathrm{~mm} \times 5 \mathrm{~mm}$ )
(Reference LTC DWG \# 05-08-1747 Rev A)

RECOMMENDED SOLDER PAD LAYOUT APPLY SOLDER MASK TO AREAS THAT ARE NOT SOLDERED

NOTE:

1. DRAWING IS NOT A JEDEC PACKAGE OUTLINE
2. DRAWING NOT TO SCALE
3. ALL DIMENSIONS ARE IN MILLIMETERS
4. DIMENSIONS OF EXPOSED PAD ON BOTTOM OF PACKAGE DO NOT INCLUDE

MOLD FLASH. MOLD FLASH, IF PRESENT, SHALL NOT EXCEED 0.20 mm ON ANY SIDE
5. EXPOSED PAD SHALL BE SOLDER PLATED
6. SHADED AREA IS ONLY A REFERENCE FOR PIN 1 LOCATION ON THE TOP AND BOTTOM OF PACKAGE
