512M Bit (32M x16) Synch Burst, Multi Bank SLC NOR Flash Memory

1.0 FEATURES

- Single Voltage, 1.7V to 1.95V for Read and Write operations
- Organization
 - 33,554,432 x 16 bit (Word Mode Only)
- Read While Program/Erase Operation
- Multiple Bank Architecture
 - 16 Banks (32Mb Partition)
- OTP Block : Extra 512-Word block
- Read Access Time (@ CL=30pF)
 - Asynchronous Random Access Time : 100ns
 - Synchronous Random Access Time :95ns
 - Burst Access Time :
 - 11ns(66MHz) / 9ns(83MHz) / 7ns (108MHz) / 6ns (133MHz)
- Page Mode Operation
 - 16Words Page access allows fast asynchronous read
 - Page Read Access Time :
 - 18ns(66/83MHz) / 15ns(108/133MHz)
- Burst Length :
 - Continuous Linear Burst
 - Linear Burst : 8-word & 16-word with Wrap
- Block Architecture
 - Uniform block part (K8A(10/11/12/13)15EZC) :
 - Five hundred twelve 64Kword blocks
 - Boot block part (K8A(10/11/12/13)15ET(B)C) :
 - Four 16Kword blocks and five hundred eleven 64Kword blocks (Bank 0 contains four 16 Kword blocks and thirty-one 64Kword blocks, Bank 1 ~ Bank 15 contain four hundred eighty 64Kword blocks)
- Reduce program time using the VPP
- Support 512-word Buffer Program
- Power Consumption (Typical value, CL=30pF)
 - Synchronous Read Current : 35mA
 - Program/Erase Current : 25mA
 - Read While Program/Erase Current : 45mA
 - Standby Mode/Auto Sleep Mode : 30uA
- Block Protection/Unprotection
 - Using the software command sequence
 - Last two boot blocks are protected by $\overline{WP}=V_{IL}$ (Boot block part : K8A(10/11/12/13)15ET(B)C)
 - Last one block (BA511) is protected by $\overline{WP}=V_{IL}$ (Uniform block part : K8A(10/11/12/13)15EZC)
 - All blocks are protected by $V_{PP}=V_{IL}$
- Handshaking Feature
 - Provides host system with minimum latency by monitoring RDY
- Erase Suspend/Resume
- Program Suspend/Resume
- Unlock Bypass Program/Erase
- Hardware Reset (RESET)
- Deep Power Down Mode
- Data Polling and Toggle Bits
 - Provides a software method of detecting the status of program or erase completion
- Endurance
 - 100K Program/Erase Cycles Minimum
- Extended Temperature : -25°C ~ 85°C
- Support Common Flash Memory Interface
- Output Driver Control by Configuration Register
- Low Vcc Write Inhibit
- Package : TBD

2.0 GENERAL DESCRIPTION

The K8A(10/11/12/13)15E featuring single 1.8V power supply is a 512Mbit Muxed Burst Multi Bank Flash Memory organized as 32Mx16. The memory architecture of the device is designed to divide its memory arrays into 512blocks(Uniform block part)/515blocks(Boot block part) with independent hardware protection. This block architecture provides highly flexible erase and program capability. The K8A(10/11/12/13)15E NOR Flash consists of sixteen banks. This device is capable of reading data from one bank while programming or erasing in the other bank. Regarding read access time, the K8A10/1215E provides an 11ns burst access time and an 95ns initial access time at 66MHz. At 83MHz, the K8A10/1215E provides an 9ns burst access time and an 95ns initial access time. At 108MHz, the K8A11/1315E provides an 7ns burst access time and an 95ns initial access time. At 133MHz, the K8A11/1315E provides an 6ns burst access time and an 95ns initial access time. The device performs a program operation in units of 16 bits (Word) and erases in units of a block. Single or multiple blocks can be erased. The block erase operation is completed within typically 0.6sec. The device requires 25mA as program/erase current in the extended temperature ranges.

The K8A(10/11/12/13)15E NOR Flash Memory is created by using Samsung's advanced CMOS process technology.

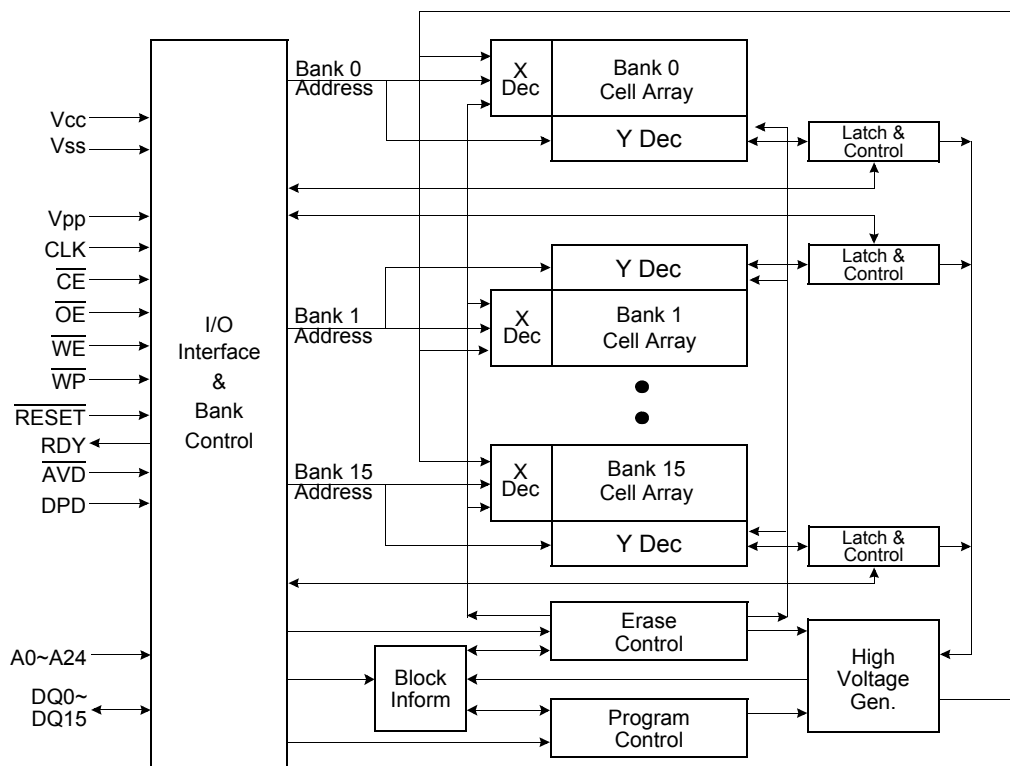

3.0 PIN DESCRIPTION

| Pin Name | Pin Function |
|--------------------|---------------------------------|
| A0 - A24 | Address Inputs |
| DQ0 - DQ15 | Data input/output |
| \overline{CE} | Chip Enable |
| \overline{OE} | Output Enable |
| \overline{RESET} | Hardware Reset Pin |
| VPP | Accelerates Programming |
| \overline{WE} | Write Enable |
| \overline{WP} | Hardware Write Protection Input |
| CLK | Clock |
| RDY | Ready Output |
| \overline{AVD} | Address Valid Input |
| DPD | Deep Power Down |
| Vcc | Power Supply |
| Vss | Ground |

7.0 PRODUCT INTRODUCTION

The K8A(10/11/12/13)15E is an 512Mbit (536,870,912 bits) NOR-type Burst Flash memory. The device features 1.8V single voltage power supply operating within the range of 1.7V to 1.95V. The device is programmed by using the Channel Hot Electron (CHE) injection mechanism which is used to program EPROMs. The device is erased electrically by using Fowler-Nordheim tunneling mechanism. To provide highly flexible erase and program capability, the device adapts a block memory architecture that divides its memory array into 512 blocks (64-Kword x 512 blocks, Uniform block part) / 515 blocks (16-Kword x 4 + 64-Kword x 511, Boot block part). Programming is done in units of 16 bits (Word). All bits of data in one or multiple blocks can be erased when the device executes the erase operation. To prevent the device from accidental erasing or over-writing the programmed data, 512 / 515 memory blocks can be hardware protected. Regarding read access time, at 66MHz, the K8A10/1215E provides a burst access of 11ns with initial access times of 95ns at 30pF. At 83MHz, the K8A10/1215E provides a burst access of 9ns with initial access times of 95ns at 30pF. At 108MHz, the K8A11/1315E provides a burst access of 7ns with initial access times of 95ns at 30pF. At 133MHz, the K8A11/1315E provides a burst access of 6ns with initial access times of 95ns at 30pF. The command set of K8A(10/11/12/13)15E is compatible with standard Flash devices. The device uses Chip Enable (\overline{CE}), Write Enable (\overline{WE}), Address Valid(\overline{AVD}) and Output Enable (\overline{OE}) to control asynchronous read and write operation. For burst operations, the device additionally requires Ready (RDY) and Clock (CLK). Device operations are executed by selective command codes. The command codes to be combined with addresses and data are sequentially written to the command registers using microprocessor write timing. The command codes serve as inputs to an internal state machine which controls the program/erase circuitry. Register contents also internally latch addresses and data necessary to execute the program and erase operations. The K8A(10/11/12/13)15E is implemented with Internal Program/Erase Routines to execute the program/erase operations. The Internal Program/Erase Routines are invoked by program/erase command sequences. The Internal Program Routine automatically programs and verifies data at specified addresses. The Internal Erase Routine automatically pre-programs the memory cell which is not programmed and then executes the erase operation. The K8A(10/11/12/13)15E has means to indicate the status of completion of program/erase operations. The status can be indicated via Data polling of DQ7, or the Toggle bit (DQ6). Once the operations have been completed, the device automatically resets itself to the read mode. The device requires only 35mA as burst and asynchronous mode read current and 25mA for Buffer program/erase operations.

[Table 7] Device Bus Operations

| Operation | \overline{CE} | \overline{OE} | \overline{WE} | A0-24 | DQ0-15 | \overline{RESET} | CLK | \overline{AVD} |

NOTE : L=VIL (Low), H=VIH (High), X=Don't Care.

8.0 COMMAND DEFINITIONS

The K8A(10/11/12/13)15E operates by selecting and executing its operational modes. Each operational mode has its own command set. In order to select a certain mode, a proper command with specific address and data sequences must be written into the command register. Writing incorrect information which include address and data or writing an improper command will reset the device to the read mode. The defined valid register command sequences are stated in Table 8.

[Table 8] Command Sequences

| Command Definitions | | Cycle | 1st Cycle | 2nd Cycle | 3rd Cycle | 4th Cycle | 5th Cycle | 6th Cycle |
|---|------|-------|-----------|-----------|-----------|-----------|-----------|-----------|

| Exit OTP Block Region | Add | 4 | 555H | 2AAH | 555H | XXX | | |
| | Data | | AAH | 55H | 75H | 00H | | |

NOTE :

- 1) RA : Read Address, PA : Program Address, RD : Read Data, PD : Program Data, BA : Block Address (A24 ~ A14), DA : Bank Address (A24 ~ A21)
ABP : Address of the block to be protected or unprotected, CR : Configuration Register Setting
WBL : Write Buffer Location, WC : Word Count
- 2) The 4th cycle data of autoselect mode and RD are output data. The others are input data.
- 3) Data bits DQ15~DQ8 are don't care in command sequences, except for RD, PD and Device ID.
- 4) Unless otherwise noted, address bits A24~A11 are don't cares.
- 5) The reset command is required to return to read mode.
If a bank entered the autoselect mode during the erase suspend mode, writing the reset command returns that bank to the erase suspend mode.
If a bank entered the autoselect mode during the program suspend mode, writing the reset command returns that bank to the program suspend mode.
If DQ5 goes high during the program or erase operation, writing the reset command returns that bank to read mode or erase suspend mode if that bank was in erase suspend mode.
- 6) The 3rd and 4th cycle bank address of autoselect mode must be same.
Device ID Data : "3013H" for Top Boot Block Device, "3014H" for Bottom Boot Block Device, "3015H" for Uniform Block Device
- 7) Normal Block Protection Verify : 00H for an unprotected block and 01H for a protected block.
OTP Block Protect verify (with OTP Block Address after Entering OTP Block) : 00H for unlocked, and 01H for locked.
- 8) 0H for handshaking, 1H for non-handshaking
- 9) The unlock bypass command sequence is required prior to this command sequence.
- 10) The system may read and program in non-erasing blocks when in the erase suspend mode.
The system may enter the autoselect mode when in the erase suspend mode.
The erase suspend command is valid only during a block erase operation, and requires the bank address.
- 11) The erase/program resume command is valid only during the erase/program suspend mode, and requires the bank address.
- 12) This mode is used only to enable Data Read by suspending the Program operation.
- 13) Set ABP(Address of the block to be protected or unprotected) as either A6 = VIH, A1 = VIH and A0 = VIL for unprotected or A6 = VIL, A1 = VIH and A0 = VIL for protected.
- 14) Command is valid when the device is in Read mode or Autoselect mode.
- 15) For Buffer Program, Firstly Enter "Write to Buffer" Command sequence and then Enter Block Address and Word Count which is the number of word data will be programmed. Word Count is smaller than the number of data wanted to program by one, Example if 15 words are wanted to program then WC (Word Count) is 14. After Entering Command, Enter PA/PD's (Program Addresses/ Program Data). Finally Enter "Program buffer to Flash" Command sequence, This starts a buffer program operation. This Device supports 512-word Buffer Program.
There is some caution points.
- The number of PA/PD's which are entered must be same to WC+1
- PA's which are entered must be same A24~A9 address bits because Buffer Address is A24~A9 address and decided by PA entered firstly.
- If PA which are entered isn't same Buffer Address, then PA/PD which is entered may be ignored and this buffer programming operation is aborted.
To return to normal operation, hardware reset or "Write to Buffer Abort Reset" command is issued.
- Overwrite for program buffer is also prohibited.
- 16) Command sequence resets device for next command after aborted write-to-buffer operation.
- 17) See "Set Burst Mode Configuration Register" for details.
- 18) On the third cycle, the data should be "C0h", address bits A10-A0 should be 101_0101_0101b, and address bits A21-A11 set the code to be latched.
- 19) On the third cycle, the data should be "C5h", address bits A10-A0 should be 101_0101_0101b, and address bits A21-A11 set the code to be latched.
- 20) After software reset and write to buffer abort reset command, min. 5us recovery time is needed for normal read mode.

9.0 DEVICE OPERATION

The device has inputs/outputs that accept both address and data information. To write a command or command sequence (which includes programming data to the device and erasing blocks of memory), the system must drive CLK, WE and CE to VIL and OE to VIH when writing commands or data. The device provides the unlock bypass mode to save its program time for program operation. Unlike the standard program command sequence which is comprised of four bus cycles, only two program cycles are required to program a word in the unlock bypass mode. One block, multiple blocks, or the entire device can be erased. Table 17 indicates the address space that each block occupies. The device's address space is divided into sixteen banks. A "bank address" is the address bits required to uniquely select a bank. Similarly, a "block address" is the address bits required to uniquely select a block. ICC2 in the DC Characteristics table represents the active current specification for the write mode. The AC Characteristics section contains timing specification tables and timing diagrams for write operations.

9.1 Read Mode

The device automatically enters to asynchronous read mode after device power-up. For synchronous read, the device needs to be set mode register prior to read operation. After completing an Internal Program/Erase Routine, each bank is ready to read array data. The reset command is required to return a bank to the read(or erase-suspend-read)mode if DQ5 goes high during an active program/erase operation, or if the bank is in the autoselect mode.

(1) K8A1015ET(B)(Z)C : 66/83Mhz with the Sync MRS option (Extended Configuration Register)

(2) K8A1115ET(B)(Z)C : 108/133Mhz with the Sync MRS option (Extended Configuration Register)

The synchronous(burst) mode will automatically start on the rising edge of the CLK input while \overline{AVD} is held low after Extended Mode Register Setting to A13=0, A12=1. If several CLKs exist in \overline{AVD} low, the last rising edge is valid CLK.

(3) K8A1215ET(B)(Z)C : 66/83Mhz with no option

(4) K8A1315ET(B)(Z)C : 108/133Mhz with no option

The synchronous(burst) mode will automatically start on the rising edge of the CLK input while \overline{AVD} is held low. If several CLKs exist in \overline{AVD} low, the last rising edge is valid CLK.

9.1.1. Asynchronous Read Mode

For the asynchronous read mode a valid address should be asserted on A0-A24, while driving \overline{AVD} and CE to VIL. WE should remain at VIH. The data will appear on DQ0-DQ15. Since the memory array is divided into sixteen banks, each bank remains enabled for read access until the command register contents are altered.

Address access time (tAA) is equal to the delay from valid addresses to valid output data. The chip enable access time(tCE) is the delay from the falling edge of CE to valid data at the outputs. The output enable access time(tOE) is the delay from the falling edge of OE to valid data at the output. To prevent the memory content from spurious altering during power transition, the initial state machine is set for reading array data upon device power-up, or after a hardware reset.

9.1.1.1 . Asynchronous Page Read Mode

16-Words Page mode is supported for fast asynchronous read. After address access time(tAA), sixteen data words are loaded into an internal page buffer. A0~A3 bits determine which page word is output during a read operation. A4~A24 and \overline{AVD} must be stable throughout the page read access. Figure 11 shows the Asynchronous Page Read Mode timing.

9.1.2. Synchronous (Burst) Read Mode

The device is capable of continuous linear burst operation and linear burst operation of a preset length. For the burst mode, the system should determine how many clock cycles are desired for the initial word(tIAA) of each burst access and what mode of burst operation is desired using "Burst Mode Configuration Register" command sequences. See "Set Burst Mode Configuration" for further details. The status data also can be read during burst read mode by using \overline{AVD} signal with a bank address which is programming or erasing. To initiate the synchronous read again, a new address and \overline{AVD} pulse is needed after the host has completed status reads or the device has completed the program or erase operation.

9.1.2.1 . Continuous Linear Burst Read

(1) K8A1015ET(B)(Z)C : 66/83Mhz with the Sync MRS option (Extended Configuration Register)

(2) K8A1115ET(B)(Z)C : 108/133Mhz with the Sync MRS option (Extended Configuration Register)

The synchronous(burst) mode will automatically start on the rising edge of the CLK input while \overline{AVD} is held low after Extended Mode Register Setting to A13=0, A12=1. If several CLKs exist in \overline{AVD} low, the last rising edge is valid CLK.

(3) K8A1215ET(B)(Z)C : 66/83Mhz with no option

(4) K8A1315ET(B)(Z)C : 108/133Mhz with no option

The synchronous(burst) mode will automatically start on the rising edge of the CLK input while \overline{AVD} is held low. If several CLKs exist in \overline{AVD} low, the last rising edge is valid CLK.

The initial word is output tIAA after the rising edge of the last CLK cycle. Subsequent words are output tBA after the rising edge of each successive clock cycle, which automatically increase the internal address counter. Note that the device has internal address boundary that occurs every 16 words. When the device is crossing the first word boundary, additional clock cycles are needed before data appears for the next address. The number of additional clock cycle can vary from zero to thirteen cycles, and the exact number of additional clock cycle depends on the starting address of burst read. The RDY output indicates this condition to the system by pulsing low. The device will continue to output sequential burst data, wrapping around to address 0000000h after it reaches the highest addressable memory location until the system asserts CE high, RESET low or \overline{AVD} low in conjunction with a new address.(Refer to Table 7.) The reset command does not terminate the burst read operation. When it accesses the bank is programming or erasing, continuous burst read mode will output status data. And status data will be sustained until the system asserts CE high or RESET low or \overline{AVD} low in conjunction with a new address. Note that at least 10ns is needed to start next burst read operation from terminating previous burst read operation in the case of asserting CE high.

8-, 16-Word Linear Burst Read

As well as the Continuous Linear Burst Mode, there are two(8 & 16 word) linear wrap, in which a fixed number of words are read from consecutive addresses. In these modes, the addresses for burst read are determined by the group within which the starting address falls. The groups are sized according to the number of words read in a single burst sequence for a given mode. (Refer to Table 9)

[Table 9] Burst Address Groups (Wrap mode)

| Burst Mode | Group Size | Group Address Ranges |
|------------|------------|----------------------------|
| 8 word | 8 words | 0-7h, 8-Fh, 10-17h, |
| 16 word | 16 words | 0-Fh, 10-1Fh, 20-2Fh, |

As an example: In wrap mode case, if the starting address in the 8-word mode is 2h, the address range to be read would be 0-7h, and the wrap burst sequence would be 2-3-4-5-6-7-0-1h. The burst sequence begins with the starting address written to the device, but wraps back to the first address in the selected group. In a similar manner, 16-word wrap mode begins its burst sequence on the starting address written to the device, and then wrap back to the first address in the selected address group.

9.2 Programmable Wait State

The programmable wait state feature indicates to the device the number of additional clock cycles that must elapse after \overline{AVD} is driven from low to high for burst read mode. Upon power up, the number of total initial access cycles defaults to fourteen.

9.3 Handshaking

The handshaking feature allows the host system to simply monitor the RDY signal from the device to determine when the initial word of burst data is ready to be read. To set the number of initial cycle for optimal burst mode, the host should use the programmable wait state configuration. (See "Set Burst Mode Configuration Register" for details.) The rising edge of RDY after OE goes low indicates the initial word of valid burst data. (RDY can be low active by Extended configuration register A11 setting : RDY low indicates data valid) Using the autoselect command sequence, the handshaking feature will be verified in the device.

9.4 Set Burst Mode Configuration Register

The device uses a configuration register to set the various burst parameters : the number of initial cycles for burst and burst read mode. The burst mode configuration register must be set before the device enters burst mode. The burst mode configuration register is loaded with a three-cycle command sequences. On the third cycle, the data should be C0h, address bits A10-A0 should be 101_0101_0101b, and address bits A21-A11 set the code to be latched. The device returns to default setting after power up or hardware reset.

9.4.1. Programmable Wait State Configuration

This feature informs the device the number of clock cycles that must elapse after \overline{AVD} is driven from low to high before data will be available. This value is determined by the input frequency of the device. Address bits A14-A11 determine the setting. (See Configuration Register Table 10.) The Programmable wait state setting instructs the device to set a particular number of clock cycles for the initial access in burst mode. Note that hardware reset will revert the wait state to the default setting, that is 14 initial cycles.

9.4.2. Burst Read Mode Setting

The device supports three different burst read modes : continuous linear mode, 8 and 16 word linear burst modes with wrap.

9.4.3. RDY Configuration

By default, the RDY pin will be high whenever there is valid data on the output. (RDY can be low active by configuration register A11 setting : RDY low indicates data valid) The device can be set so that RDY goes active one data cycle before active data. Address bit A18 determines this setting. The RDY pin behaves same way in word boundary crossing case.

[Table 10] Burst Mode Configuration Register Table

| Address Bit | Function | Settings (Binary) |
|---|-------------------------|---|
| A21 | Output Driver Control | 000 = setting 0 |
| A20 | | 001 = setting 1 |
| A19 | | 010 = setting 2 (Reserve) |
| | | 011 = setting 3 (Reserve) |
| A18 | RDY Active | 100 = setting 4 (default) |
| | | 101 = setting 5 (Reserve) |
| A17 | Burst Read Mode | 110 = setting 6 (Reserve) |
| | | 111 = setting 7 |
| A16 | | 0 = RDY active with data (default) |
| A15 | | 1 = RDY active one clock cycle before data |
| A14 | Programmable Wait State | 000 = Continuous (default) |
| A13 | | 001 = 8-word linear with wrap |
| A12 | | 010 = 16-word linear with wrap |
| | | 011 ~ 111 = Reserve |
| A11 | Programmable Wait State | 0000 = Data is valid on the 4th active CLK edge after \overline{AVD} transition to VIH |
| | | 0001 = Data is valid on the 5th active CLK edge after \overline{AVD} transition to VIH (40Mhz*) |
| | | 0010 = Data is valid on the 6th active CLK edge after \overline{AVD} transition to VIH (50/54Mhz*) |
| | | 0011 = Data is valid on the 7th active CLK edge after \overline{AVD} transition to VIH (60/66Mhz*) |
| | | 0100 = Data is valid on the 8th active CLK edge after \overline{AVD} transition to VIH (70Mhz*) |
| | | 0101 = Data is valid on the 9th active CLK edge after \overline{AVD} transition to VIH (80/83Mhz*) |
| | | 0110 = Data is valid on the 10th active CLK edge after \overline{AVD} transition to VIH (90/100Mhz*) |
| | | 0111 = Data is valid on the 11th active CLK edge after \overline{AVD} transition to VIH (108/110Mhz*) |
| | | 1000 = Data is valid on the 12th active CLK edge after \overline{AVD} transition to VIH (120Mhz*) |
| | | 1001 = Data is valid on the 13th active CLK edge after \overline{AVD} transition to VIH (133Mhz*,default) |
| | | 1010 = Data is valid on the 14th active CLK edge after \overline{AVD} transition to VIH |
| 1011 = Data is valid on the 15th active CLK edge after \overline{AVD} transition to VIH | | |
| 1100 ~ 1111 = Reserve | | |

NOTE :

Initial wait state should be set according to it's clock frequency. Table 10 recommend the program wait state for each clock frequencies.

Not 100% tested

[Table 11] Extended Configuration Register Table

| Address Bit | Function | Settings (Binary) |
|-------------|--------------|---|
| A13 | Read Mode | 00 = Asynchronous Read Mode(default) |
| A12 | | 01 = Synchronous Burst Read Mode |
| A11 | RDY Polarity | 10 ~ 11 = Reserve |
| | | 0 = RDY signal is active high (default) |
| | | 1 = RDY signal is active low |

NOTE :

Default mode is asynchronous read mode. (A13=0, A12=0) In this mode device is still in asynchronous read even if it is in CLK rising while \overline{AVD} low condition.

To use synchronous read mode, user should set Extended Configuration Register (A13=0, A12=1). In this mode both of asynchronous and synchronous read mode is available.

The synchronous (burst) mode should be started on the last rising edge of the CLK input while \overline{AVD} is held low after Extended Mode Register Setting to A13=0, A12=1.

[Table 12] Burst Address Sequences

| | Start Addr. | Burst Address Sequence | | |
|------|-------------|------------------------|-----------------|--------------------|
| | | Continuous Burst | 8-word Burst | 16-word Burst |
| Wrap | 0 | 0-1-2-3-4-5-6... | 0-1-2-3-4-5-6-7 | 0-1-2-3 ... -D-E-F |
| | 1 | 1-2-3-4-5-6-7... | 1-2-3-4-5-6-7-0 | 1-2-3-4 ... -E-F-0 |
| | 2 | 2-3-4-5-6-7-8... | 2-3-4-5-6-7-0-1 | 2-3-4-5 ... -F-0-1 |
| | . | . | . | . |

9.5 Output Driver Setting

The device supports four kinds of output driver setting for matching the system characteristics. The users can tune the output driver impedance of the data and RDY outputs by address bits A21-A19. (See Configuration Register Table) Table 13 shows which output driver would be tuned and the strength according to A21-A19. Upon power-up or reset, the register will revert to the default setting.

[Table 13] Output Driver setting Table

| Address Bits | Value | Function |
|--------------|-------|---------------------------------|
| A21-A19 | 000 | Driver Multiplier : 1/3 |
| | 001 | Driver Multiplier : 1/2 |
| | 010 | Reserve |
| | 011 | Reserve |
| | 100 | Driver Multiplier : 1 (default) |
| | 101 | Reserve |
| | 110 | Reserve |
| | 111 | Driver Multiplier : 1.5 |

9.6 Autoselect Mode

By writing the autoselect command sequences to the system, the device enters the autoselect mode. This mode can be read only by asynchronous read mode. The system can then read autoselect codes from the internal register (which is separate from the memory array). Standard asynchronous read cycle timings apply in this mode. The device offers the Autoselect mode to identify manufacturer and device type by reading a binary code. In addition, this mode allows the host system to verify the block protection or unprotection. Table 14 shows the address and data requirements. The autoselect command sequence may be written to an address within a bank that is in the read mode, erase-suspend-read mode or program-suspend-read mode. The autoselect command may not be written while the device is actively programming or erasing in the device. The autoselect command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle that contains the address and the autoselect command. Note that the block address is needed for the verification of block protection. The system may read at any address within the same bank any number of times without initiating another autoselect command sequence. And the burst read should be prohibited during Autoselect Mode. To terminate the autoselect operation, write Reset command(F0H) into the command register.

[Table 14] Autoselect Mode Description

| Description | Address | Read Data |
|-------------------------------|------------|--|
| Manufacturer ID | (DA) + 00H | ECH |
| Device ID | (DA) + 01H | 3013H (Top Boot Block), 3014H (Bottom Boot Block), 3015H (Uniform Block) |
| Block Protection/Unprotection | (BA) + 02H | 01H (protected), 00H (unprotected) |
| Handshaking | (DA) + 03H | 0H : handshaking, 1H : non-handshaking |

9.7 Standby Mode

When the CE inputs is held at $V_{CC} \pm 0.2V$, and the system is not reading or writing, the device enters Stand-by mode to minimize the power consumption. In this mode, the device outputs are placed in the high impedance state, independent of the OE input. When the device is in either of these standby modes, the device requires standard access time (tCE) for read access before it is ready to read data. If the device is deselected during erasure or programming, the device draws active current until the operation is completed. ICC5 in the DC Characteristics table represents the standby current specification.

9.8 Automatic Sleep Mode

The device features Automatic Sleep Mode to minimize the device power consumption during both asynchronous and burst mode. When addresses remain stable for $t_{AA}+60ns$, the device automatically enables this mode. The Automatic sleep mode is depends on the CE, WE and OE signal, so CE, WE and OE signals are held at any state. In a sleep mode, output data is latched and always available to the system. When OE is active, the device provides new data without wait time. Automatic sleep mode current is equal to standby mode current.

9.9 Output Disable Mode

When the OE input is at VIH, output from the device is disabled. The outputs are placed in the high impedance state.

9.10 Block Protection & Unprotection

To protect the block from accidental writes, the block protection/unprotection command sequence is used. On power up, all blocks in the device are protected. To unprotect a block, the system must write the block protection/unprotection command sequence. The first two cycles are written: addresses are don't care and data is 60h. Using the third cycle, the block address (ABP) and command (60h) is written, while specifying with addresses A6, A1 and A0 whether that block should be protected (A6 = VIL, A1 = VIH, A0 = VIL) or unprotected (A6 = VIH, A1 = VIH, A0 = VIL). After the third cycle, the system can continue to protect or unprotect additional cycles, or exit the sequence by writing F0h (reset command).

The device offers three types of data protection at the block level:

- The block protection/unprotection command sequence disables or re-enables both program and erase operations in any block.
- When \overline{WP} is at VIL, the two outermost blocks are protected.(Boot block part : K8A(10/11/12/13)15ET(B)C)
- When \overline{WP} is at VIL, the last one block (BA511) is protected.(Uniform block part :K8A(10/11/12/13)15EZC)
- When V_{PP} is at VIL, all blocks are protected.

Note that user never float the Vpp and WP, that is, Vpp is always connected with VIH, VIL or VID and WP is VIH or VIL.

9.11 Hardware Reset

The device features a hardware method of resetting the device by the RESET input. When the RESET pin is held low(VIL) for at least a period of tRP, the device immediately terminates any operation in progress, tristates all outputs, and ignores all read/write commands for the duration of the RESET pulse. The device also resets the internal state machine to asynchronous read mode. To ensure data integrity, the interrupted operation should be reinitiated once the device is ready to accept another command sequence. The RESET pin may be tied to the system reset pin. If a system reset occurs during the Internal Program or Erase Routine, the device will be automatically reset to the asynchronous read mode; this will enable the systems microprocessor to read the boot-up firmware from the Flash memory. If RESET is asserted during a program or erase operation, the device requires a time of tREADY (during Internal Routines) before the device is ready to read data again. If RESET is asserted when a program or erase operation is not executing, the reset operation is completed within a time of tREADY (not during Internal Routines). tRH is needed to read data after RESET returns to VIH. Refer to the AC Characteristics tables for RESET parameters and to Figure 12 for the timing diagram. When RESET is at logic high, the device is in standard operation. When RESET transitions from logic-low to logic-high, the device resets all blocks to locked and defaults to the read array mode.

9.12 Software Reset

The reset command provides that the bank is reseted to read mode, erase-suspend-read mode or program-suspend-read mode. The addresses are in Don't Care state. The reset command may be written between the sequence cycles in an erase command sequence before erasing begins, or in an program command sequence before programming begins. If the device begins erasure or programming, the reset command is ignored until the operation is completed. If the program command sequence is written to a bank that is in the Erase Suspend mode, writing the reset command returns that bank to the erase-suspend-read mode. The reset command valid between the sequence cycles in an autoselect command sequence. In an autoselect mode, the reset command must be written to return to the read mode. If a bank entered the autoselect mode while in the Erase Suspend mode, writing the reset command returns that bank to the erase-suspend-read mode. Also, if a bank entered the autoselect mode while in the Program Suspend mode, writing the reset command returns that bank to the program-suspend-read mode. If DQ5 goes high during a program or erase operation, writing the reset command returns the banks to the read mode. (or erase-suspend-read mode if the bank was in Erase Suspend)

9.13 Program

The K8A(10/11/12/13)15E can be programmed in units of a word. Programming is writing 0's into the memory array by executing the Internal Program Routine. In order to perform the Internal Program Routine, a four-cycle command sequence is necessary. The first two cycles are unlock cycles. The third cycle is assigned for the program setup command. In the last cycle, the address of the memory location and the data to be programmed at that location are written. The device automatically generates adequate program pulses and verifies the programmed cell margin by the Internal Program Routine. During the execution of the Routine, the system is not required to provide further controls or timings. During the Internal Program Routine, commands written to the device will be ignored.

Note that a hardware reset during a program operation will cause data corruption at the corresponding location.

9.14 Accelerated Program

The device provides accelerated program operations through the Vpp input. Using this mode, faster manufacturing throughput at the factory is possible. When VID is asserted on the Vpp input, the device automatically enters the Unlock Bypass mode, temporarily unprotected any protected blocks, and uses the higher voltage on the input to reduce the time required for program operations. In accelerated program mode, the system would use a two-cycle program command sequence for only a word program. By removing VID returns the device to normal operation mode.

Note that Read While Accelerated Program (Erase) and Program suspend (Erase suspend) mode are not guaranteed.

- Program/Erase cycling must be limited below 100cycles for optimum performance.
- Ambient temperature requirements : TA = 30°C±10°C

9.15 Write Buffer Programming

Write Buffer Programming allows the system write to a maximum of 512-word in one programming operation. This results in faster effective programming time than the standard programming algorithms. The Write Buffer Programming command sequence is initiated by first writing two unlock cycles. This is followed by a third write cycle containing the Write Buffer Load command written at the block address in which programming will occur. The fourth cycle writes the block address and the number of word locations, minus one, to be programmed. For example, if the system will program 19 unique address locations, then 12h should be written to the device. This tells the device how many write buffer addresses will be loaded with data. The number of locations to program cannot exceed the size of the write buffer or the operation will abort. The fifth cycle writes the first address location and data to be programmed. The write-buffer-page is selected by address bits A24(max.) ~ A9 entered at fifth cycle. All subsequent address/ data pairs must fall within the selected write-buffer-page, so that all subsequent addresses must have the same address bit A24(max.) ~ A9 as those entered at fifth cycle. Write buffer locations may be loaded in any order.

Once the specified number of write buffer locations have been loaded, the system must then write the "Program Buffer to Flash" command at the block address. Any other command address/data combination aborts the Write Buffer Programming operation. The device then begins programming. Data polling should be used while monitoring the last address location loaded into the write buffer. DQ7, DQ6, DQ5, and DQ1 should be monitored to determine the device status during Write Buffer Programming. The write-buffer programming operation can be suspended using the standard program suspend/resume commands. Upon successful completion of the Write Buffer Programming operation, the device is ready to execute the next command.

Note also that an address location cannot be loaded more than once into the write-buffer-page.

The Write Buffer Programming Sequence can be aborted in the following ways:

- Loading a value that is greater than the buffer size(512-word) during then number of word locations to Program step.
(In case, WC > 1FFH @Table 8)
- The number of Program address/data pairs entered is different to the number of word locations initially defined with WC (@ Table 8)
- Writing a Program address to have a different write-buffer-page with selected write-buffer-page
(Address bits A24(max) ~ A9 are different)
- Writing non-exact "Program Buffer to Flash" command

The abort condition is indicated by DQ1 = 1, DQ7 = DATA (for the last address location loaded), DQ6 = toggle, and DQ5=0. A "Write-to-Buffer-Abort Reset" command sequence must be written to reset the device for the next operation. Note that the third cycle of Write-to-Buffer-Abort Reset command sequence is required when using Write-Buffer-Programming features in Unlock Bypass mode.

And from the third cycle to the last cycle of Write to Buffer command is also required when using Write-Buffer-Programming features in Unlock Bypass mode. A bit cannot be programmed from "0" back to a "1." Attempting to do so may cause the DQ7 and DQ6 status bits to indicate the operation was successful. However, a succeeding read will show that the data is still "0." Only erase operations can convert a "0" to a "1."

www.DataSheet4U.com

9.16 Accelerated Write Buffer Programming

The device provides accelerated Write Buffer Program operations through the Vpp input. Using this mode, faster manufacturing throughput at the factory is possible. When VID is asserted on the Vpp input, the device temporarily unprotects any protected blocks, and uses the higher voltage on the input to reduce the time required for program operations. In accelerated Write Buffer Program mode, the system must enter "Write to Buffer" and "Program Buffer to Flash" command sequence to be same as them of normal Write Buffer Programming. Note that the third cycle of "Write to Buffer Abort Reset" command sequence is required in an accelerated mode.

Note that Read While Accelerated Write Buffer Program and Program suspend mode are not guaranteed.

- Program/Erase cycling must be limited below 100cycles for optimum performance.
- Ambient temperature requirements : TA = 30°C±10°C

9.17 Chip Erase

To erase a chip is to write 1's into the entire memory array by executing the Internal Erase Routine. The Chip Erase requires six bus cycles to write the command sequence. The erase set-up command is written after first two "unlock" cycles. Then, there are two more write cycles prior to writing the chip erase command. The Internal Erase Routine automatically pre-programs and verifies the entire memory for an all zero data pattern prior to erasing. The automatic erase begins on the rising edge of the last WE pulse in the command sequence and terminates when DQ7 is "1". After that the device returns to the read mode.

9.18 Block Erase

To erase a block is to write 1's into the desired memory block by executing the Internal Erase Routine. The Block Erase requires six bus cycles to write the command sequence shown in Table 8. After the first two "unlock" cycles, the erase setup command (80H) is written at the third cycle. Then there are two more "unlock" cycles followed by the Block Erase command. The Internal Erase Routine automatically pre-programs and verifies the entire memory prior to erasing it. Multiple blocks can be erased sequentially by writing the sixth bus-cycle. Upon completion of the last cycle for the Block Erase, additional block address and the Block Erase command (30H) can be written to perform the Multi-Block Erase. For the Multi-Block Erase, only sixth cycle(block address and 30H) is needed.(Similarly, only second cycle is needed in unlock bypass block erase.) An 50us (typical) "time window" is required between the Block Erase command writes. The Block Erase command must be written within the 50us "time window", otherwise the Block Erase command will be ignored. The 50us "time window" is reset when the falling edge of the WE occurs within the 50us of "time window" to latch the Block Erase command. During the 50us of "time window", any command other than the Block Erase or the Erase Suspend command written to the device will reset the device to read mode. After the 50 us of "time window", the Block Erase command will initiate the Internal Erase Routine to erase the selected blocks. Any Block Erase address and command following the exceeded "time window" may or may not be accepted. No other commands will be recognized except the Erase Suspend command during Block Erase operation.

9.19 Unlock Bypass

The K8A(10/11/12/13)15E provides the unlock bypass mode to save its operation time. This mode is possible for program, block erase, chip erase, write to buffer and write to buffer abort reset operation. There are two methods to enter the unlock bypass mode. The mode is invoked by the unlock bypass command sequence or the assertion of VID on VPP pin. Unlike the standard program/erase command sequence that contains four bus cycles, the unlock bypass program/erase command sequence comprises only two bus cycles. The unlock bypass mode is engaged by issuing the unlock bypass command sequence which is comprised of three bus cycles. Writing first two unlock cycles is followed by a third cycle containing the unlock bypass command (20H). Once the device is in the unlock bypass mode, the unlock bypass program/erase command sequence is necessary. The unlock bypass program command sequence is comprised of only two bus cycles; writing the unlock bypass program command (A0H) is followed by the program address and data. This command sequence is the only valid one for programming the device in the unlock bypass mode. Also, The unlock bypass erase command sequence is comprised of two bus cycles; writing the unlock bypass block erase command(80H-30H) or writing the unlock bypass chip erase command(80H-10H). This command sequences are the only valid ones for erasing the device in the unlock bypass mode. The unlock bypass reset command sequence is the only valid command sequence to exit the unlock bypass mode. The unlock bypass reset command sequence consists of two bus cycles. The first cycle must contain the data (90H). The second cycle contains only the data (00H). Then, the device returns to the read mode.

To enter the unlock bypass mode in hardware level, the VID also can be used. By assertion VID on the VPP pin, the device enters the unlock bypass mode. Also, the all blocks are temporarily unprotected when the device using the VID for unlock bypass mode. To exit the unlock bypass mode, just remove the asserted VID from the VPP pin.(Note that user never float the Vpp, that is, Vpp is always connected with VIH, VIL or VID.).

9.20 Erase Suspend / Resume

The Erase Suspend command interrupts the Block Erase to read or program data in a block that is not being erased. Also, it is possible to protect or unprotect of the block that is not being erased in erase suspend mode. The Erase Suspend command is only valid during the Block Erase operation including the time window of 50us. The Erase Suspend command is not valid while the Chip Erase or the Internal Program Routine sequence is running. When the Erase Suspend command is written during a Block Erase operation, the device requires a maximum of 30us(recovery time) to suspend the erase operation. Therefore system must wait for 30us(recovery time) to read the data from the bank which include the block being erased. Otherwise, system can read the data immediately from a bank which don't include the block being erased without recovery time(max. 30us) after Erase Suspend command. And, after the maximum 30us recovery time, the device is available for programming data in a block that is not being erased. But, when the Erase Suspend command is written during the block erase time window (50us), the device terminates the block erase time window and suspends the erase operation in about 2us. The system may also write the autoselect command sequence when the device is in the Erase Suspend mode. When the Erase Resume command is executed, the Block Erase operation will resume. When the Erase Suspend or Erase Resume command is executed, the addresses are in the bank address which is operating in Erase Suspend or Erase Resume. While erase can be suspended and resumed multiple times, a minimum 30us is required from resume to the next suspend.

9.21 Program Suspend / Resume

The device provides the Program Suspend/Resume mode. This mode is used to enable Data Read by suspending the Program operation. The device accepts a Program Suspend command in Program mode (including Program operations performed during Erase Suspend) but other commands are ignored. After input of the Program Suspend command, 5us is needed to enter the Program Suspend Read mode. Therefore system must wait for 5us(recovery time) to read the data from the bank which include the block being programmed. Otherwise, system can read the data immediately from a bank which don't include block being programmed without recovery time (max. 5us) after Program Suspend command. Like an Erase Suspend mode, the device can be returned to Program mode by using a Program Resume command.

In the program suspend mode, protect/unprotect command is prohibited.

While program can be suspended and resumed multiple times, a minimum 30us is required from resume to the next suspend.

9.22 Read While Write Operation

The device is capable of reading data from one bank while writing in the other banks. This is so called the Read While Write operation. An erase operation may also be suspended to read from or program to another location within the same bank (except the block being erased). The Read While Write operation is prohibited during the chip erase operation. Figure 19 shows how read and write cycles may be initiated for simultaneous operation with zero latency. Refer to the DC Characteristics table for read-while-write current specifications.

9.23 OTP Block Region

The OTP Block feature provides a 512-word Flash memory region that enables permanent part identification through an Electronic Serial Number (ESN). The OTP Block is customer lockable and shipped with itself unlocked, allowing customers to utilize the that block in any manner they choose. The customer-lockable OTP Block has the Protection Verify Bit (DQ0) set to a "0" for Unlocked state or a "1" for Locked state.

The system accesses the OTP Block through a command sequence (see "Enter OTP Block / Exit OTP Block Command sequence" at Table 8). After the system has written the "Enter OTP Block" Command sequence, it may read the OTP Block by using the addresses (1FFFE00h~1FFFFFFh : Top Boot block device/Uniform block device, 0000000h-00001FFh : Bottom Boot block device) normally and may check the Protection Verify Bit (DQ0) by using the "Autoselect Block Protection Verify" Command sequence with OTP Block address. This mode of operation continues until the system issues the "Exit OTP Block" Command sequence, a hardware reset or until power is removed from the device. On power-up, or following a hardware reset, the device reverts to sending commands to main blocks. Note that the Accelerated function and unlock bypass modes are not available when the OTP Block is enabled.

Customer Lockable

In a Customer lockable device, The OTP Block is one-time programmable and can be locked only once. Note that the Accelerated programming and Unlock bypass functions are not available when programming the OTP Block. Locking operation to the OTP Block is started by writing the "Enter OTP Block" Command sequence, and then the "Block Protection" Command sequence (Table 8) with an OTP Block address. The Locking operation has to be above 100us. "Exit OTP Block" command sequence and Hardware reset makes locking operation finished and then exiting from OTP Block after 30us.

The OTP Block Lock operation must be used with caution since, once locked, there is no procedure available for unlocking and none of the bits in the OTP Block space can be modified in any way.

Suspend and resume operation are not supported during OTP protect, nor is OTP protect supported during any suspend operations.

After entering OTP block, program/erase operation on main blocks is prohibited. Enter OTP block command is not allowed while other operation is executing.

9.24 Low V_{CC} Write Inhibit

To avoid initiation of a write cycle during V_{CC} power-up and power-down, a write cycle is locked out for V_{CC} less than V_{LKO} . If the $V_{CC} < V_{LKO}$ (Lock-Out Voltage), the command register and all internal program/erase circuits are disabled. Under this condition the device will reset itself to the read mode. Subsequent writes will be ignored until the V_{CC} level is greater than V_{LKO} . It is the user's responsibility to ensure that the control pins are logically correct to prevent unintentional writes when V_{CC} is above V_{LKO} .

9.25 Write Pulse "Glitch" Protection

Noise pulses of less than 5ns (typical) on OE, CE, \overline{AVD} or WE do not initiate a write cycle.

9.26 Logical Inhibit

Write cycles are inhibited by holding any one of OE = VIL, CE = VIH or WE = VIH. To initiate a write cycle, CE and WE must be a logical zero while OE is a logical one

10.0 FLASH MEMORY STATUS FLAGS

The K8A(10/11/12/13)15E has means to indicate its status of operation in the bank where a program or erase operation is in processes. Address must include bank address being executed internal routine operation. The status is indicated by raising the device status flag via corresponding DQ pins. The status data can be read during burst read mode by using \overline{AVD} signal with a bank address. That means status read is supported in synchronous mode. If status read is performed, the data provided in the burst read is identical to the data in the initial access. To initiate the synchronous read again, a new address and \overline{AVD} pulse is needed after the host has completed status reads or the device has completed the program or erase operation. The corresponding DQ pins are DQ7, DQ6, DQ5, DQ3, DQ2 and DQ1.

[Table 15] Hardware Sequence Flags

| | Status | DQ7 | DQ6 | DQ5 | DQ3 | DQ2 | DQ1 | |
|-------------------------------|---------------------------|------------------------------|------------------|--------|------|-----------|----------------------|------|
| In Progress | Programming | $\overline{DQ7}$ | Toggle | 0 | 0 | 1 | 0 | |
| | Block Erase or Chip Erase | 0 | Toggle | 0 | 1 | Toggle | 0 | |
| | Erase Suspend Read | Erase Suspended Block | 1 | 1 | 0 | 0 | Toggle ¹⁾ | 0 |
| | Erase Suspend Read | Non-Erase Suspended Block | Data | Data | Data | Data | Data | Data |
| | Erase Suspend Program | Non-Erase Suspended Block | $\overline{DQ7}$ | Toggle | 0 | 0 | 1 | 0 |
| | Program Suspend Read | Program Suspended Block | DQ7 | 1 | 0 | 0 | Toggle ¹⁾ | 0 |
| | Program Suspend Read | Non- program Suspended Block | Data | Data | Data | Data | Data | Data |
| Exceeded Time Limits | Programming | $\overline{DQ7}$ | Toggle | 1 | 0 | No Toggle | 0 | |
| | Block Erase or Chip Erase | 0 | Toggle | 1 | 1 | NOTE2 | 0 | |
| | Erase Suspend Program | $\overline{DQ7}$ | Toggle | 1 | 0 | No Toggle | 0 | |
| Write-to-Buffer ³⁾ | BUSY state | $\overline{DQ7}$ | Toggle | 0 | 0 | No Toggle | 0 | |
| | Exceeded Timing Limits | $\overline{DQ7}$ | Toggle | 1 | 0 | No Toggle | 0 | |
| | ABORT State | $\overline{DQ7}$ | Toggle | 0 | 0 | No Toggle | 1 | |

NOTE :

1) DQ2 will toggle when the device performs successive read operations from the erase/program suspended block.

2) If DQ5 is High (exceeded timing limits), successive reads from a problem block will cause DQ2 to toggle.

3) Note that DQ7 during Write-to-Buffer-Programming indicates the data-bar for DQ7 data for the last loaded write-buffer address location.

DQ7 : Data Polling

When an attempt to read the device is made while executing the Internal Program, the complement of the data is written to DQ7 as an indication of the Routine in progress. When the Routine is completed an attempt to access to the device will produce the true data written to DQ7. When a user attempts to read the block being erased or bank contains the block, DQ7 will be low. If the device is placed in the Erase/Program Suspend Mode, the status can be detected via the DQ7 pin. If the system tries to read an address which belongs to a block that is being erase suspended, DQ7 will be high. And, if the system tries to read an address which belongs to a block that is being program suspended, the output will be the true data of DQ7 itself. If a non-erase-suspended or non-program-suspended block address is read, the device will produce the true data to DQ7. If an attempt is made to program a protected block, DQ7 outputs complements the data for approximately 2us and the device then returns to the Read Mode without changing data in the block. If an attempt is made to erase a protected block, DQ7 outputs complement data in approximately 100us and the device then returns to the Read Mode without erasing the data in the block.

DQ6 : Toggle Bit

Toggle bit is another option to detect whether an Internal Routine is in progress or completed. Once the device is at a busy state, DQ6 will toggle. Toggling DQ6 will stop after the device completes its Internal Routine. If the device is in the Erase/Program Suspend Mode, an attempt to read an address that belongs to a block that is being erased or programmed will produce a high output of DQ6. If an address belongs to a block that is not being erased or programmed, toggling is halted and valid data is produced at DQ6. If an attempt is made to program a protected block, DQ6 toggles for approximately 2us and the device then returns to the Read Mode without changing the data in the block. If an attempt is made to erase a protected block, DQ6 toggles for approximately 100 μ s and the device then returns to the Read Mode without erasing the data in the block. #OE or #CE should be toggled in each toggle bit status read.

DQ5 : Exceed Timing Limits

If the Internal Program/Erase Routine extends beyond the timing limits, DQ5 will go High, indicating program/erase failure.

DQ3 : Block Erase Timer

The status of the multi-block erase operation can be detected via the DQ3 pin. DQ3 will go High if 50 μ s of the block erase time window expires. In this case, the Internal Erase Routine will initiate the erase operation. Therefore, the device will not accept further write commands until the erase operation is completed. DQ3 is Low if the block erase time window is not expired. Within the block erase time window, an additional block erase command (30H) can be accepted. To confirm that the block erase command has been accepted, the software may check the status of DQ3 following each block erase command.

DQ2 : Toggle Bit 2

The device generates a toggling pulse in DQ2 only if an Internal Erase Routine or an Erase/Program Suspend is in progress. When the device executes the Internal Erase Routine, DQ2 toggles if the bank including an erasing block is read. Although the Internal Erase Routine is in the Exceeded Time Limits, DQ2 toggles only if an erasing block in the Exceeded Time Limits is read. When the device is in the Erase/Program Suspend mode, DQ2 toggles only if an address in the erasing or programming block is read. If a non-erasing or non-programmed block address is read during the Erase/Program Suspend mode, then DQ2 will produce valid data. DQ2 will go High if the user tries to program a non-erase suspend block while the device is in the Erase Suspend mode. #OE or #CE should be toggled in each toggle bit status read.

DQ1 : Buffer Program Abort Indicator

DQ1 indicates whether a Write-to-Buffer operation was aborted. Under these conditions DQ1 produces a "1". The system must issue the Write-to-Buffer-Abort-Reset command sequence to return the device to reading array data.

RDY: Ready

Normally the RDY signal is used to indicate if new burst data is available at the rising edge of the clock cycle or not. If RDY is low state, data is not valid at expected time, and if high state, data is valid. Note that, if CE is low and OE is high, the RDY is high state.

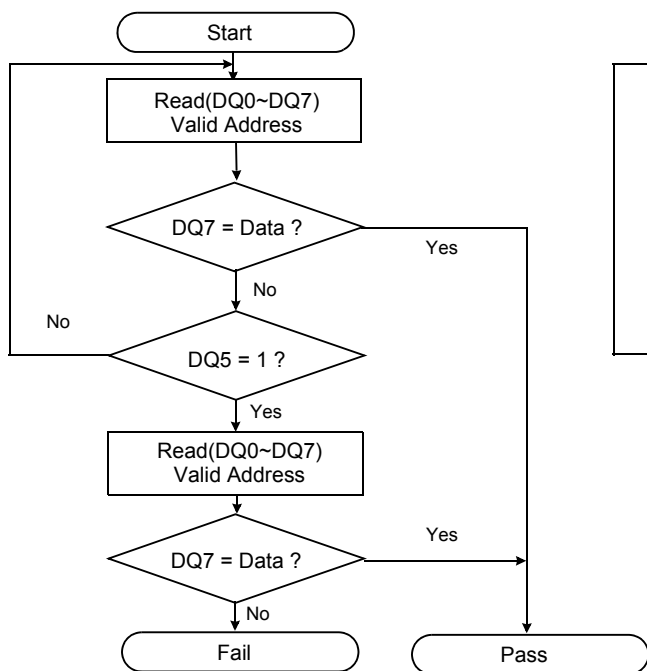

Figure 1. Data Polling Algorithms

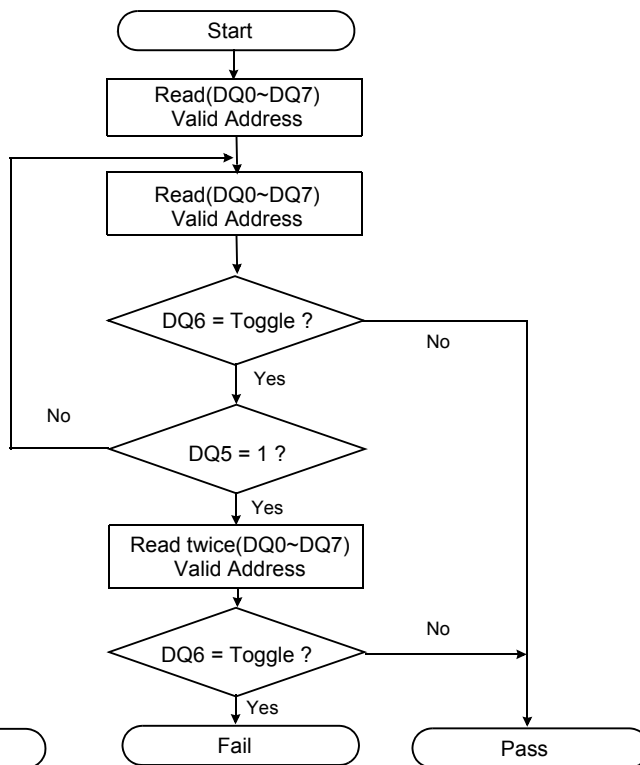

Figure 2. Toggle Bit Algorithms

11.0 DEEP POWER DOWN

In order to reduce the power consumption of the device, it shall a deep power down mode implemented on a separate pin. The deep power down mode is active when the deep power down signal is activated, high state. In deep power down the device shall turn off all circuitry in order to reach a power consumption of 2uA(typ). The device shall exit the deep power down mode within 75us after that the deep power down signal has been de-activated, set to low. In deep power down the state of the device chip select shall have no impact on the device power consumption. All programming capabilities of the device are inhibited.

At the power up, the device shall accept any order of activation of the reset and deep power down signal. The device shall respond within the specified time for the signal that was deactivated/activated latest. The deep power down mode is activated when DPD pin high state only. If DPD is asserted during a program or erase operation, the device requires a time of tDP (During Internal Routines) before the device is ready to enter DPD mode.

Note that user never float the DPD that is, DPD is always connected with VIH, VIL. Deep Power Down (DPD)

| Parameter | Symbol | All Speed Options | | | Unit |
|--|--------|-------------------|-----|-----|------|
| | | Min | Typ | Max | |
| DPD Pin High (NOT During Internal Routines) to DPD Mode* | tDP | 100 | - | - | ns |
| DPD Pin High (During Internal Routines) to DPD Mode* | tDP | 20 | - | - | μs |
| DPD Low Time Before Read* | twkup | 75 | - | - | μs |

NOTE :
Not 100% tested.

SWITCHING WAVEFORMS

Figure 3. DPD Timings

12.0 COMMON FLASH MEMORY INTERFACE

Common Flash Memory Interface is contrived to increase the compatibility of host system software. It provides the specific information of the device, such as memory size and electrical features. Once this information has been obtained, the system software will know which command sets to use to enable flash writes, block erases, and control the flash component.

When the system writes the CFI command(98H) to address 55H, the device enters the CFI mode. And then if the system writes the address shown in Table 16, the system can read the CFI data. Query data are always presented on the lowest-order data outputs(DQ0-7) only. In word(x16) mode, the upper data outputs(DQ8-15) is 00h. To terminate this operation, the system must write the reset command.

[Table 16] Common Flash Memory Interface Code

| Description | Addresses (Word Mode) | Data |
|---|--------------------------|----------------------------------|
| Query Unique ASCII string "QRY" | 10H 11H 12H | 0051H 0052H 0059H |
| Primary OEM Command Set | 13H 14H | 0002H 0000H |

13.0 ABSOLUTE MAXIMUM RATINGS

| Parameter | Symbol | Rating | Unit |
|------------------------------------|--------------------------|--------------|------|
| Voltage on any pin relative to VSS | V_{CC} | -0.5 to +2.5 | V |
| | V_{PP} | -0.5 to +9.5 | |
| | All Other Pins | -0.5 to +2.5 | |
| Storage Temperature | T_{stg} | -65 to +100 | °C |
| Short Circuit Output Current | I_{OS} | 5 | mA |
| Operating Temperature | T_A (Commercial Temp.) | 0 to +70 | °C |
| | T_A (Extended Temp.) | -25 to +85 | °C |

NOTE :

- 1) Minimum DC voltage is -0.5V on Input/ Output pins. During transitions, this level may fall to -2.0V for periods <20ns.
Maximum DC voltage is $V_{CC}+0.6V$ on input / output pins which, during transitions, may overshoot to $V_{CC}+2.0V$ for periods <20ns.
- 2) Minimum DC input voltage is -0.5V on V_{PP} . During transitions, this level may fall to -2.0V for periods <20ns.
Maximum DC input voltage is +9.5V on V_{PP} which, during transitions, may overshoot to +12.0V for periods <20ns.
- 3) Permanent device damage may occur if ABSOLUTE MAXIMUM RATINGS are exceeded. Functional operation should be restricted to the conditions detailed in the operational sections of this data sheet. Exposure to absolute maximum rating conditions for extended periods may affect reliability.

14.0 RECOMMENDED OPERATING CONDITIONS (Voltage reference to GND)

| Parameter | Symbol | Min | Typ. | Max | Unit |
|----------------|----------|-----|------|------|------|
| Supply Voltage | V_{CC} | 1.7 | 1.8 | 1.95 | V |
| Supply Voltage | V_{SS} | 0 | 0 | 0 | V |

NOTE :

- 1) Data retention is not guaranteed on Operating condition Extended temperature(-25°C~85°C) over.

15.0 DC CHARACTERISTICS

| Parameter | Symbol | Test Conditions | Min | Typ | Max | Unit |
|------------------------------------|------------|---|--------------|-----|--------------|---------|
| Input Leakage Current | I_{LI} | $V_{IN}=V_{SS}$ to V_{CC} , $V_{CC}=V_{CCmax}$ | - 1.0 | - | + 1.0 | μA |

| Data Setup Time | t_{DS} | 30 | - | - | ns |
| Data Hold Time | t_{DH} | 0 | - | - | ns |
| Read Recovery Time Before Write | t_{GHWL} | 0 | - | - | ns |
| \overline{CE} Setup Time | t_{CS} | 0 | - | - | ns |
| \overline{CE} Hold Time | t_{CH} | 0 | - | - | ns |
| \overline{WE} Pulse Width | t_{WP} | 30 | - | - | ns |
| \overline{WE} Pulse Width High | t_{WPH} | 45 | - | - | ns |
| Latency Between Read and Write Operations | t_{SRW} | 0 | - | - | ns |
| Word Programming Operation ²⁾ | t_{PGM} | - | 80 | - | μ s |
| Single word Buffer Program ²⁾ | t_{PGM_BP} | - | 250 | - | μ s |
| 512-word Buffer Program ³⁾ | t_{PGM_BP} | - | 716.8 | - | μ s |
| Accelerated Programming Operation | t_{ACCPGM} | - | 80 | - | μ s |
| Accelerated Single word Buffer Program | t_{ACCPGM_BP} | - | 0.7 | - | μ s |
| Accelerated 512-word Buffer Program ³⁾ | t_{ACCPGM_BP} | - | 358.4 | - | μ s |
| Block Erase Operation (64KW block) | t_{BERS} | - | 0.6 | - | sec |
| VPP Rise and Fall Time | t_{VPP} | 500 | - | - | ns |
| VPP Setup Time (During Accelerated Programming) | t_{VPS} | 1 | - | - | μ s |

NOTE :

1) Not 100% tested.

2) Internal programming algorithm is optimized for Buffer Program, so Normal word programming or Single word Buffer Program use Buffer Program algorithm.

3) Typical 512-word Buffer Program time pays due regard to that Each program data pattern ("11", "10", "01", "00") has a same portion in 512-word Buffer.

18.4 Erase/Program Performance

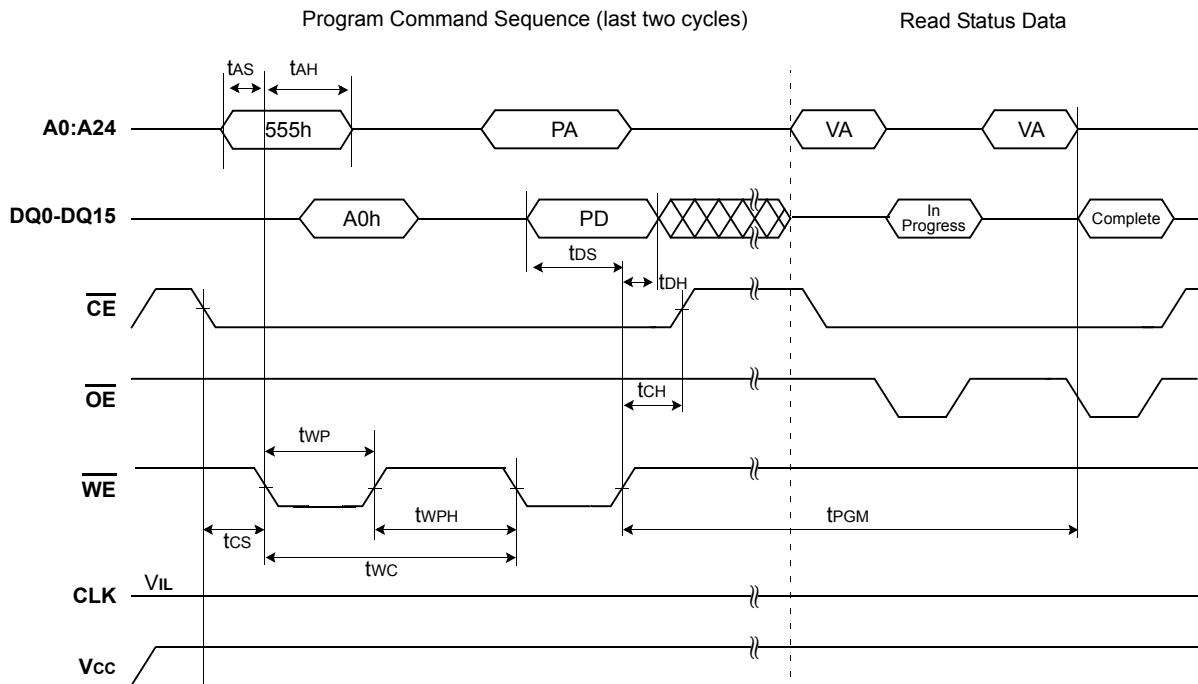

| Parameter | | Limits | | | Unit | Comments |
|--|----------|--------|-------|-------|-----------|---|
| | | Min. | Typ. | Max. | | |
| Block Erase Time | 64 Kword | - | 0.6 | 3.0 | sec | Includes 00h programming prior to erasure |
| | 16 Kword | - | 0.3 | 1.5 | | |
| Chip Erase Time ³⁾ | | - | 307.8 | 1539 | | |
| Accelerated Block Erase Time ⁴⁾ | 64 Kword | - | 0.4 | 3.0 | | |
| | 16 Kword | - | 0.2 | 1.5 | | |
| Accelerated Chip Erase Time ^{3),4)} | | - | 205.2 | 1026 | | |
| Word Programming Time | | - | 80 | 550 | µs / word | Excludes system level overhead |
| 512-word Buffer Programming Time | | - | 1.4 | 7 | | |
| Accelerated Word Programming Time | | - | 80 | 550 | | |
| Accelerated 512-word Buffer Programming Time | | - | 0.7 | 3.5 | | |
| Chip Buffer Programming Time | | - | 46.9 | 234.5 | sec | Excludes system level overhead |
| Accelerated Buffer Chip Programming Time | | - | 23.4 | 117 | | |

NOTE :

- 1) 25°C, VCC = 1.8V, 100,000 cycles, typical pattern.
- 2) System-level overhead is defined as the time required to execute the two or four bus cycle command necessary to program each word.
- 3) Chip Erase time & Accel. Chip Erase time for boot block part : K8A(10/11/12/13)15ET(B)C
- 4) Accelerated Program/Erase cycling must be limited below 100cycles for optimum performance. Ambient temperature requirements : TA = 30°C±10°C

SWITCHING WAVEFORMS

Program Operations

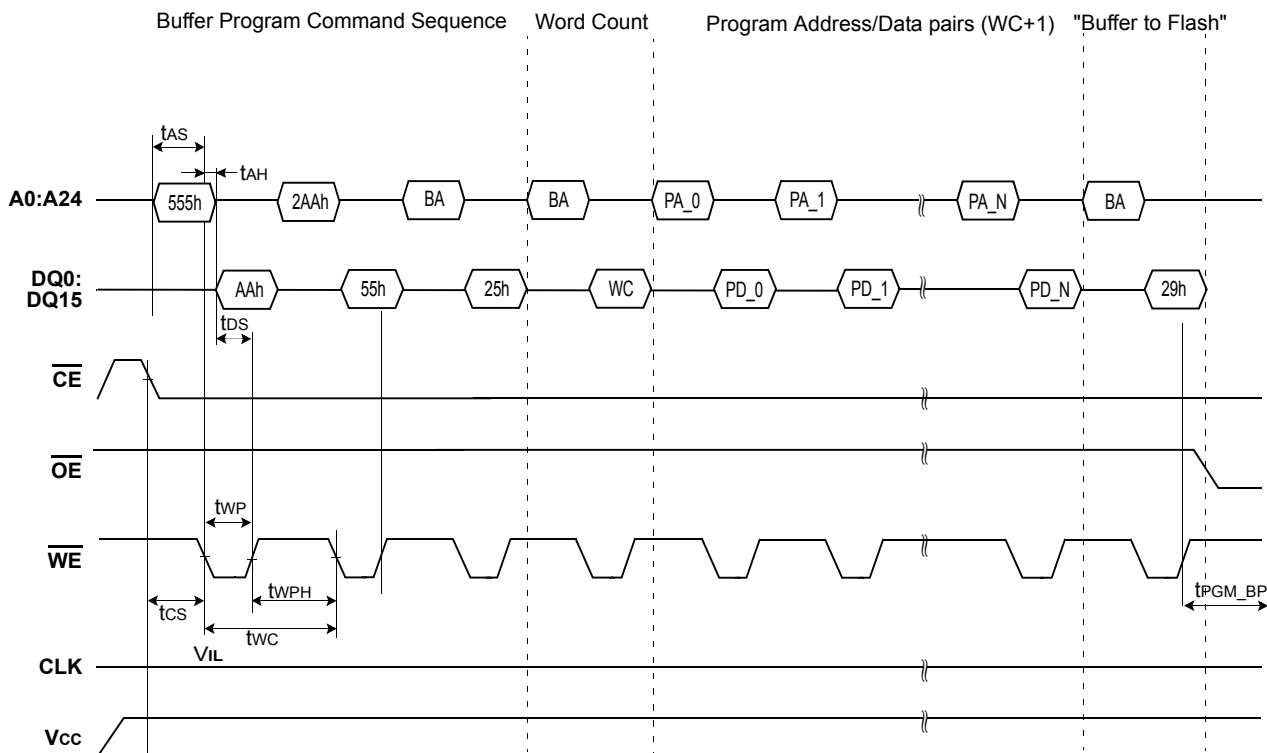

NOTE :

- 1) PA = Program Address, PD = Program Data, VA = Valid Address for reading status bits.
- 2) "In progress" and "complete" refer to status of program operation.
- 3) A16-A24 are don't care during command sequence unlock cycles.
- 4) Status reads in this figure is asynchronous read, but status read in synchronous mode is also supported.

Figure 13. Program Operation Timing

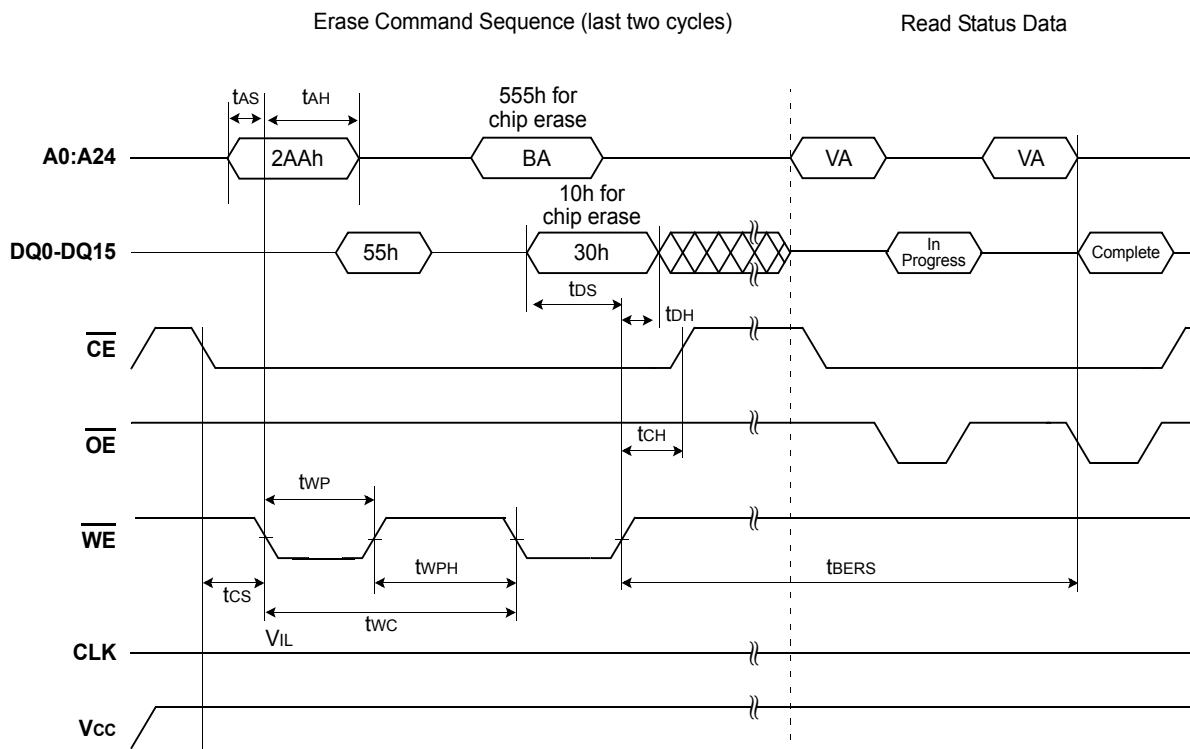

SWITCHING WAVEFORMS
Buffer Program Operations

- NOTE :**
- 1) BA = Block Address, WC = Word Count, PA = Program Address, PD = Program Data, VA = Valid Address for reading status bits.
 - 2) Sequential PA₁, PA₂, ..., PA_N must have same address bits A24(max.) ~ A9 as PA₀ entered firstly
 - 3) The number of Program/Data pairs entered must be same as WC+1 because WC = N.
 - 4) "In progress" and "complete" refer to status of program operation.
 - 5) A16-A24 are don't care during command sequence unlock cycles.
 - 6) Status reads in this figure is asynchronous read, but status read in synchronous mode is also supported.

Figure 14. Buffer Program Operation Timing

SWITCHING WAVEFORMS
Erase Operation

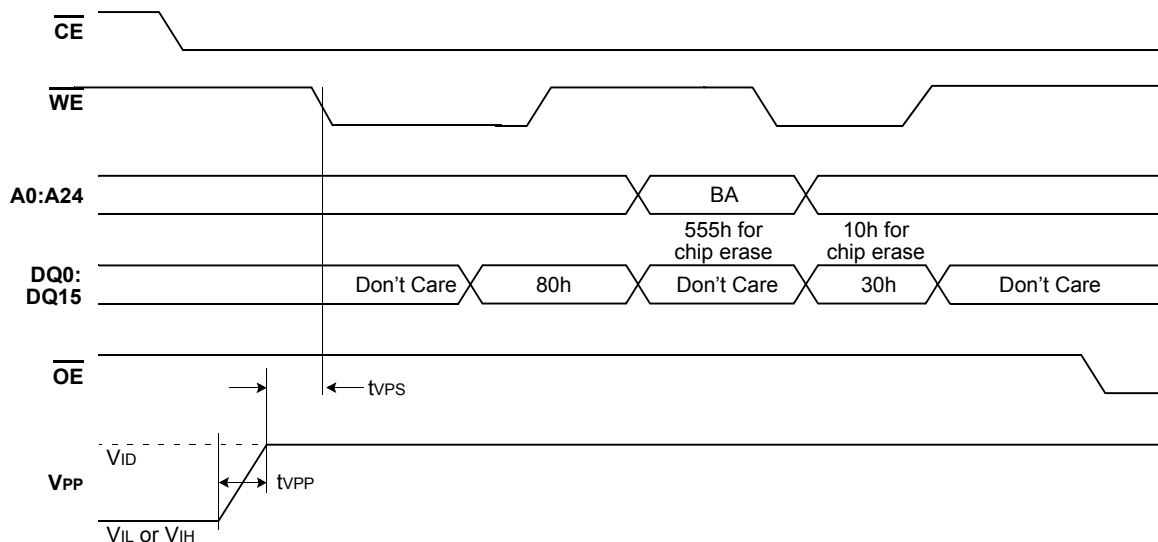

- NOTE :**
- 1) BA is the block address for Block Erase.
 - 2) Address bits A16-A24 are don't cares during unlock cycles in the command sequence.
 - 3) Status reads in this figure is asynchronous read, but status read in synchronous mode is also supported.

Figure 15. Chp/Block Erase Operations

SWITCHING WAVEFORMS
Unlock Bypass Program Operations (Accelerated Program)

Unlock Bypass Block Erase Operations

- NOTE :**
- 1) V_{PP} can be left high for subsequent programming pulses.
 - 2) Use setup and hold times from conventional program operations.
 - 3) Conventional Program/Erase commands as well as Unlock Bypass Program/Erase commands can be used when the V_{ID} is applied to V_{pp} .

Figure 16. Unlock Bypass Operation Timings

SWITCHING WAVEFORMS

Data Polling Operations

NOTE :
 1) VA = Valid Address. When the Internal Routine operation is complete, and \overline{Data} Polling will output true data.

Figure 17. Data Polling Timings (During Internal Routine)

Toggle Bit Operations

NOTE :
 1) VA = Valid Address. When the Internal Routine operation is complete, the toggle bits will stop toggling.

Read While Write Operations

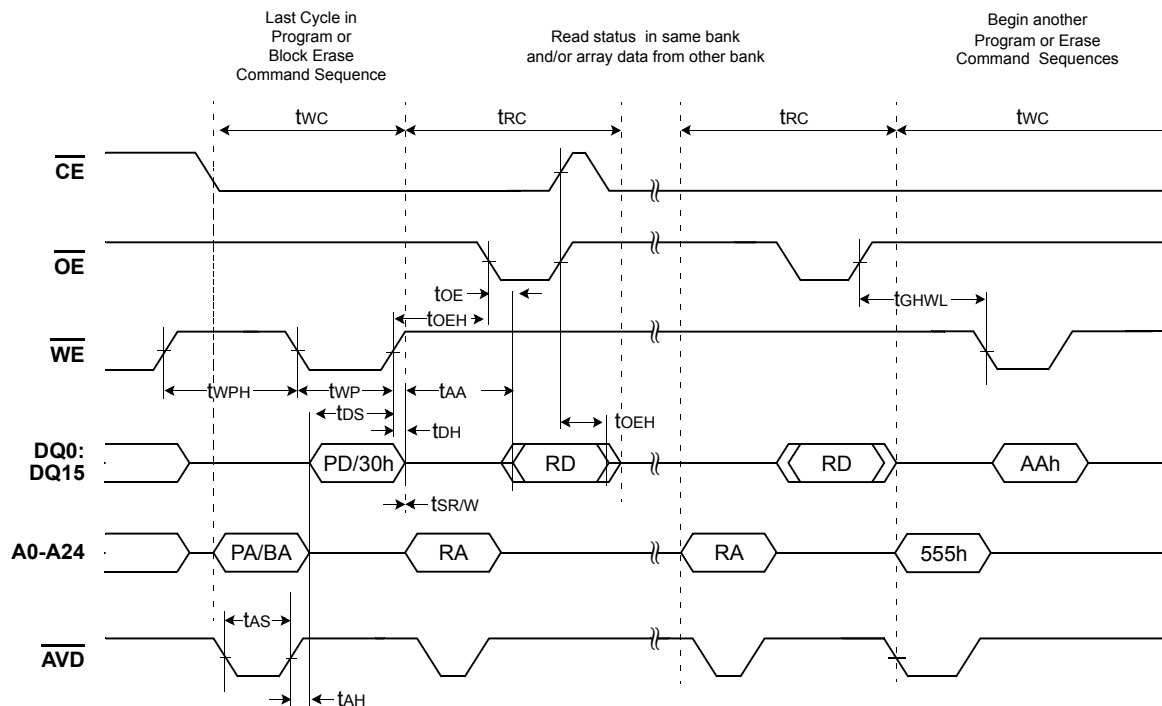

Figure 19. Read While Write Operation

NOTE : Breakpoints in waveforms indicate that system may alternately read array data from the "non-busy bank" and checking the status of the program or erase operation in the "busy" bank.

19.0 CROSSING OF FIRST WORD BOUNDARY IN BURST READ MODE

The additional clock insertion for word boundary is needed only at the first crossing of word boundary. This means that no additional clock cycle is needed from 2nd word boundary crossing to the end of continuous burst read. Also, the number of additional clock cycle for the first word boundary can varies from zero to thirteen cycles, and the exact number of additional clock cycle depends on the starting address of burst read and programmable wait state settings.

For example, if the starting address is $16N+15$ (the worst case) and programmable wait state setting(A<14:11>) is "0011" (which means data is valid on the 7th active CLK edge after \overline{AVD} transition to V_{ih}), six additional clock cycle is needed.

Similarly, if the starting address is $16N+15$ (the worst case) and programmable wait state setting(A<14:11>) is "0010" (which means data is valid on the 6th active CLK edge after \overline{AVD} transition to V_{ih}), five additional clock cycle is needed.

Below table shows the starting address vs. additional clock cycles for first word boundary.

Starting Address vs. Additional Clock Cycles for first word boundary

| Starting Address Group for Burst Read | The Residue of (Address/16) | LSB Bits of Address | Additional Clock Cycles for First Word Boundary (note1) | | | | |
|---------------------------------------|-----------------------------|---------------------|---|---|---|-----|--|
| | | | A<14:11> "0000" Valid data : 4th CLK | A<14:11> "0001" Valid data : 5th CLK | A<14:11> "0010" Valid data : 6th CLK | ... | A<14:11> "1010" Valid data : 14th CLK |
| 16N | 0 | 0000 | 0 cycle | 0 cycle | 0 cycle | ... | 0 cycle |
| 16N+1 | 1 | 0001 | 0 cycle | 0 cycle | 0 cycle | ... | 0 cycle |
| 16N+2 | 2 | 0010 | 0 cycle | 0 cycle | 0 cycle | ... | 0 cycle |
| 16N+3 | 3 | 0011 | 0 cycle | 0 cycle | 0 cycle | ... | 1 cycle |
| 16N+4 | 4 | 0100 | 0 cycle | 0 cycle | 0 cycle | ... | 2 cycle |
| 16N+5 | 5 | 0101 | 0 cycle | 0 cycle | 0 cycle | ... | 3 cycle |
| 16N+6 | 6 | 0110 | 0 cycle | 0 cycle | 0 cycle | ... | 4 cycle |
| 16N+7 | 7 | 0111 | 0 cycle | 0 cycle | 0 cycle | ... | 5 cycle |
| 16N+8 | 8 | 1000 | 0 cycle | 0 cycle | 0 cycle | ... | 6 cycle |
| 16N+9 | 9 | 1001 | 0 cycle | 0 cycle | 0 cycle | ... | 7 cycle |
| 16N+10 | 10 | 1010 | 0 cycle | 0 cycle | 0 cycle | ... | 8 cycle |
| 16N+11 | 11 | 1011 | 0 cycle | 0 cycle | 1 cycle | ... | 9 cycle |
| 16N+12 | 12 | 1100 | 0 cycle | 1 cycle | 2 cycle | ... | 10 cycle |
| 16N+13 | 13 | 1101 | 1 cycle | 2 cycle | 3 cycle | ... | 11 cycle |
| 16N+14 | 14 | 1110 | 2 cycle | 3 cycle | 4 cycle | ... | 12 cycle |
| 16N+15 | 15 | 1111 | 3 cycle | 4 cycle | 5 cycle | ... | 13 cycle |

NOTE :

Address bit A<14:11> means the programmable wait state on burst mode configuration register. Refer to Table 10.

Case 1 : Start from "16N" address group

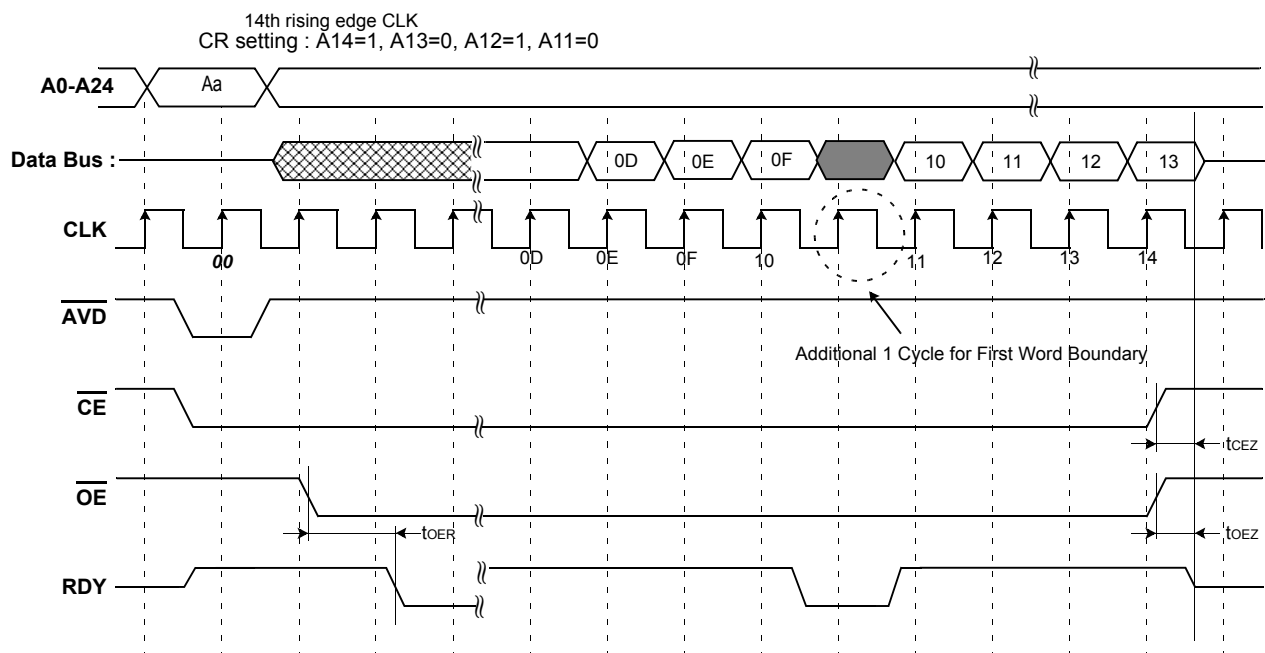

NOTE :

- 1) Address boundary occurs every 16 words beginning at address 000000FH, 000001FH, 000002FH, etc.
- 2) Address 000000H is also a boundary crossing.
- 3) No additional clock cycles are needed except for 1st boundary crossing.

Figure 20. Crossing of first word boundary in burst read mode.

Case 2 : Start from "16N+3" address group

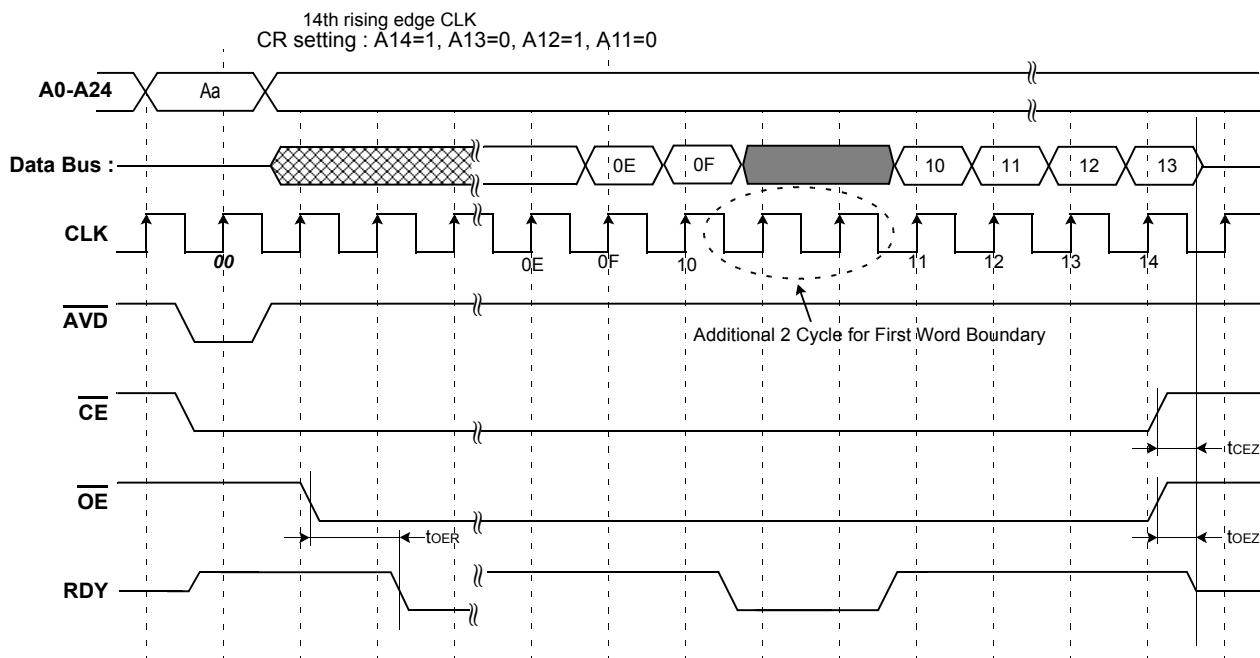

NOTE :

- 1) Address boundary occurs every 16 words beginning at address 000000FH, 000001FH, 000002FH, etc.
- 2) Address 000000H is also a boundary crossing.
- 3) No additional clock cycles are needed except for 1st boundary crossing.

Figure 21. Crossing of first word boundary in burst read mode.

Case3 : Start from "16N+4" address group

Case 4 : Start from "16N+15" address group

- NOTE :**
- 1) Address boundary occurs every 16 words beginning at address 000000FH, 000001FH, 000002FH, etc.
 - 2) Address 000000H is also a boundary crossing.
 - 3) No additional clock cycles are needed except for 1st boundary crossing.

Figure 22. Crossing of first word boundary in burst read mode.
