## CMOS 8-BIT MICROCONTROLLER

# TMP87CH37N, TMP87CK37N, TMP87CM37N

The 87CH37/K37/M37 are the high speed and high performance 8-bit single chip microcomputers. These MCU contain CPU core, ROM, RAM, input / output ports, six multi-function timer / counters, serial bus interface, onscreen display, PWM outputs, 6-bit A/D conversion inputs, remote control signal preprocessor, and two clock generators on a chip.

PART No.	ROM	RAM	PACKAGE	OTP
TMP87CH37N	16K bytes			
TMP87CK37N	24K bytes	1K bytes	SDIP64	TMP87PM37N
TMP87CM37N	32K bytes			

#### **FEATURES**

◆8-bit single chip microcomputer TLCS-870 Series

lacktriangle Instruction execution time : 0.5  $\mu$ s (at 8 MHz), 122  $\mu$ s (at 32.768 kHz)

412 basic instructions

Multiplication and Division (8 bits x 8 bits, 16 bits ÷ 8 bits)

Bit manipulations
 (Set / Clear / Complete)

(Set / Clear / Complement / Move / Test / Exclusive or)

• 16-bit data operations

• 1-byte jump / subroutine-call (Short relative jump / Vector call)

◆15 interrupt sources (External: 6, Internal: 9

 All sources have independent latches each, and nested interrupt control is available.

• 4 edge-selectable external interrupts with noise reject

High-speed task switching by register bank changeover

◆8 Input / Output ports (56 pins)

• High current output: 4 pins (typ. 20 mA)

◆Two 16-bit Timer / Counters 🔍

Timer, Event counter, Programmable pulse generator output,
 Pulse width measurement, External trigger timer, Window modes

◆Two 8-bit Timer / Counters

• Timer, Event counter, Capture (Pulse width / duty measurement) modes

◆Time Base Timer (Interrupt frequency: 1 Hz to 16 kHz)

◆ Divider output function (frequency: 1 kHz to 8 kHz)

◆Watchdog Timer

• Interrupt source / reset output (programmable)

Serial Bus Interface

• I2C-bus, 8-bit SIO modes

On-screen display circuit

Character patterns
 Characters displayed
 128 characters
 24 columns × 12 lines

• Composition : 14 x 18 dots

• Size of character : 3 kinds (line by line)

Color of character : 8 kinds (character by character)

Variable display position : Horizontal 128 steps, Vertical 256 steps

• Fringing, Smoothing function

D/A conversion (Pulse Width Modulation) outputs

• 14-bit resolution (1 channel)

• 7-bit resolution (9 channels)

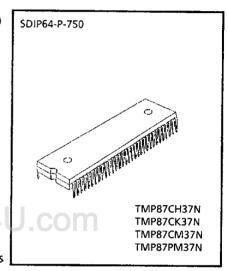

6-bit A/D conversion input (4 channels)

◆Pulse output (Clock for PLL IC)

Remote control signal preprocessor

◆ Dual clock operation

Single/Dual-clock mode (option)

◆Five Power saving operating modes

• STOP mode: Oscillation stops. Battery / Capacitor back-up. Port output hold / high-impedance.

• SLOW mode: Low power consumption operation using low-frequency clock (32.768 kHz).

• IDLE1 mode: CPU stops, and Peripherals operate using high-frequency clock. Release by interrupts.

• IDLE2 mode: CPU stops, and Peripherals operate using high and low frequency clock.

Release by interrupts.

• SLEEP mode: CPU stops, and Peripherals operate using low-frequency clock. Release by interrupts.

♦ Wide operating voltage : 2.7 to 5.5 V at 32.768 kHz, 4.5 to 5.5 V at 8 MHz / 32.768 kHz

◆Emulation Pod : BM87CM37N0A

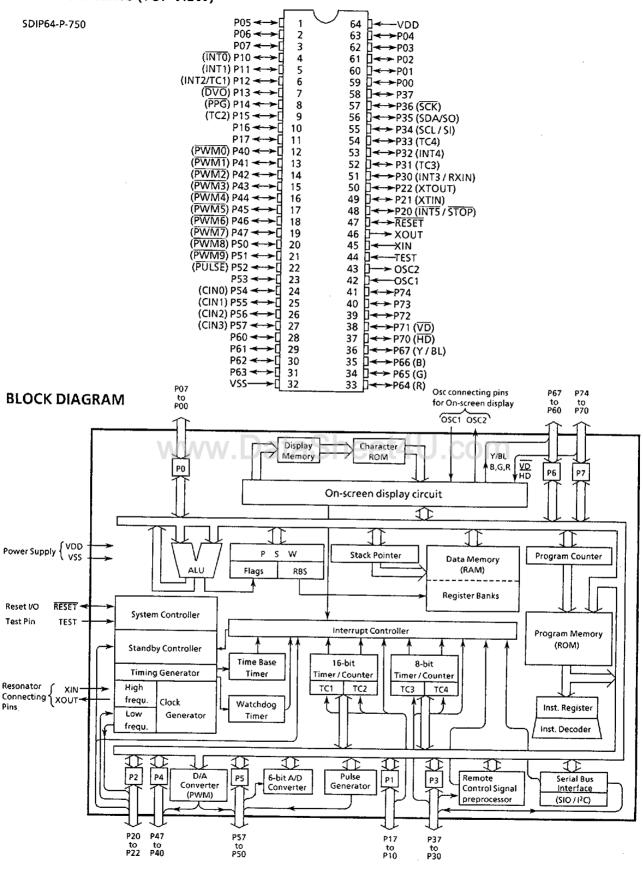

Purchase of TOSHIBA I<sup>2</sup> C components conveys a license under the Philips I<sup>2</sup> C Patent Rights to use these components in an I<sup>2</sup> C system, provided that the system conforms to the I<sup>2</sup> C Standard Specification as defined by Philips

## **OPERATIONAL DESCRIPTION**

#### 1. CPU CORE FUNCTIONS

The CPU core consists of a CPU, a system clock controller, an interrupt controller, and a watchdog timer. This section provides a description of the CPU core, the program memory (ROM), the data memory (RAM), and the reset circuit.

#### 1.1 Memory Address Map

The TLCS-870 Series is capable of addressing 64K bytes of memory. Figure 1-1 shows the memory address maps of the 87CH37/K37/M37. In the TLCS-870 Series, the memory is organized 4 address spaces (ROM, RAM, SFR, and DBR). It uses a memory mapped I/O system, and all I/O registers are mapped in the SFR / DBR address spaces. There are 16 banks of general-purpose registers. The register banks are also assigned to the first 128 bytes of the RAM address space.

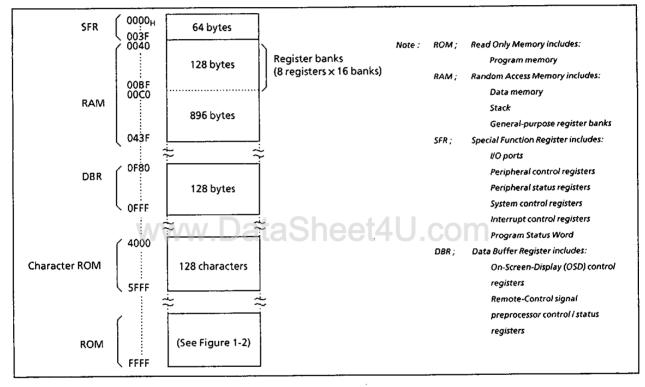

Figure 1-1. Memory Address Map

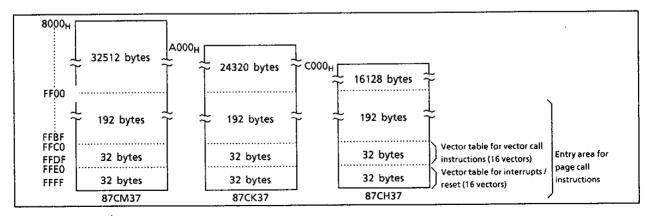

Figure 1-2. ROM Address Maps

3-37-6

## 1.2 Program Memory (ROM)

The 87CH37 has a 16K bytes (addresses  $C000_H$  to  $FFFF_H$ ), the 87CK37 has a 24K bytes (addresses  $A000_H$  to  $FFFF_H$ ), and the 87CM37 has a 32K bytes (addresses  $8000_H$  to  $FFFF_H$ ) of program memory (mask programmed ROM). Addresses  $FF00_H$  to  $FFFF_H$  in the program memory can also be used for special purposes. Figure 1-2 shows the ROM address maps of the 87CH37/K37/M37.

- (1) Interrupt / Reset vector table (addresses FFEO<sub>H</sub> to FFFF<sub>H</sub>)

  This table consists of a reset vector and 15 interrupt vectors (2 bytes/vector). These vectors store a reset start address and interrupt service routine entry addresses.
- (2) Vector table for vector call instructions (addresses FFCO<sub>H</sub> to FFDF<sub>H</sub>)

  This table stores call vectors (subroutine entry address, 2 bytes / vector) for the vector call instructions [CALLV n]. There are 16 vectors. The CALLV instruction increases memory efficiency when utilized for frequently used subroutine calls (called from 3 or more locations).
- (3) Entry area (addresses FF00<sub>H</sub> to FFFF<sub>H</sub>) for page call instructions

  This is the subroutine entry address area for the page call instructions [CALLP n]. Addresses FF00<sub>H</sub>
  FFBF<sub>H</sub> are normally used because address FFC0<sub>H</sub> to FFFF<sub>H</sub> are used for the vector tables.

Programs and fixed data are stored in the program memory. The instruction to be executed next is read from the address indicated by the current contents of the program counter (PC). There are relative jump and absolute jump instructions. The concepts of page or bank boundaries are not used in the program memory concerning any jump instruction.

Example: The relationship between the jump instructions and the PC.

- ① 5-bit PC-relative jump [JRS cc, \$+2+d] E8C4H: JRS T, \$+2+08H When JF = 1, the jump is made to E8CEH, which is 08H added to the contents of the PC. (The PC contains the address of the instruction being executed + 2; therefore, in this case, the PC contents are E8C4H + 2 = E8C6H.)
- S-bit PC-relative jump [JR cc, \$+2+d] E8C4H: JR Z, \$+2+80H When ZF = 1, the jump is made to E846H, which is FF80H (-128) added to the current contents of the PC.
- 3 16-bit absolute jump [JP a] E8C4H: JP 0C235H An unconditional jump is made to address C235H. The absolute jump instruction can jump anywhere within the entire 64K-bytes space.

Address ROM 8000<sub>H</sub> contents (A000) (C000) Example: The relationship between ROM Contents FF00 and Call group instructions/Interrupt/ Reset CALLP 7BH ; PC ← FF7B<sub>H</sub> FF7B FFBF FFC0 call vector (L) 56 CALLV OH ; PC ← C856H FFC1 call vector (H) **C8** FFC2 **FFDF** interrupt vector (L) 68 FFE0 INT5 ; PC ← D368<sub>H</sub> FFE1 interrupt vector (H) D3 FFE2 **FFFD** FFFE reset vector (L) 3E RESET ; PC ← CO3E<sub>H</sub> **FFFF** reset vector (H) C0

In the TLCS-870 Series, the same instruction used to access the data memory (e.g. [LD A,

Figure 1-3. Program Memory Map

(HL)]) is also used to read out fixed data (ROM data) stored in the program memory. The register-offset PC-relative addressing (PC + A) instructions can also be used, and the code conversion, table look-up and n-way multiple jump processing can easily be programmed.

SHLC A JP (PC+A)

SNEXT:

TABLE: DB

Notes: "\$" is a header address of ADD instruction.

DB is a byte data difinition instruction.

Example 3 : N-way multiple jump in accordance with the contents of

accumulator ( $0 \le A \le 3$ ):

SHLC A ; if  $A = 00_H$  then  $PC \leftarrow C234_H$ JP (PC + A) if  $A = 01_H$  then  $PC \leftarrow C378_H$ if  $A = 02_H$  then  $PC \leftarrow DA37_H$ 

if  $A = 03_H$  then  $PC \leftarrow E1B0_H$ 

DW 0C234H, 0C378H, 0DA37H, 0E1B0H

Note: DW is a word data definition instruction.

## 1.3 Program Counter (PC)

The program counter (PC) is a 16-bit register which indicates the program memory address where the instruction to be executed next is stored. After reset, the user defined reset vector stored in the vector table (addresses FFFF<sub>H</sub> and FFFE<sub>H</sub>) is loaded into the PC; therefore, program execution is possible from any desired address. For example, when CO<sub>H</sub> and 3E<sub>H</sub> are stored at addresses FFFF<sub>H</sub> and FFFE<sub>H</sub>, respectively, the execution starts from address CO3E<sub>H</sub> after reset.

The TLCS-870 Series utilizes pipelined processing (instruction pre-fetch); therefore, the PC always indicates 2 addresses in advance. For example, while a 1-byte instruction stored at address C123<sub>H</sub> is being executed, the PC contains C125<sub>H</sub>.

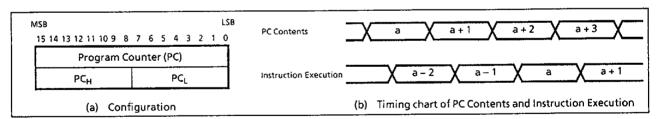

Figure 1-4. Program Counter

3-37-8

## Data Memory (RAM)

TOSHIBA

The 87CH37/K37/M37 have a 1K bytes (addresses  $0040_H$  to  $043F_H$ ) of data memory (static RAM). Figure 1-5 shows the data memory map.

Addresses 0000H to 00FFH are used as a direct addressing area to enhance instructions which utilize this addressing mode; therefore, addresses 0040H to 00FFH in the data memory can also be used for user flags or user counters. General-purpose register banks (8 registers x 16 banks) are also assigned to the 128 bytes of addresses 0040H to 00BFH. Access as data memory is still possible even when being used for registers. For example, when the contents of the data memory at address 0040H is read out, the contents of the accumulator in the bank 0 are also read out. The stack can be located anywhere within the data memory except the register bank area. The stack depth is limited only by the free data memory size. For more details on the stack, see section "1.7 Stack and Stack Pointer".

With the TLCS-870 series, programs in data memory cannot be executed. If the program counter indicates a specific data memory address an address-trap-reset is generated due to bus error. (Output from the RESET pin goes low.)

Example 1: If bit 2 at data memory address 00C0H is "1", 00H is written to data memory at address 00E3H; otherwise, FFH is written to the data memory at address 00E3H:

> **TEST** (00C0H).2

; if  $(00C0_H)_2 = 0$  then jump

JRS T.SZERO

(00E3H)

; (00E3<sub>H</sub>) ← 00<sub>H</sub>

**JRS** T, SNEXT

SZERO: LD (00E3H), 0FFH

CLR

; (00E3<sub>H</sub>) ← FF<sub>H</sub>

SNEXT:

Example 2:

Increments the contents of data memory at address 00F5<sub>H</sub>, and clears to 00<sub>H</sub> when

10<sub>H</sub> is exceeded:

(00F5H) INC

; (00F5<sub>H</sub>) ← (00F5<sub>H</sub>) + 1

AND (00F5H), 0FH  $\Rightarrow$  (00F5H)  $\leftarrow$  (00F5H) $\wedge$ 0FH

The data memory contents become unstable when the power supply is turned on; therefore, the data memory should be initialized by an initialization routine.

Note: The general-purpuse registers are mapped in the RAM; therefore, do not clear RAM at the current bank addresses.

Example : Clears RAM to "00H" except the bank 0:

> LD HL, 0048H

; Sets start address to HL register pair

LD A, H ; Sets initial data (00H) to A register

BC, 03F7H LD

; Sets number of byte to BC register pair

**SRAMCLR:** 

LD

(HL+), A

DEC BC

JRS F, SRAMCLR

3-37-9

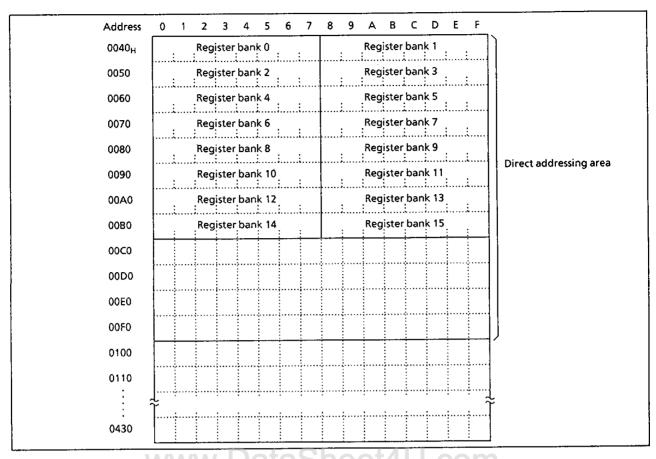

Figure 1-5. Data Memory Map

## 1.5 General-purpose Register Banks

General-purpose registers are mapped into addresses  $0040_{\rm H}$  to  $00BF_{\rm H}$  in the data memory as shown in Figure 1-5. There are 16 register banks, and each bank contains eight 8-bit registers W, A, B, C, D, E, H, and L. Figure 1-6 shows the general-purpose register bank configuration.

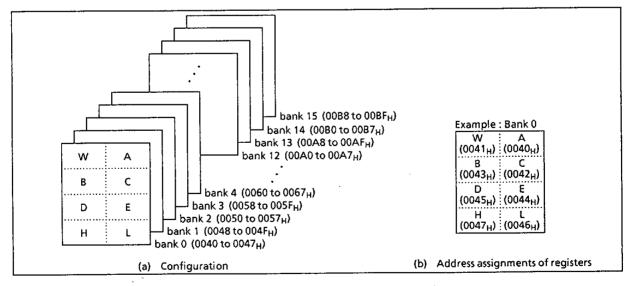

Figure 1-6. General-purpose Register Banks

3-37-10

www.DataSheet4U.com

DataSheet4U.com www.DataSheet4U.com

In addition to access in 8-bit units, the registers can also be accessed in 16-bit units as the register pairs WA, BC, DE, and HL. Besides its function as a general-purpose register, the register also has the following functions:

#### (1) A, WA

The A register functions as an 8-bit accumulator and WA the register pair functions as a 16-bit accumulator (W is high byte and A is low byte). Registers other than A can also be used as accumulators for 8-bit operations.

Examples:	① ADD ② SUB	•	<ul> <li>Adds B contents to A contents and stores the result into A.</li> <li>Subtracts 1234<sub>H</sub> from WA contents and stores the result into WA.</li> </ul>
	③ SUB	E, A	; Subtracts A contents from E contents, and stores the result into E.

#### (2) HL, DE

The HL and DE specify a memory address. The HL register pair functions as data pointer (HL) / index register (HL + d) / base register (HL + C), and the DE register pair function as a data pointer (DE). The HL also has an auto-post- increment and auto-pre-decrement functions. This function simplifies multiple digit data processing, software LIFO (last-in first-out) processing, etc.

```
Example 1: ① LD
                      A, (HL)
                                    ; Loads the memory contents at the address specified by HL
                                      into A.
            2 LD
                      A, (HL + 52H); Loads the memory contents at the address specified by the
                                      value obtained by adding 52H to HL contents into A.
            3 LD
                      A, (HL + C) ; Loads the memory contents at the address specified by the
                                      value obtained by adding the register C contents to HL
                                      contents into A.
                                    ; Loads the memory contents at the address specified by HL
                                      into A. Then increments HL.
            (S) LD
                      A, (-HL)
                                    ; Decrements HL. Then loads the memory contents at the
                                      address specified by new HL into A.
```

The TLCS-870 Series can transfer data directly memory to memory, and operate directly between memory data and memory data. This facilitates the programming of block processing.

```
Example 2: Block transfer
```

```
LD
                 B. n-1
                                    ; Sets (number of bytes to transfer) - 1 to B
        LD
                 HL, DSTA
                                    ; Sets destination address to HL
        LD
                 DE, SRCA
                                    ; Sets source address to DE
SLOOP: LD
                 (HL), (DE)
                                    ; (HL) ← (DE)
        INC
                 HL
                                    ; HL ← HL + 1
        INC
                 DΕ
                                    ; DE← DE + 1
        DEC
                                    ; B \leftarrow B - 1 JRS F, SLOOP ; if B \ge 0 then loop
```

## (3) B, C, BC

Registers B and C can be used as 8-bit buffers or counters, and the BC register pair can be used as a 16-bit buffer or counter. The C register functions as an offset register for register-offset index addressing (refer to example 1 3 above) and as a divisor register for the division instruction [DIV gg, C].

Example 1: Repeat processing

B, n LD

; Sets n as the number of repetitions to B

SREPEAT: processing (n + 1 times processing)

В DEC

JRS F, SREPEAT

Unsigned integer division (16-bit ÷ 8-bit) Example 2:

WA, C

; Divides the WA contents by the C contents, places the

quotient in A and the remainder in W.

The general-purpose register banks are selected by the 4-bit register bank selector (RBS). During reset, the RBS is initialized to "0". The bank selected by the RBS is called the current bank.

Together with the flag, the RBS is assigned to address 003FH in the SFR as the program status word (PSW). There are 3 instructions [LD RBS, n], [PUSH PSW] and [POP PSW] to access the PSW. The PSW can be also operated by the memory access instruction.

Example 1: Incrementing the RBS

INC (003FH) : RBS ← RBS + 1

Example 2:

Reading the RBS

LD A, (003FH) ;  $A \leftarrow PSW (A_{3-0} \leftarrow RBS, A_{7-4} \leftarrow Flags)$ 

Highly efficient programming and high-speed task switching are possible by using bank changeover to save registers during interrupt and to transfer parameters during subroutine processing.

During interrupt, the PSW is automatically saved onto the stack. The bank used before the interrupt was accepted is restored automatically by executing an interrupt return instruction [RETI] / [RETN]; therefore, there is no need for the RBS save / restore software processing.

The TLCS-870 Series supports a maximum of 15 interrupt sources. One bank is assigned to the main program, and one bank can be assigned to each source. Also, to increase the efficiency of data memory usage, assign the same bank to interrupt sources which are not nested.

: Saving / restoring registers during interrupt task using bank changeover.

; RBS ← n (Bank changeover) PINT1: LD RBS, n

Interrupt processing

; Maskable interrupt return (Bank restoring) RETI

## 1.6 Program Status Word (PSW)

The program status word (PSW) consists of a register bank selector (RBS) and four flags, and the PSW is assigned to address 003FH in the SFR.

The RBS can be read and written using the memory access instruction (e. g. [LD A, (003FH)], [LD (003FH), A], however the flags can only be read. When writing to the PSW, the change specified by the instruction is made without writing data to the flags. For example, when the instruction [LD (003FH), 05H] is executed, "5" is written to the RBS and the JF is set to "1", but the other flags are not affected. [PUSH PSW] and [POP PSW] are PSW access instructions.

### 1.6.1 Register Bank Selector (RBS)

The register bank selector (RBS) is a 4-bit register used to select general-purpose register banks. For example, when RBS = 2, bank 2 is currently selected. During reset, the RBS is initialized to "0".

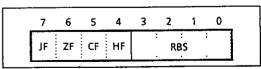

Figure 1-7. PSW (Flags, RBS) Configuration

3-37-12

## 1.6.2 Flags

TOSHIBA

The flags are configured with the upper 4 bits: a zero flag, a carry flag, a half carry flag and a jump status flag. The flags are set or cleared under conditions specified by the instruction. These flags except the half carry flag are used as jump condition "cc" for conditional jump instructions [JR cc, +2+d] / [JRS cc, +2+d]. After reset, the jump status flag is initialized to "1", other flags are not affected.

## (1) Zero flag (ZF)

The ZF is set to "1" if the operation result or the transfer data is 00H (for 8-bit operations and data transfers) /  $0000_H$  (for 16-bit operations); otherwise the ZF is cleared to "0".

During the bit manipulation instructions [SET, CLR, and CPL], the ZF is set to "1" if the contents of the specified bit is "0"; otherwise the ZF is cleared to "0".

This flag is set to "1" when the upper 8 bits of the product are 00H during the multiplication instruction [MUL], and when  $00_{\text{H}}$  for the remainder during the division instruction [DIV]; otherwise it is cleared to "0".

## (2) Carry flag (CF)

The CF is set to "1" when a carry out of the MSB (most significant bit) of the result occurred during addition or when a borrow into the MSB of the result occurred during subtraction; otherwise the CF is cleared to "0". During division, this flag is set to "1" when the divisor is 00H (divided by zero error), or when the quotient is 100H or higher (quotient overflow error); otherwise it is cleared. The CF is also affected during the shift / rotate instructions [SHLC, SHRC, ROLC, and RORC]. The data shifted out from a register is set to the CF.

This flag is also a 1-bit register (a boolean accumulator) for the bit manipulation instructions. Set / clear / complement are possible with the CF manipulation instructions.

Example 1 : Bit manipulation

LD CF, (0007H).5 ;  $(0001_{\text{H}})_2 \leftarrow (0007_{\text{H}})_5 \forall (009A_{\text{H}})_0$ 

XOR. CF, (009AH).0 LD (0001H).2, CF

Example 2: Arithmetic right shift

LD CF, A.7 ; A ← A/2

RORC A

## (3) Half carry flag (HF)

The HF is set to "1" when a carry occurred between bits 3 and 4 of the operation result during an 8bit addition, or when a borrow occurred from bit 4 into bit 3 of the result during an 8-bit subtraction; otherwise the HF is cleared to "0". This flag is useful in the decimal adjustment for BCD operations (adjustments using the [DAA r], or [DAS r] instructions).

Example : BCD operation

(The A becomes  $47_{H}$  after executing the following program when A =  $19_{H}$ , B =  $28_{H}$ )

ADD A, B ;  $A \leftarrow 41_H$ ,  $HF \leftarrow 1$ ,  $CF \leftarrow 0$ 

DAA ;  $A \leftarrow 41_H + 06_H = 47_H$  (decimal-adjust)

## (4) Jump status flag (JF)

Zero or carry information is set to the JF after operation (e. g. INC, ADD, CMP, TEST).

The JF provides the jump condition for conditional jump instructions [JRS T/F, +2+d], [JR T/F, +2+d] (T or F is a condition code). Jump is performed if the JF is "1" for a true condition (T), or the JF is "0" for a false condition (F).

The JF is set to "1" after executing the load / exchange / swap / nibble rotate/jump instruction, so that [JRS T, \$ + 2 + d] and [JR T, \$ + 2 + d] can be regarded as an unconditional jump instruction.

Example : Jump status flag and conditional jump instruction

INC A

:

JRS T, SLABLE1 ;

; Jump when a carry is caused by the immediately

preceding operation instruction.

LD A, (HL)

JRS T, SLABLE2

; JF is set to "1" by the immediately preceding

instruction, making it an unconditional jump

instruction.

Example: The accumulator and flags become as shown below after executing the following instructions when the WA register pair, the HL register pair, the data memory at address 00C5<sub>H</sub>, the carry flag and the half carry flag contents being "219A<sub>H</sub>", "00C5<sub>H</sub>", "D7<sub>H</sub>", "1" and "0", respectively.

Instruction		Acc. after	Flag after execution

SET A.5	BA	1	1	1	0

# 1.7 Stack and Stack Pointer

#### 1.7.1 Stack

The stack provides the area in which the return address or status, etc. are saved before a jump is performed to the processing routine during the execution of a subroutine call instruction or the acceptance of an interrupt. On a subroutine call instruction [CALL a] / [CALLP n] / [CALLV n], the contents of the PC (the return address) is saved; on an interrupt acceptance, the contents of the PC and the PSW are saved (the PSW is pushed first, followed by PCH and PCL). Therefore, a subroutine call occupies two bytes on the stack; an interrupt occupies three bytes.

When returning from the processing routine, executing a subroutine return instruction [RET] restores the contents to the PC from the stack; executing an interrupt return instruction [RETI] / [RETN] restores the contents to the PC and the PSW (the PC<sub>L</sub> is popped first, followed by PC<sub>H</sub> and PSW).

The stack can be located anywhere within the data memory space except the register bank area, therefore the stack depth is limited only by the free data memory size.

## 1.7.2 Stack Pointer (SP)

**TOSHIBA** 

The stack pointer (SP) is a 16-bit register containing the address of the next free locations on the stack.

The SP is post-decremented when a subroutine call or a push instruction is executed, or when an interrupt is accepted; and the SP is pre-incremented when a return or a pop instruction is executed. Figure 1-9 shows the stacking order.

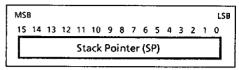

Figure 1-8. Stack Pointer

The SP is not initialized hardware-wise but requires initialization by an initialize routine (sets the highest stack address). [LD SP, mn], [LD SP, gg] and [LD gg, SP] are the SP access instructions (mn; 16-bit immediate data, gg; register pair).

Example 1: To initialize the SP

LD SP, 043FH

; SP ← 043F<sub>H</sub>

Example 2: To read the SP

LD HL, SP

; HL←SP

## 1.8 System Clock Controller

www.DataSheet4U.com

The system clock controller consists of a clock generator, a timing generator, and a stand-by controller.

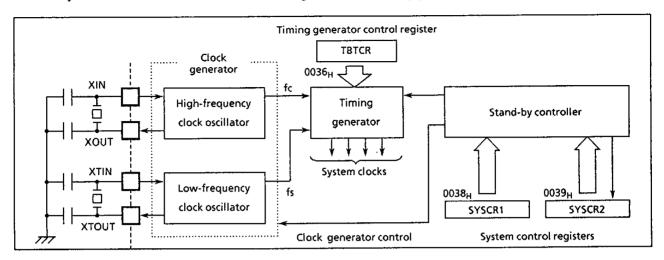

Figure 1-10. System Clock Controller

#### 1.8.1 Clock Generator

The clock generator generates the basic clock which provides the system clocks supplied to the CPU core and peripheral hardware. It contains two oscillation circuits: one for the high-frequency clock and one for the low-frequency clock. Power consumption can be reduced by switching of the system clock controller to low-power operation based on the low-frequency clock.

The high-frequency (fc) and low-frequency (fs) clocks can be easily obtained by connecting a resonator between the XIN / XOUT and XTIN / XTOUT pins, respectively. Clock input from an external oscillator is also possible. In this case, external clock is applied to the XIN / XTIN pin with the XOUT / XTOUT pin not connected. The 87CH37/K37/M37 are not provided an RC oscillation.

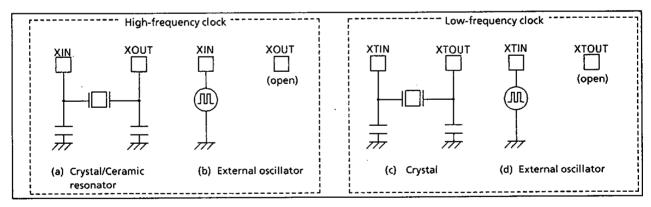

Figure 1-11. Examples of Resonator Connection

Note: Accurate Adjustment of the Oscillation Frequency:

Although hardware to externally and directly monitor the basic clock pulse is not provided, the oscillation frequency can be adjusted by making the program to output fixed frequency pulses to the port while disabling all interrupts and monitoring this pulse. With a system requiring adjustment of the oscillation frequency, the adjusting program must be created beforehand.

3-37-16

Example : To output the high-frequency oscillation frequency adjusting monitor pulse to P13

(DVO) pin.

SFCCHK: LD (P1CR), 00001000B; Configures port P13 as an output

SET (P1).3 ; P13 output latch  $\leftarrow$  1 LD (TBTCR), 11100000B; Enables divider output

JRS T,\$; Loops endless

#### 1.8.2 Timing Generator

The timing generator generates from the basic clock the various system clocks supplied to the CPU core and peripheral hardware. The timing generator provides the following functions:

- ① Generation of main system clock
- ② Generation of divider output (DVO) pulses
- 3 Generation of source clocks for time base timer
- Generation of source clocks for watchdog timer
- ⑤ Generation of internal source clocks for timer / counters TC1 TC4
- © Generation of warm-up clocks for releasing STOP mode
- Generation of a clock for releasing reset output

#### (1) Configuration of Timing Generator

The timing generator consists of a 21-stage divider with a divided-by-4 prescaler, a main system clock generator, and machine cycle counters. An input clock to the 7th stage of the divider depends on the operating mode and DV7CK (bit 4 in TBTCR) shown in Figure 1-12 as follows. During reset and at releasing STOP mode, the divider is cleared to "0", however, the prescaler is not cleared.

① In the single-clock mode
A divided-by-256 of high-frequency clock (fc/28) is input to the 7th stage of the divider.

clock to the 1st stage is stopped; output from the 1st to 6th stages is also stopped.

② In the dual-clock mode

During NORMAL2 or IDLE2 mode (SYSCK = 0), an input clock to the 7th stage of the divider can be selected either "fc/28" or "fs" with DV7CK.

During SLOW or SLEEP mode (SYSCK = 1), fs is automatically input to the 7th stage. To input

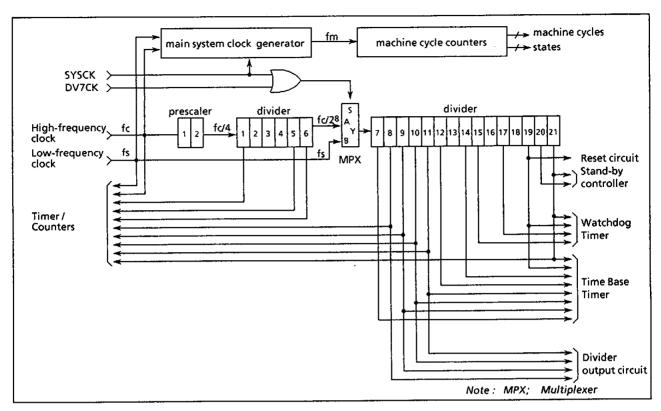

Figure 1-12. Configuration of Timing Generator

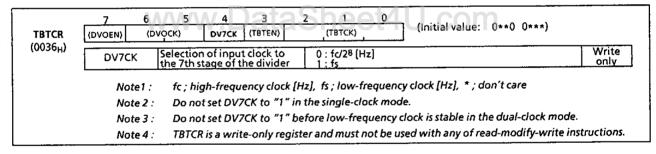

Figure 1-13. Timing Generator Control Register

#### (2) Machine Cycle

Instruction execution and peripheral hardware operation are synchronized with the main system clock. The minimum instruction execution unit is called a "machine cycle". There are a total of 10 different types of instructions for the TLCS-870 Series: ranging from 1-cycle instructions which require one machine cycle for execution to 10-cycle instructions which require 10 machine cycles for execution

A machine cycle consists of 4 states (S0 to S3), and each state consists of one main system clock.

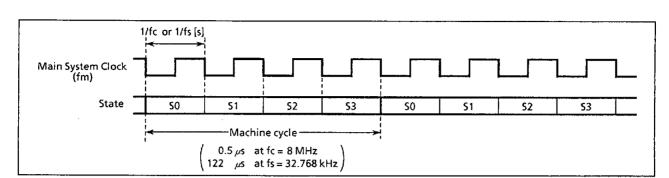

Figure 1-14. Machine Cycle

## 1.8.3 Stand-by Controller

The stand-by controller starts and stops the oscillation circuits for the high-frequency and low-frequency clocks, and switches the main system clock. There are two operating modes: single-clock and dual-clock. These modes are controlled by the system control registers (SYSCR1, SYSCR2).

Figure 1-15 shows the operating mode transition diagram and Figure 1-16 shows the system control registers. Either the single-clock or the dual-clock mode can be selected by an option during reset.

#### (1) Single-clock mode

Only the oscillation circuit for the high-frequency clock is used, and P21 (XTIN) and P22 (XTOUT) pins are used as input/output ports. In the single-clock mode, the machine cycle time is 4/fc [s] (0.5  $\mu$ s at fc = 8 MHz).

#### ① NORMAL1 mode

In this mode, both the CPU core and on-chip peripherals operate using the high-frequency clock. In the case where the single-clock mode has been selected as an option, the 87CH37/K37/M37 are placed in this mode after reset.

#### 2 IDLE1 mode

In this mode, the internal oscillation circuit remains active. The CPU and the watchdog timer are halted; however, on-chip peripherals remain active (operate using the high-frequency clock). IDLE1 mode is started by setting IDLE bit in the system control register 2 (SYSCR2), and IDLE1 mode is released to NORMAL1 mode by an interrupt request from on-chip peripherals or external interrupt inputs. When IMF (interrupt master enable flag) is "1" (interrupt enable), the execution will resume upon acceptance of the interrupt, and the operation will return to normal after the interrupt service is completed. When IMF is "0" (interrupt disable), the execution will resume with the instruction which follows IDLE mode start instruction.

## ③ STOP1 mode

In this mode, the internal oscillation circuit is turned off, causing all system operations to be halted. The internal status immediately prior to the halt is held with the lowest power consumption during this mode. The output status of all output ports can be set to either output hold or high-impedance under software control.

STOP1 mode is started by setting STOP bit in the system control register 1 (SYSCR1), and STOP1 mode is released by an input (either level-sensitive or edge-sensitive can be programmably selected) to the STOP pin. After the warming-up period is completed, the execution resumes with the next instruction which follows the STOP mode start instruction.

#### (2) Dual-clock mode

**TOSHIBA** 

Both high-frequency and low-frequency oscillation circuits are used in this mode. Pins P21 (XTIN) and P22 (XTOUT) cannot be used as input/output ports. The main system clock is obtained from the high-frequency clock in NORMAL2 and IDLE2 modes, and is obtained from the low-frequency clock in SLOW and SLEEP modes. The machine cycle time is 4/fc [s] (0.5  $\mu$ s at fc = 8 MHz) in NORMAL2 and IDLE2 modes, and 4/fs [s] (122  $\mu$ s at fs = 32.768 kHz) in SLOW and SLEEP modes. Note that the 87PM37 is placed in the single-clock mode during reset. To use the dual-clock mode, the low-frequency oscillator should be turned on by executing [SET (SYSCR2).XTEN] instruction.

#### ① NORMAL2 mode

In this mode, the CPU core operates using the high-frequency clock. On-chip peripherals operate using the high-frequency clock and / or low-frequency clock. In case that the dual-clock mode has been selected by an option, the 87CH37/K37/M37 are placed in this mode after reset.

#### ② SLOW mode

This mode can be used to reduce power-consumption by turning off oscillation of the high-frequency clock. The CPU core and on-chip peripherals operate using the low-frequency clock.

Switching back and forth between NORMAL2 and SLOW modes is performed by the system control register 2.

#### ③ IDLE2 mode

In this mode, the internal oscillation circuits remain active. The CPU and the watchdog timer are halted; however, on-chip peripherals remain active (operate using the high-frequency clock and / or the low-frequency clock). Starting and releasing of IDLE2 mode are the same as for IDLE1 mode, except that operation returns to NORMAL2 mode.

#### § SLEEP mode

In this mode, the internal oscillation circuit of the low-frequency clock remains active. The CPU, the watchdog timer, and the internal oscillation circuit of the high- frequency clock are halted; however, on-chip peripherals remain active (operate using the low-frequency clock). Starting and releasing of SLEEP mode is the same as for IDLE1 mode, except that operation returns to SLOW mode.

#### ⑤ STOP2 mode

As in STOP1 mode, all system operations are halted in this mode.

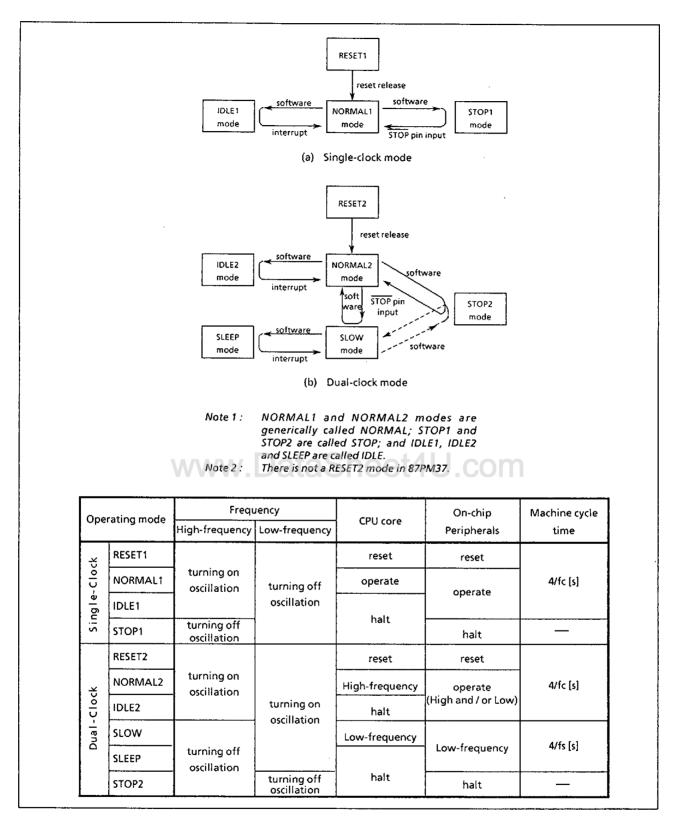

Figure 1-15. Operating Mode Transition Diagram

MAINTENANCE

Figure 1-16. System Control Registers

3-37-22

## 1.8.4 Operating Mode Control

#### (1) STOP mode (STOP1, STOP2)

STOP mode is controlled by the system control register 1 (SYSCR1) and the STOP pin input. The STOP pin is also used both as a port P20 and an INT5 (external interrupt input 5) pin. STOP mode is started by setting STOP (bit 7 in SYSCR1) to "1". During STOP mode, the following status is maintained.

- ① Oscillations are turned off, and all internal operations are halted.
- ② The data memory, registers (except DBR) and port output latches are all held in the status in effect before STOP mode was entered. The port output can be select either output hold or high-impedance by setting OUTEN (bit 4 in SYSCR1).
- ③ The divider of the timing generator is cleared to "0".
- The program counter holds the address of the instruction following the instruction which started the STOP mode.

STOP mode includes a level-sensitive release mode and an edge-sensitive release mode, either of which can be selected with RELM (bit 6 in SYSCR1).

#### a. Level-sensitive release mode (RELM = 1)

In this mode, STOP mode is released by setting the STOP pin high. This mode is used for capacitor back-up when the main power supply is cut off and long term battery back-up. When the STOP pin input is high, executing an instruction which starts the STOP mode will not place in STOP mode but instead will immediately start the release sequence (warm-up). Thus, to start STOP mode in the level-sensitive release mode, it is necessary for the program to first confirm that the STOP pin input is low. The following method can be used for confirmation:

Using an external interrupt input INT5 (INT5 is a falling edge-sensitive input).

Example : Starting STOP mode with an INT5 interrupt.

PINT5: TEST (P2). 0 ; To reject noise, the STOP mode does not start if

JRS F, SINT5 port P20 is at high

LD (SYSCR1), 01000000B ; Sets up the level-sensitive release mode.

SET (SYSCR1).7; Starts STOP mode

LDW (IL), 1110011101010111B;  $IL_{12, 11, 7, 5, 3} \leftarrow 0$  (Clears interrupt latches)

SINT5: RETI

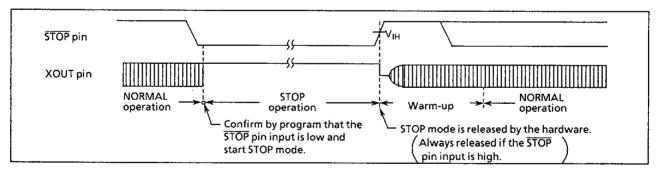

Figure 1-17. Level-sensitive Release Mode

Note1: After warming up is started, when STOP pin input is changed "L" level, STOP mode is not placed.

Note2: When changing to the level-sensitive release mode from the edge-sensitive release mode, the release mode is not switched until a rising edge of the STOP pin input is detected.

#### Edge-sensitive release mode (RELM = 0)

Εľ

In this mode, STOP mode is released by a rising edge of the STOP pin input. This is used in applications where a relatively short program is executed repeatedly at periodic intervals. This periodic signal (for example, a clock from a low-power consumption oscillator) is input to the STOP pin.

In the edge-sensitive release mode, STOP mode is started even when the STOP pin input is high.

Example : Starting STOP mode operation in the edge-sensitive release mode

LD (SYSCR1), 00000000B ; OUTEN  $\leftarrow$  0 (specifies high-impedance)  $\Rightarrow$  : IMF  $\leftarrow$  0 (disables interrupt service)

SET (SYSCR1). STOP ;STOP ← 1 (activates stop mode)

LDW (IL), 1110011101010111B ; IL12, 11, 7, 5, 3 ← 0 (clears interrupt latches)

; IMF ← 1 (enables interrupt service)

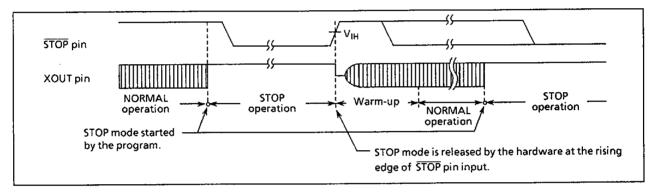

Figure 1-18. Edge-sensitive Release Mode

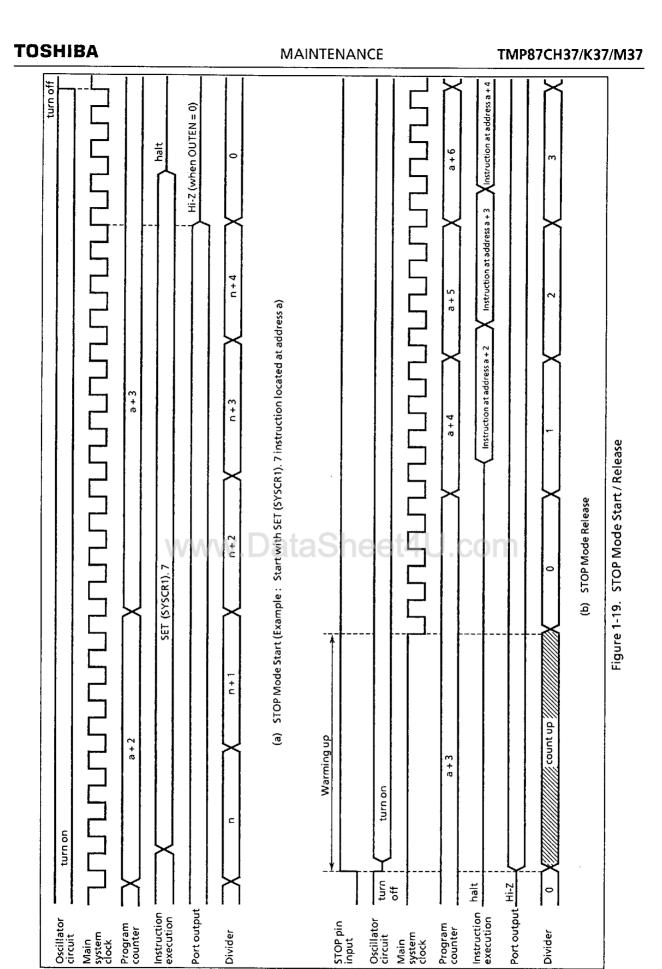

#### STOP mode is released by the following sequence:

- ① When returning to NORMAL2, both the high-frequency and low-frequency clock oscillators are turned on; when returning to SLOW mode, only the low-frequency clock oscillator is turned on. When returning to NORMAL1, only the high-frequency clock oscillator is turned on
- ② A warming-up period is inserted to allow oscillation time to stabilize. During warm-up, all internal operations remain halted. Two different warming-up times can be selected with WUT (bits 2 and 3 in SYSCR1) as determined by the resonator characteristics.
- When the warming-up time has elapsed, normal operation resumes with the instruction following the STOP mode start instruction (e.g. [SET (SYSCR1). 7]). The start is made after the divider of the timing generator is cleared to "0".

Table 1-1. Warming-up Time Example

Re	Return to NORMAL mode			Return to SLOW mode		
WUT	At fc = 4.194304 MHz	At fc=8MHz	WUT	At fs = 32.768 kHz		
3 × 2 <sup>19</sup> /fc [s] 2 <sup>19</sup> /fc	375 [ms] 125	196.6 [ms] 65.5	$3 \times 2^{13}/\text{fs}$ [s] $2^{13}/\text{fs}$	750 [ms] 250		

Note: The warming-up time is obtained by dividing the basic clock by the divider: therefore, the warming-up time may include a certain amount of error if there is any fluctuation of the oscillation frequency when STOP mode is released. Thus, the warming-up time must be considered an approximate value.

3-37-25

www.DataSheet4U.com

DataSheet4U.com www.DataSheet4U.com

STOP mode can also be released by setting the RESET pin low, which immediately performs the normal reset operation. 87CH37/CK37/M37 restarts NORMAL2 mode (NORMAL1 mode at 87PM37), even if setting is returning to SLOW mode.

Note: When STOP mode is released with a low hold voltage, the following cautions must be observed.

The power supply voltage must be at the operating voltage level before releasing STOP mode. The RESET pin input must also be high, rising together with the power supply voltage. In this case, if an external time constant circuit has been connected, the RESET pin input voltage will increase at a slower rate than the power supply voltage. At this time, there is a danger that a reset may occur if input voltage level of the RESET pin drops below the non-inverting high-level input voltage (hysteresis input).

#### (2) IDLE mode (IDLE1, IDLE2, SLEEP)

IDLE mode is controlled by the system control register 2 and maskable interrupts. The following status is maintained during IDLE mode.

- ① Operation of the CPU and watchdog timer is halted. On-chip peripherals continue to operate.
- The data memory, CPU registers and port output latches are all held in the status in effect before IDLE mode was entered.
- The program counter holds the address of the instruction following the instruction which started IDLE mode.

Example : Starting IDLE mode. SET (SYSCR2).4 ; IDLE←1

IDLE mode includes a normal release mode and an interrupt release mode. Selection is made with the interrupt master enable flag (IMF). Releasing the IDLE mode returns from IDLE1 to NORMAL1, from IDLE2 to NORMAL2, and from SLEEP to SLOW mode.

#### a. Normal release mode (IMF = "0")

IDLE mode is released by any interrupt source enabled by the individual interrupt enable flag (EF) or an external interrupt 0 (INTO pin) request. Execution resumes with the instruction following the IDLE mode start instruction (e.g. [SET

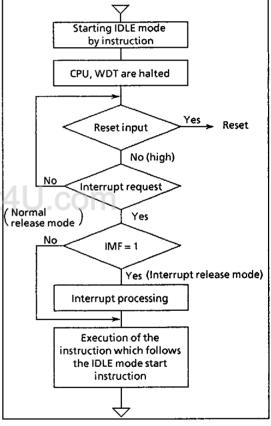

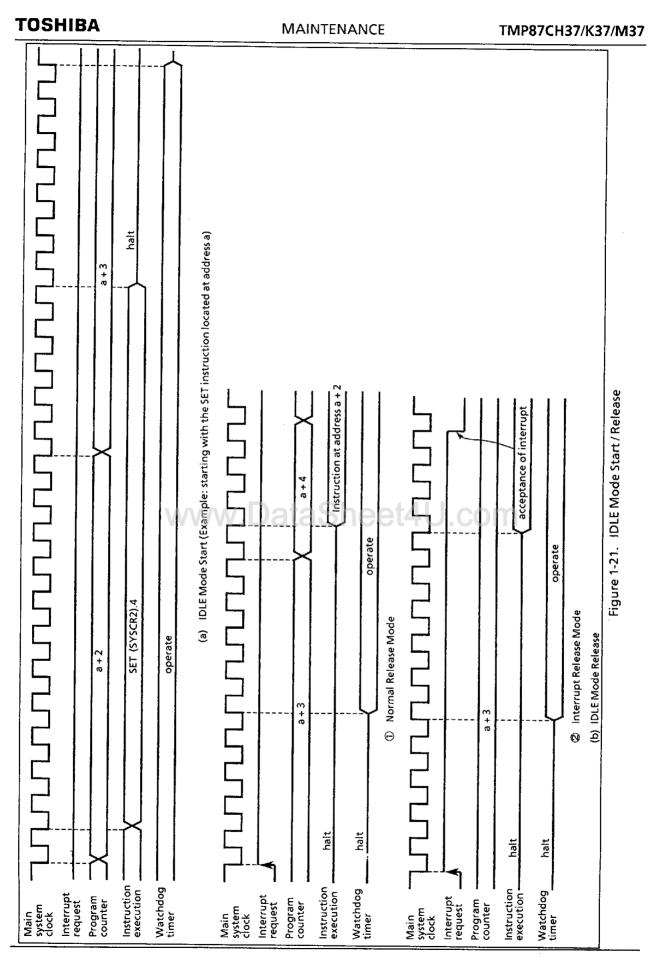

Figure 1-20. IDLE Mode

(SYSCR2).4]). Normally, IL (Interrupt Latch) of interrupt source to release IDLE mode must be cleared by load instructions.

## b. Interrupt release mode (IMF = "1")

IDLE mode is released and interrupt processing is started by any interrupt source enabled with the individual interrupt enable flag (EF) or an external interrupt 0 (INTO pin) request. After the interrupt is processed, the execution resumes from the instruction following the instruction which started IDLE mode.

3-37-27

www.DataSheet4U.com

DataSheet4U.com www.DataSheet4U.com

IDLE mode can also be released by setting the  $\overline{\text{RESET}}$  pin low, which immediately performs the reset operation. After reset, the 87CH37/K37/M37 are placed in NORMAL mode.

Note: When a watchdog timer interrupt is generated immediately before the IDLE mode is started, the watchdog timer interrupt will be processed but IDLE mode will not be started.

### (3) SLOW mode

SLOW mode is controlled by the system control register 2 and the timer / counter 2.

## a. Switching from NORMAL2 mode to SLOW mode

First, set SYSCK (bit 5 in SYSCR2) to switch the main system clock to the low-frequency clock. Next, clear XEN (bit 7 in SYSCR2) to turn off high-frequency oscillation.

When the low-frequency clock oscillation is unstable, wait until oscillation stabilizes before performing the above operations. The timer / counter 2 (TC2) can conveniently be used to confirm that low-frequency clock oscillation has stabilized.

Note: The high frequency clock can be continued oscillation in order to return to NORMAL2 mode from SLOW mode quickly. Always turn off oscillation of high frequency clock when switching from SLOW mode to STOP mode.

Example 1: Switching from NORMAL2 mode to SLOW mode.

SET (SYSCR2). 5 ; SYSCK←1 (Switches the main system clock to the

low-frequency clock)

CLR (SYSCR2).7; XEN←0 (turns off high-frequency oscillation)

Example 2: Switching to SLOW mode after low-frequency clock oscillation has stabilized.

SET (SYSCR2).5; SYSCK←1

CLR (SYSCR2).7 ; XEN←0

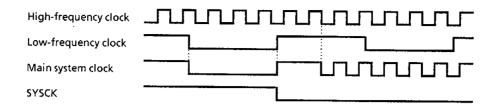

RETI

VINTTC2: DW PINTTC2 ; INTTC2 vector table

#### b. Switching from SLOW mode to NORMAL2 mode

First, set XEN (bit 7 in SYSCR2) to turn on the high-frequency oscillation. When time for stabilization (warm-up) has been taken by the timer / counter 2 (TC2), clear SYSCK (bit 5 in SYSCR2) to switch the main system clock to the high-frequency clock.

Note1: After SYSCK is cleared, executing instructions is continued by low-frequency clock while low-frequency clock and high-frequency clock synchronize each other.

Note2: SLOW mode can also be released by setting the RESET pin low, which immediately performs the reset operation. After reset, the 87CH37/CK37/M37 are placed in NORMAL2 mode. (The 87PM37 is placed in NORMAL1 mode.)

Example : Switching from SLOW mode to NORMAL2 mode (fc = 8 MHz, warming-up time is

about 7.9 ms).

SET (SYSCR2).7; XEN←1 (turns on high-frequency oscillation)

LD (TC2CR), 10H ; Sets TC2 mode

## 1.9 Interrupt Controller

**TOSHIBA** 

The 87CH37/K37/M37 has a total of 15 interrupt sources: 6 externals and 9 internals. Nested interrupt control with priorities is also possible. Two of the internal sources are pseudo non-maskable interrupts; the remainder are all maskable interrupts.

Interrupt latches (IL) that hold the interrupt requests are provided for interrupt sources. Each interrupt vector is independent.

The interrupt latch is set to "1" when an interrupt request is generated and requests the CPU to accept the interrupt. The acceptance of maskable interrupts can be selectively enabled and disabled by the program using the interrupt master enable flag (IMF) and the individual interrupt enable flags (EF). When two or more interrupts are generated simultaneously, the interrupt is accepted in the highest priority order as determined by the hardware. Figure 1-23 shows the interrupt controller.

		Interrupt Source	Enable Condition	Interrupt Latch	Vector Table Address	Priority
Internal/ External	(Reset)		Non-Maskable		FFFE <sub>H</sub>	High 0
Internal	INTSW	(Software interrupt)	Pseudo	_	FFFCH	1
Internal	INTWDT	(Watchdog Timer interrupt)	non-maskable	IL <sub>2</sub>	FFFA <sub>H</sub>	2
External	INT0	(External interrupt 0)	IMF = 1, INTOEN = 1	IL <sub>3</sub>	FFF8 <sub>H</sub>	3

## (1) Interrupt Latches (IL 15 to 2)

Interrupt latches are provided for each source, except for a software interrupt. The latch is set to "1" when an interrupt request is generated, and requests the CPU to accept the interrupt. The latch is cleared to "0" just after the interrupt is accepted. All interrupt latches are initialized to "0" during reset. They must be cleared to "0" by software before enabling interrupt.

The interrupt latches are assigned to addresses  $003C_H$  and  $003D_H$  in the SFR. Each latch can be cleared to "0" individually by an instruction; however, the read-modify-write instruction such as bit manipulation or operation instructions cannot be used. Thus, interrupt requests can be cancelled and initialized by the program. Don't clear the  $IL_2$  for a watchdog timer interrupt to "0". Note that interrupt latches cannot be set to "1" by any instruction.

The contents of interrupt latches can be read out by an instruction. Therefore, testing interrupt requests by software is possible.

JR F, SSET

## (2) Interrupt Enable Register (EIR)

The interrupt enable registers (EIR) enable and disable the acceptance of interrupts except for the pseudo non-maskable interrupts (software and watchdog timer interrupts). Pseudo non-maskable interrupts are accepted regardless of the contents of the EIR; however, the pseudo non-maskable interrupts cannot be nested more than once at the same time. For example, the watchdog timer interrupt is not accepted during the software interrupt service.

The EIR consists of an interrupt master enable flag (IMF) and individual interrupt enable flags (EF). These registers are assigned to addresses 003A<sub>H</sub> and 003B<sub>H</sub> in the SFR, and can be read and written by an instruction (including read-modify-write instructions such as bit manipulation instructions).

#### ① Interrupt Master enable Flag (IMF)

The interrupt master enable flag (IMF) enables and disables the acceptance of all interrupts, except for pseudo non-maskable interrupts. Clearing this flag to "0" disables the acceptance of all maskable interrupts. Setting to "1" enables the acceptance of interrupts. When an interrupt is accepted, this flag is cleared to "0" to temporarily disable the acceptance of maskable interrupts. After execution of the interrupt service program, this flag is set to "1" by the maskable interrupt return instruction [RETI] to again enable the acceptance of interrupts. If an interrupt request has already been occurred, interrupt service starts immediately after execution of the [RETI] instruction.

Pseudo non-maskable interrupts are returned by the [RETN] instruction. In this case, the IMF is set to "1" only when pseudo non-maskable interrupt service is started with interrupt acceptance enabled (IMF = 1). Note that the IMF remains "0" when cleared by the interrupt service program.

The IMF is assigned to bit 0 at address  $003A_H$  in the SFR, and can be read and written by an instruction. The IMF is normally set and cleared by the [EI] and [DI] instructions, and the IMF is initialized to "0" during reset.

#### ② Individual interrupt Enable Flags (EF<sub>15</sub> to EF<sub>4</sub>)

These flags enable and disable the acceptance of individual maskable interrupts, except for an external interrupt 0. Setting the corresponding bit of an individual interrupt enable flag to "1" enables acceptance of an interrupt, setting the bit to "0" disables acceptance.

Example 1: Sets EF for individual interrupt enable, and sets IMF to "1".

LDW (EIR), 1110100010100001B ;  $EF_{15}$  to  $EF_{13}$ ,  $EF_{11}$ ,  $EF_{7}$ ,  $EF_{5}$ ,  $IMF \leftarrow 1$ 

Example 2: Sets an individual interrupt enable flag to "1".

SET (EIRH).4 ; EF<sub>12</sub>←1

Figure 1-24. Interrupt Latch (IL) and Interrupt Enable Register (EIR)

### 1.9.1 Interrupt Sequence

An interrupt request is held until the interrupt is accepted or the interrupt latch is cleared to "0" by a reset or an instruction. Interrupt acceptance sequence requires 8 machine cycles (4  $\mu$ s at fc = 8 MHz in NORMAL mode) after the completion of the current instruction execution. The interrupt service task terminates upon execution of an interrupt return instruction [RETI] (for maskable interrupts) or [RETN] (for pseudo non-maskable interrupts).

## (1) Interrupt acceptance processing is as follows:

- ① The interrupt master enable flag (IMF) is cleared to "0" to temporarily disable the acceptance of any following maskable interrupts. When a non-maskable interrupt is accepted, the acceptance of any following interrupts is temporarily disabled.
- ② The interrupt latch (IL) for the interrupt source accepted is cleared to "0".
- ③ The contents of the program counter (return address) and the program status word are saved (pushed) onto the stack. The stack pointer is decremented 3 times.
- The entry address of the interrupt service program is read from the vector table address, and the entry address is loaded to the program counter.
- ⑤ The instruction stored at the entry address of the interrupt service program is executed.

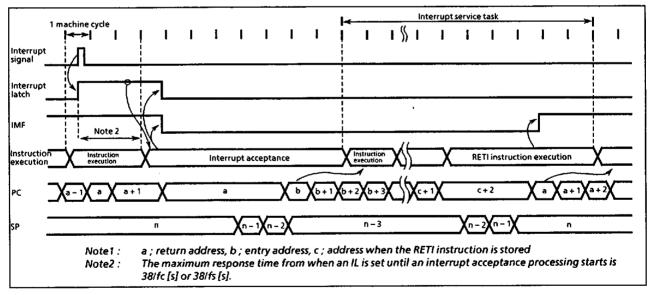

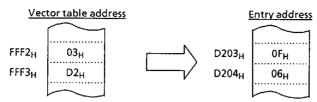

Figure 1-25. Timing Chart of Interrupt Acceptance and Interrupt Return Instruction

Example: Correspondence between vector table address for INTTBT and the entry address of the interrupt service program.

A maskable interrupt is not accepted until the IMF is set to "1" even if a maskable interrupt of higher priority than that of the current interrupt being serviced.

When nested interrupt service is necessary, the IMF is set to "1" in the interrupt service program. In this case, acceptable interrupt sources are selectively enabled by the individual interrupt enable flags. However, an acceptance of external interrupt 0 cannot be disabled by the EF; therefore, if disablement is necessary, either the external interrupt function of the INTO pin must be disabled with INTOEN in the external interrupt control register (EINTCR) or interrupt processing must be avoided by the program.

Example 1: Disables an external interrupt 0 using INTOEN:

(EINTCR), 000000008; INT0EN←0

Example 2 : Disables the processing of external interrupt 0 under the software control (using bit

0 at address 00FO<sub>H</sub> as the interrupt processing disable switch):

PINTO: TEST (00F0H).0 ; Returns without interrupt processing if  $(00F0_H)_0 = 1$

VINTO: DW

#### (2) Saving / Restoring General Purpose Registers

During interrupt acceptance processing, the program counter and the program status word are automatically saved on the stack, but not the accumulator and other registers. These registers are saved by the program if necessary. Also, when nesting multiple interrupt services, it is necessary to avoid using the same data memory area for saving registers.

The following method is used to save / restore the general-purpose registers:

① General-purpose register save / restore by register bank changeover: General-purpose registers can be saved at high-speed by switching to a register bank that is not in use. Normally, bank 0 is used for the main task and banks 1 to 15 are assigned to interrupt service tasks. To increase the efficiency of data memory utilization, the same bank is assigned for interrupt sources which are not nested.

The switched bank is automatically restored by executing an interrupt return instruction [RETI] or [RETN]. Therefore, it is not necessary for a program to save the RBS.

Example: Register Bank Changeover

PINTxx : LD RBS, n ; Switches to bank n (1  $\mu$ s at 8 MHz) interrupt processing

: Restores bank and Returns

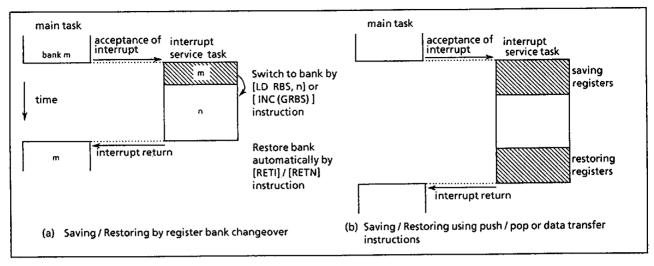

Figure 1-26. Saving / Restoring General-purpose Registers

© General-purpose register save/restore using push and pop instructions:

To save only a specific register, and when the same interrupt source occurs more than once, the general-purpose registers can be saved / restored using push/pop instructions.

Example: Register save using push and pop instructions PUSH WA ; Save WA register pair PINTxx: Save HL register pair PUSH ΗL interrupt processing Restore HL register pair POP HL Restore WA register pair POP WA **RETI** Return Address (example) 0438<sub>H</sub> 0439 Н 043A 043B Α 043C W PCL 043D PCL РСН PCH 043E  $PC_{H}$ 043F PSW PSW PSW At execution of an At acceptance At execution At execution interrupt return of an interrupt of a push of a pop instruction instruction instruction

③ General-purpose registers save / restore using data transfer instruction: Data transfer instructions can be used to save only a specific general-purpose register during processing of a single interrupt.

Example: Saving / restoring a register using data transfer instructions

PINTxx: LD (GSAVA), A ; Save A register

interrupt processing

LD A, (GSAVA) ; Restore A register

RETI ; Return

**MAINTENANCE** 

TMP87CH37/K37/M37

(3) The interrupt return instructions [RETI] / [RETN] perform the following operations.

	[RETI] Maskable interrupt return	[RETN] Non-maskable interrupt return				
1	The contents of the program counter and the program status word are restored from the stack.	1	The contents of the program counter and program status word are restored from the stack.			
2	The stack pointer is incremented 3 times.	2	The stack pointer is incremented 3 times.			
3	The interrupt master enable flag is set to "1".	3	The interrupt master enable flag is set to "1" only when a non-maskable interrupt is accepted in interrupt enable status. However, the interrupt master enable flag remains at "0" when so clear by an interrupt service program.			

Interrupt requests are sampled during the final cycle of the instruction being executed. Thus, the next interrupt can be accepted immediately after the interrupt return instruction is executed.

Note: When the interrupt processing time is longer than the interrupt request generation time, the interrupt service task is performed but not the main task.

#### 1.9.2 Software Interrupt (INTSW)

www.DataSheet4U.com

**TOSHIBA** 

Executing the [SWI] instruction generates a software interrupt and immediately starts interrupt processing (INTSW is highest prioritized interrupt). However, if processing of a non-maskable interrupt is already underway, executing the SWI instruction will not generate a software interrupt but will result in the same operation as the [NOP] instruction. Thus, the [SWI] instruction behaves like the [NOP] instruction.

Note: At the development tool, if processing of a non-maskable interrupt is already underway, executing the SWI instruction will generate a software interrupt as a soft ware brake.

Use the [SWI] instruction only for detection of the address error or for debugging.

### ① Address Error Detection

 $FF_H$  is read if for some cause such as noise the CPU attempts to fetch an instruction from a non-existent memory address. Code  $FF_H$  is the SWI instruction, so a software interrupt is generated and an address error is detected. The address error detection range can be further expanded by writing  $FF_H$  to unused areas of the program memory. The address trap reset is generated in case that an instruction is fetched from RAM or SFR areas.

Note: The fetch data from addresses 7F80<sub>H</sub> to 7FFF<sub>H</sub> (test ROM area) is not "FF<sub>H</sub>".

#### ② Debugging

Debugging efficiency can be increased by placing the SWI instruction at the software break point setting address.

#### 1.9.3 External Interrupts

The 87CH37/K37/M37 each have six external interrupt inputs (INTO, INT1, INT2, INT3, INT4, and INT5). Four of these are equipped with digital noise rejection circuits (pulse inputs of less than a certain time are eliminated as noise). Edge selection is also possible with INT1, INT2, INT3 and INT4.

The INTO / P10 pin can be configured as either an external interrupt input pin or an input/output port, and is configured as an input port during reset.

Edge selection, noise rejection control except INT3 pin input and  $\overline{\text{INT0}}$  / P10 pin function selection are performed by the external interrupt control register (EINTCR). Edge selecting and noise rejection control for INT3 pin input are preformed by the Remote control signal preprocessor control registers. (refer to the section of the Remote control signal preprocessor.) When INT0EN = 0, the IL3 will not be set even if the falling edge of  $\overline{\text{INT0}}$  pin input is detected.

Table 1-3. External Interrupts

Source	Pin	Secondary function pin	Enable conditions	Edge	Digital noise rejection
INTO	INTO	P10	IMF = 1, INT0EN = 1	falling edge	— (hysteresis input)
INT1	INT1	P11	IMF · EF <sub>5</sub> = 1	falling edge or	Pulses of less than 15/fc or 63/fc [s] are eliminated as noise. Pulses equal to or more than 48/fc [s] or 192/fc [s] are regarded as signals.
INT2	INT2	P12/TC1	IMF · EF <sub>7</sub> = 1	rising edge	Pulses of less than 7/fc [s] are eliminated as noise. Pulses equal to or more than 24/fc [s] are regarded as signals.
INT3	INT3	P30/RXIN	!MF · EF <sub>11</sub> = 1	falling edge, rising edge or falling / rising edge	Refer to the section of the Remote control preprocessor
INT4	INT4	P32	IMF • EF <sub>12</sub> = 1	falling edge or rising edge	Pulses of less than 7/fc [s] are eliminated as noise. Pulses equal to or more than 24/fc [s] are regarded as signals.
INT5	ĪNT5	P20/STOP	IMF • EF <sub>15</sub> = 1	falling edge	

Note 1: The noise rejection function is turned off in the SLOW and SLEEP modes. Also, the noise reject times are not constant for pulses input while transiting between operating modes (NORMAL2↔SLOW)

Note 2: The noise rejection function is also affected for timer/counter input (TC1 pin).

Note 3: The pulse width (both "H" and "L" level) for input to the  $\overline{\text{INTO}}$  and  $\overline{\text{INTS}}$  pins must be over 1 machine cycle.

Note 4: If a noiseless signal is input to the external interrupt pin in the NORMAL 1/2 or IDLE 1/2 mode, the maximum time from the edge of input signal until the IL is set is as follows:

① INT1 pin

49/fc [s] (INT1NC = 1), 193/fc [s] (INT1NC = 0)

INT2,INT4 pins

25/fc [s]

③ INT3 pin

Refer to the section of the Remote control preprocessor.

Note 5: When high-impedance is specified for port output in stop mode, port input is forcibly fixed to low level internally. Thus, interrupt latches of external interrupt inputs except P20 (INT5/STOP) which are also used as ports may be set to "1". To specify high-impedance for port output in stop mode, first disable interrupt service (IMF=0), activate stop mode. After releasing stop mode, clear interrupt latches using load instruction, then, enable interrupt service.

#### **MAINTENANCE**

**MAINTENANCE** 

## 1.10 Watchdog Timer (WDT)

**TOSHIBA** 

www.DataSheet4U.com

The watchdog timer rapidly detects the CPU malfunction such as endless looping caused by noise or the like, and resumes the CPU to the normal state.

TMP87CH37/K37/M37

The watchdog timer signal for detecting malfunction can be selected either a reset output or a non-maskable interrupt request. However, selection is possible only once after reset. At first the reset output is selected.

When the watchdog timer is not being used for malfunction detection, it can be used as a timer to generate an interrupt at fixed intervals.

1.10.1 Watchdog Timer Configuration

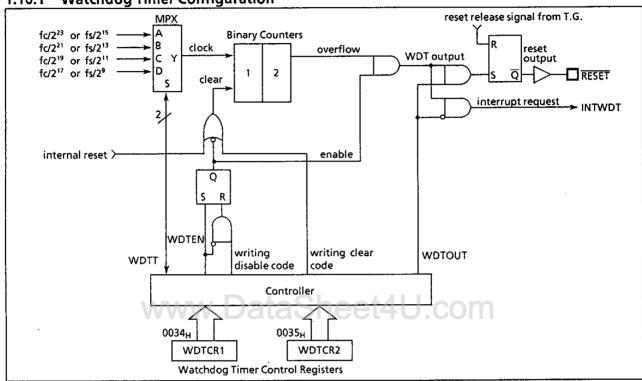

Figure 1-28. Watchdog Timer Configuration

#### 1.10.2 Watchdog Timer Control

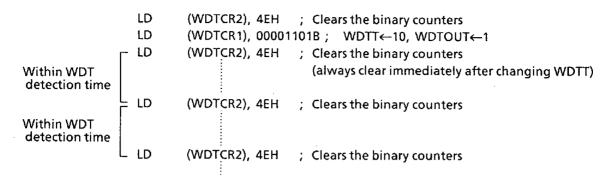

Figure 1-29 shows the watchdog timer control registers (WDTCR1, WDTCR2). The watchdog timer is automatically enabled after reset.

- (1) Malfunction detection methods using the watchdog timer
  - The CPU malfunction is detected as follows.
    - ① Setting the detection time, selecting output, and clearing the binary counter.
    - ② Repeatedly clearing the binary counter within the setting detection time.

If the CPU malfunction occurs for any cause, the watchdog timer output will become active at the rising of an overflow from the binary counters unless the binary counters are cleared. At this time, when WDTOUT = 1, a reset is generated, which drives the  $\overline{RESET}$  pin low to reset the internal hardware and the external circuits. When WDTOUT = 0, a watchdog timer interrupt (INTWDT) is generated.

The watchdog timer temporarily stops counting in the STOP mode including warm-up or IDLE mode, and automatically restarts (continues counting) when the STOP/IDLE mode is released.

Example: Sets the watchdog timer detection time to 221/fc [s] and resets the CPU malfunction.

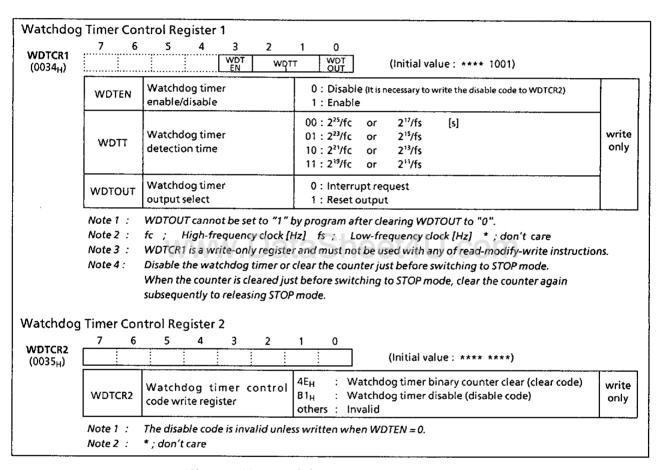

Figure 1-29. Watchdog Timer Control Registers

Table 1-4. Watchdog Timer Detection Time

	Operating mode	Detection time			
NORMAL1	NORMAL2	SLOW	At fc = 8 MHz	At fs = 32.768 kHz	
2 <sup>25</sup> /fc [s]	2 <sup>25</sup> /fc, 2 <sup>17</sup> /fs	2 <sup>17</sup> /fs	4.194 s	4 s	
2 <sup>23</sup> /fc	2 <sup>23</sup> /fc, 2 <sup>15</sup> /fs	2 <sup>15</sup> /fs	1.048 s	1 s	
2 <sup>21</sup> /fc	2 <sup>21</sup> /fc, 2 <sup>13</sup> /fs		262.1 ms	250 ms	
2 <sup>19</sup> /fc	2 <sup>19</sup> /fc, 2 <sup>11</sup> /fs		65.5 ms	62.5 ms	

3-37-41

#### (2) Watchdog Timer Enable

**TOSHIBA** 

The watchdog timer is enabled by setting WDTEN (bit 3 in WDTCR1) to "1". WDTEN is initialized to "1" during reset, so the watchdog timer operates immediately after reset is released.

Example: Enables watchdog timer

LD (WDTCR1), 00001000B; WDTEN←1

#### (3) Watchdog Timer Disable

The watchdog timer is disabled by writing the disable code (81<sub>H</sub>) to WDTCR2 after clearing WDTEN (bit 3 in WDTCR1) to "0". The watchdog timer is not disabled if this procedure is reversed and the disable code is written to WDTCR2 before WDTEN is cleared to "0". The watchdog timer is halted temporarily in STOP mode (including warm-up) and IDLE mode, and restarts automatically after STOP or IDLE mode is released.

During disabling the watchdog timer, the binary counters are cleared to "0".

Example : Disables watchdog timer

LDW (WDTCR1), 0B101H; WDTEN←0, WDTCR2←disable code

## 1.10.3 Watchdog Timer Interrupt (INTWDT)

This is a pseudo non-maskable interrupt which can be accepted regardless of the contents of the EIR. If a watchdog timer interrupt or a software interrupt is already accepted, however, the new watchdog timer interrupt waits until the previous non-maskable interrupt processing is completed (the end of the [RETN] instruction execution).

The stack pointer (SP) should be initialized before using the watchdog timer output as an interrupt source with WDTOUT.

Example: Watchdog timer interrupt setting up.

LD SP, 043FH Signal Sets the stack pointer

LD (WDTCR1), 00001000B ; WDTOUT←0

#### 1.10.4 Watchdog Timer Reset

If the watchdog timer output becomes active, a reset is generated, which drives the  $\overline{\text{RESET}}$  pin (sink open drain output with pull-up registor) low to reset the internal hardware and the external circuits. The reset output time is  $2^{20}$ /fc [s] (131 ms at fc = 8 MHz). The high-frequency clock oscillator also turns on when a watchdog timer reset is generated in SLOW mode.

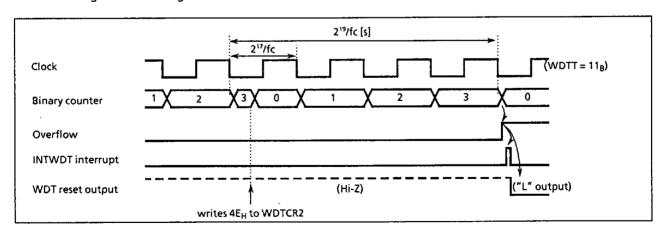

Figure 1-30. Watchdog Timer Interrupt / Reset

#### 1.11 Reset Circuit

The TLCS-870 series has four types of reset generation procedures: an external reset input, an address-trap-reset, a watchdog timer reset and a system-clock-reset. Table 1-5 shows on-chip hardware initialization by reset action.

The internal source reset circuit (watchdog timer reset, address trap reset, and system clock reset) is not initialized when power is turned on. Thus, output from the RESET pin may go low (2<sup>20</sup>/fc [s] 131 ms at 8 MHz) when power is turned on.

Table 1-5. Initializing Internal Status by Reset Action

On-chip Hardware		Initial Value	On-chip Hardware	Initial Value	
Program counter	(PC)	(FFFF <sub>H</sub> ) · (FFFE <sub>H</sub> )	Divider of Timing generator	0	
Register bank selector	(RBS)	0			
Jump status flag	(JF)	1	Watchdog timer	Enable	
Interrupt master enable flag	(IMF)	0	Output latches of I/O ports	Refer to I/O port	
Interrupt individual enable flags		0		Refer to each of	
Interrupt latches	(IL)	0	Control registers	control register	

#### 1.11.1 External Reset Input

When the RESET pin is held at low for at least 3 machine cycles (12/fc [s]) with the power supply voltage within the operating voltage range and oscillation stable, a reset is applied and the internal state is initialized.

When the RESET pin input goes high, the reset operation is released and the program execution starts at the vector address stored at addresses FFFE<sub>H</sub> to FFFF<sub>H</sub>.

The RESET pin contains a Schmitt trigger (hysteresis) with an internal pull-up resistor. A simple power-on-reset can be applied by connecting an external capacitor and a diode.

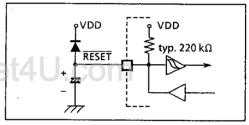

Figure 1-31. Simple Power-on-Reset Circuitry

#### 1.11.2 Address-Trap-Reset

If the CPU malfunction occurs and an attempt is made to fetch an instruction from the RAM or the SFR area, an address-trap-reset will be generated. Then, the  $\overline{RESET}$  pin output will go low. The reset time is  $2^{20}$ /fc [s] (131 ms at 8 MHz).

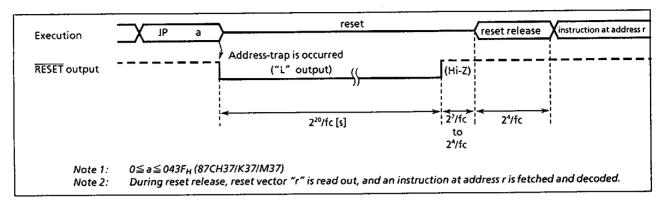

Figure 1-32. Address-Trap-Reset

## 1.11.3 Watchdog Timer Reset

Refer to Section "1.10 Watchdog Timer".

## 1.11.4 System-Clock-Reset

Clearing both XEN and XTEN (bits 7 and 6 in SYSCR2) to "0" stops both high-frequency and low-frequency oscillation, and causes the MCU to deadlock. This can be prevented by automatically generating a reset signal whenever XEN = XTEN = 0 is detected to continue the oscillation. Then, the RESET pin output goes low from high-impedance. The reset time is 2<sup>20</sup>/fc [s] (131 ms at 8 MHz).

## 2. ON-CHIP PERIPHERALS FUNCTIONS

# 2.1 Special Function Registers (SFR) and Data Buffer Registers (DBR)

The TLCS-870 Series uses the memory mapped I/O system, and all peripheral control and data transfers are performed through the special function registers (SFR) and data buffer registers (DBR). The SFR are mapped to addresses 0000<sub>H</sub> to 003F<sub>H</sub>, and the DBR to addresses 0F80<sub>H</sub> to 0FFF<sub>H</sub>. Figure 2-1 shows the 87CH37/K37/M37 SFRs and DBRs.

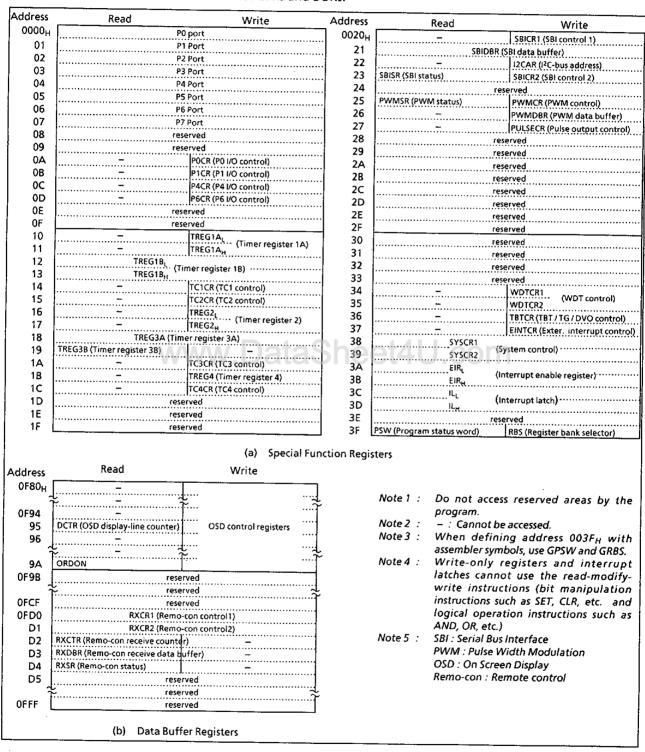

Figure 2-1. SFR & DBR

3-37-45

#### 2.2 I/O Ports

www.DataSheet4U.com

The 87CH37/K37/M37 each have 8 parallel input/output ports (56 pins) each as follows:

	Primary Function	Secondary Functions
Port P0	8-bit I/O port	_
Port P1	8-bit I/O port	external interrupt input, timer / counter input / output, and divider output
Port P2	3-bit I/O port	low-frequency resonator connections, external interrupt input, and STOP mode release signal input
Port P3	8-bit I/O port	external interrupt input, remote control signal input, timer/counter input, and serial bus interface input/output
Port P4	8-bit I/O port	pulse width modulation output
Port P5	8-bit I/O port	pulse width modulation output, pulse output, and comparator input
Port P6	8-bit I/O port	R, G, B and Y/BL output from OSD circuitry
Port P7	5-bit I/O port	horizontal synchronous pulse input and vertical synchronous pulse input to OSD circuitry

Each output port contains a latch, which holds the output data. All input ports do not have latches, so the external input data should either be held externally until read or reading should be performed several times before processing. Figure 2-2 shows input/output timing examples.

External data is read from an I/O port in the S1 state of the read cycle during execution of the read instruction. This timing can not be recognized from outside, so that transient input such as chattering must be processed by the program.

Output data changes in the S2 state of the write cycle during execution of the instruction which writes to an I/O port.

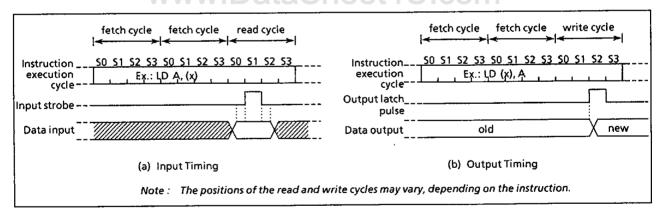

Figure 2-2. Input/Output Timing (Example)

When reading an I/O port except programmable I/O ports, whether the pin input data or the output latch contents are read depends on the instructions, as shown below:

- (1) Instructions that read the output latch contents
  - ① XCH r, (src)
- ⑤ LD
- (pp) . b, CF
- ② CLR/SET/CPL (src).b
- © ADD/ADDC/SUB/SUBB/AND/OR/XOR (src), n
- ③ CLR/SET/CPL (pp).g
- (src) side of ADD / ADDC / SUB / SUBB / AND / OR / XOR (src), (HL)
- 4 LD (src).b, CF

www.DataSheet4U.com

3-37-46

- (2) Instructions that read the pin input data
  - ① Instructions other than the above (1)
  - ② (HL) side of ADD / ADDC / SUB / SUBB / AND / OR / XOR (src), (HL)

#### 2.2.1 Port P0 (P07 to P00)

Port P0 is an 8-bit general-purpose input/output port which can be configured as either an input or an output in one-bit unit under software control. Input / output mode is specified by the corresponding bit in the port P0 input / output control register (POCR). Port P0 is configured as an input if its corresponding POCR bit is cleared to "0", and as an output if its corresponding POCR bit is set to "1".

During reset, POCR is initialized to "0", which configures port PO as input. The PO output latches are also initialized to "0". Data is written into the output latch regardless of the POCR contents. Therefore initial output data should be written into the output latch before setting POCR.

Note: Input mode port is read the state of input pin.

When input / output mode is used to mixed, the contents of input mode port may be changed by executing bit manipulation instructions.

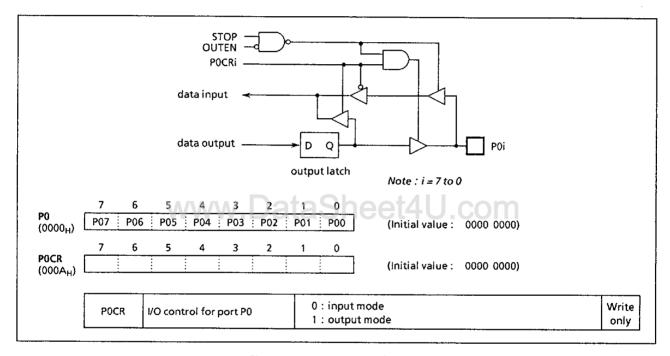

Figure 2-3. Port P0 and P0CR

Example : Setting the upper 4 bits of port P0 as an input port and the lower 4 bits as an output

port (Initial output data are 1010<sub>B</sub>).

LD (P0), 00001010B ; Sets initial data to P0 output latches

LD (POCR), 00001111B; Sets the port P0 input / output mode

## 2.2.2 Port P1 (P17 to P10)

Port P1 is an 8-bit input / output port which can be configured as an input or an output in one-bit unit under software control. Input / output mode is specified by the corresponding bit in the port P1 input / output control register (P1CR). Port P1 is configured as an input if its corresponding P1CR bit is cleared to "0", and as an output if its corresponding P1CR bit is set to "1". During reset, P1CR is initialized to "0", which configures port P1 as an input. The P1 output latches are also initialized to "0".

Data is written into the output latch regardless of the P1CR contents. Therfore initial output data should be written into the output latch before setting P1CR. Port P1 is also used as an external interrupt input, a timer/counter input, and a divider output. When used as a secondary function pin, the input pins should be set to the input mode, and the output pins should be set to the output mode and beforehand the output latch should be set to "1".

It is recommended that pins P11 and P12 should be used as external interrupt inputs, timer / counter input, or input ports. The interrupt latch is set on the rising or falling edge of the output when used as output ports.

Pin P10 (INTO) can be configured as either an I/O port or an external interrupt input with INTOEN (bit 6 in EINTCR). During reset, pin P10 (INTO) is configured as an input port P10.

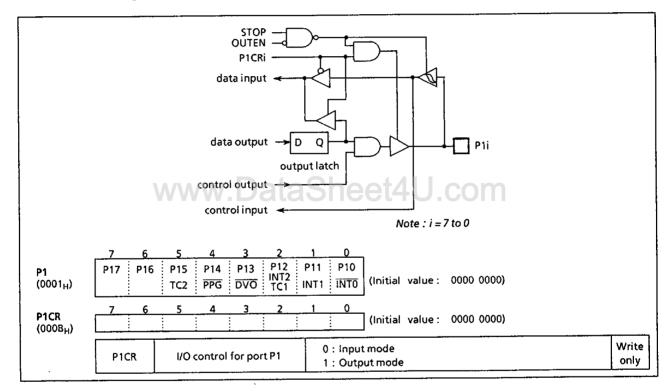

Figure 2-4. Port P1 and P1CR

Example: Sets P17, P16 and P14 as output ports, P13 and P11 as input ports, and the others as

function pins. Internal output data is "1" for the P17 and P14 pins, and "0" for the

P16 pin.

Note: Input mode port is read the state of input pin.

When input / output mode is used to mixed, the contents of input mode port may be changed by

executing bit manipulation instructions.

3-37-48

## 2.2.3 Port P2 (P22 to P20)

**TOSHIBA** 

Port P2 is a 3-bit input/output port. It is also used as an external interrupt input, a STOP mode release signal input, and as low-frequency crystal connection pins. When used as an input port, or a secondary function pin, the output latch should be set to "1". During reset, the output latches are initialized to "1".

A low-frequency crystal (32.768 kHz) is connected to pins P21 (XTIN) and P22 (XTOUT) in the dual-clock mode. In the single-clock mode, pins P21 and P22 can be used as normal input/output ports.

It is recommended that pin P20 should be used as an external interrupt input, a STOP mode release signal input, or an input port. If used as an output port, the interrupt latch is set on the falling edge of the P20 output pulse. When a read instruction for port P2 is executed, bits 7 to 3 in P2 are read in as undefined data.

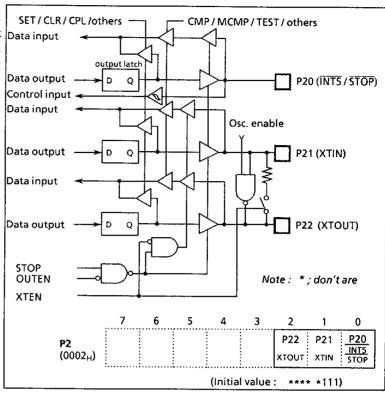

Figure 2-5. Port P2

## 2.2.4 Port P3 (P37 to P30)

Port P3 is an 8-bit input / output port, and is also used as serial bus interface input / output, an exrernal interrupt input a timer / counter input, and Remote-control signal input. When used as an input port or a secondary function pin, the output latch should be set to "1". The output latches are initialized to "1" during reset.

Example 1: Outputs an immediate data 5A<sub>H</sub> to port P3.

LD (P3), 5AH ; P3←5AH

Example 2: Inverts the output of the lower 4bits (P33 to P30) in port P3.

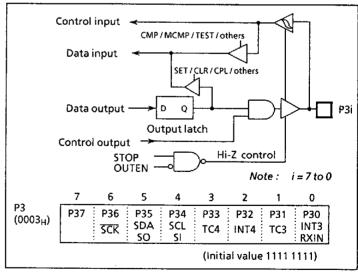

Figure 2-6. Port P3

#### MAINTENANCE

TMP87CH37/K37/M37

## 2.2.5 Port P4 (P47 to P40)

Port P4 is an 8-bit input / output port which can be configured as an input or an output in one-bit unit under software control. Input / output mode is specified by the corresponding bit in the port P4 input/output control register (P4CR). Port P4 is configured as an input if its corresponding P4CR bit is cleared to "0", and as an output if its corresponding P4CR bit is set to "1". During reset, P4CR is initialized to "0", which configures port P4 as an input. The P4 output latches are also initialized to "1".

Data is written into the output latch regardless of the STOP P4CR contents. Therfore initial output data should be OUTEN written into the output latch before setting P4CR. Port P4CRi P4 is also used as a pulse width modulation (PWM) Data input output. When used as a PWM output pin, the output pins should be set to the output mode and beforehand the output latch should be set to "1". Data output Note: Input mode port is read the state of input pin. When input / output mode is used to mixed, the P4i output latch contents of input mode port may be changed by <u>PWMi</u> executing bit manipulation instructions. Note: i = 7 to 0P44 P42 . P41 P40 P46 P45 P43 P47 PWM7 PWM6 PWM5 PWM4 PWM3 PWM2 PWM1 PWM0 (Initial value: 1111 1111)  $(0004_{H})$ P4CR (Initial value: 0000 0000) (000CH) write 0: input mode I/O control for port P4 P4CR only 1 : output mode

Figure 2-7. Port P4 and P4CR

#### 2.2.6 Port P5 (P57 to P50)

Port P5 is an 8-bit input / output port, and is also used as comparator input, a pulse output, and a pulse width modulation (PWM) output. When used as an input port or a secondary function pin, the output latch should be set to "1". The output latches are initialized to "1" during reset.

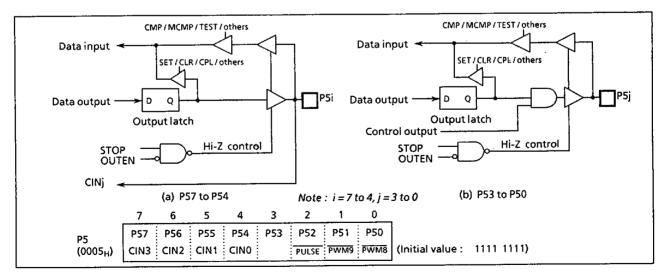

Figure 2-8. Port P5

3-37-50

### 2.2.7 Port P6 (P67 to P60)

Port P6 is an 8-bit input / output port which can be configured as an input or an output in one-bit unit under software control. Input or output mode is selected by the corresponding bit in the input/output control register (P6CR). For example, port P6 is configured as an input if its corresponding P6CR bit is cleared to "0", and as an output if its corresponding bit is set to "1". During reset, P6CR is initialized to "0", which configures port P6 as an input. The P6 output latches are slao initialized to "1".

Data is written into the output latch regardless of the P6CR contents. Therefore initial output data should be written into the output latch before setting P6CR. Pins P63 to P60 are available high current output, so LEDs can be driven directly.

Port P6 is also used as an on screen display (OSD) output (R, G, B, and Y/BL signal). When used as an OSD output pin, the OSD output pins should be set to the output mode and beforehand the port P6 data selection register (P67DS to P64DS) should be set to "1".

Note: Input mode port is read the state of input pin.

When input / output mode is used to mixed, the contents of input mode port may be changed by executing bit manipulation instructions.

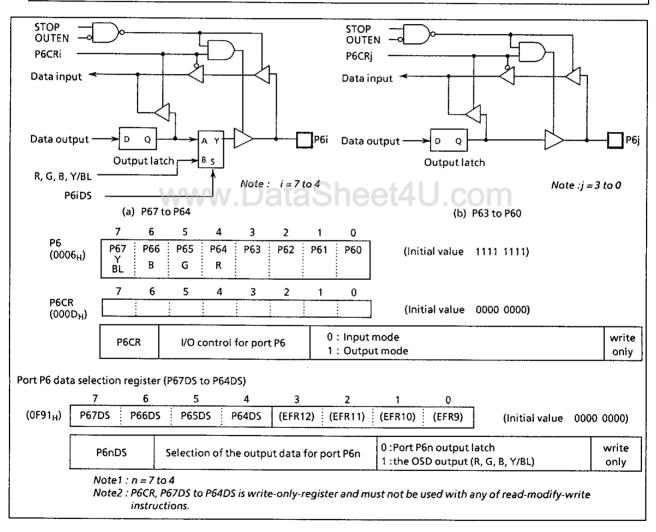

Figure 2-9. Port P6, P6CR, and P67DS to P64DS

Note: Input mode port is read the state of input pin. When input / output mode is used to mixed, the contents of output latch setting input mode may be changed by executing bit manipulation instructions.

Example: Set the lower 4 bit in port P6 (P63 to P60) to the output port and set the other to the input port.

LD

(P6CR), 0FH

; P6CR←0000 1111B

#### 2.2.8 Port P7 (P74 to P70)

**TOSHIBA** 

Port P7 is a 5-bit input / output port, and is also used as a vertical synchronous signal (VD) input and a horizontal synchronous signal (HD) input for the on screen display (OSD) circuitry.

The output latches are initialized to "1" during reset. When used as an input port or a secondary function pin, the output latch should be set to "1".

When a read instruction for port P7 is executed, bits 7 to 5 in P7 are read in as undefined data.

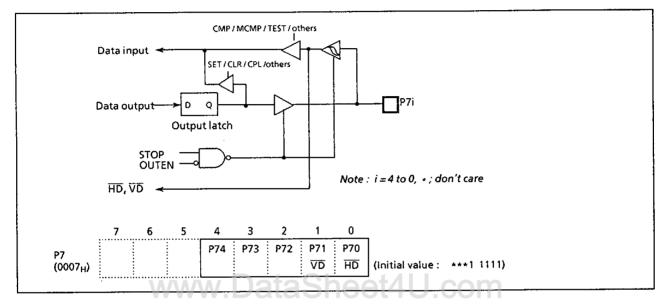

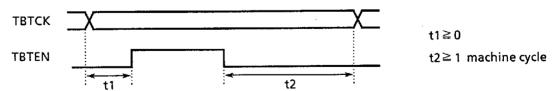

Figure 2-10. Port P7

### 2.3 Time Base Timer (TBT)

The time base timer generates time base for key scanning, dynamic displaying, etc. It also provides a time base timer interrupt (INTTBT). The time base timer is controlled by a control register (TBTCR) shown in Figure 2-12.

An INTTBT is generated on the first rising edge of source clock (the divider output of the timing generator) after the time base timer has been enabled. The divider is not cleared by the program; therefore, only the first interrupt may be generated ahead of the set interrupt period.

The interrupt frequency (TBTCK) must be selected with the time base timer disabled (When the time base timer is changed from enabling to disabling, the interrupt frequency can't be changed.) (both frequency selection and enabling can be performed simultaneously).

Example

Sets the time base timer frequency to fc/216 [Hz] and enables an INTTBT interrupt.

LD (TBTCR), 00001010B

SET (EIRL). 6

### 2.4 Divider Output (DVO)

A 50 % duty pulse can be output using the divider output circuit, which is useful for a piezo-electric buzzer drive. Divider output is from pin P13 (DVO). The P13 output latch should be set to "1" and then the P13 should be configured as an output.

The divider output circuit is controlled by the control register (TBTCR) shown in Figure 2-13.

Note that TBTCR is a write-only register.

DVC	DVOEN Divider output enable/disable		/disable	0 : Disable 1 : Enable

#### 2.5 16-bit Timer / Counter 1 (TC1)

## 2.5.1 Configuration

**TOSHIBA** 

3-37-55

#### 2.5.2 Control

The timer / counter 1 is controlled by a timer / counter 1 control register (TC1CR) and two 16-bit timer registers (TREG1A and TREG1B). Reset does not affect TREG1A and TREG1B.

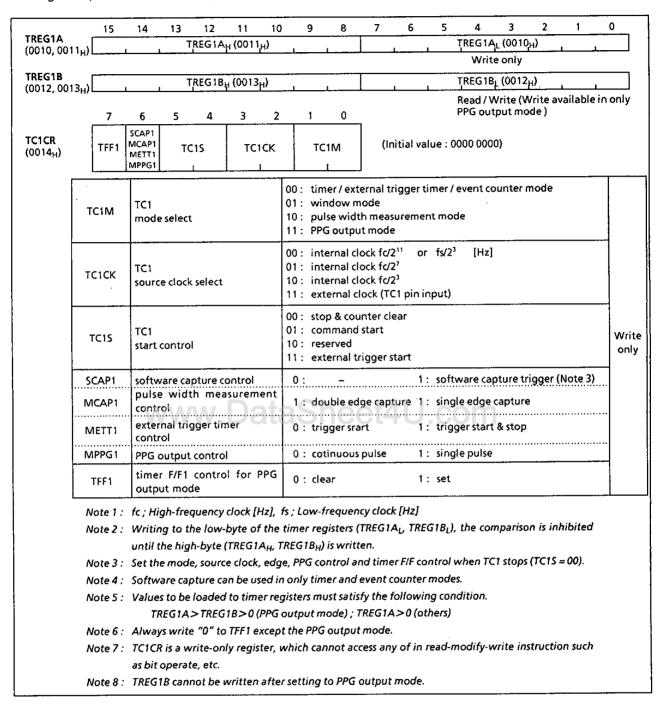

Figure 2-16. Timer Registers and TC1 Control Register

#### 2.5.3 Function

TOSHIBA

Timer/counter 1 has six operating modes: timer, external trigger timer, event counter, window, pulse width measurement, programmable pulse generator output mode.

#### (1) Timer Mode

In this mode, counting up is performed using the internal clock. The contents of TREG1A are compared with the contents of up-counter. If a match is found, an INTTC1 interrupt is generated, and the counter is cleared to "0". Counting up resumes after the counter is cleared. The current contents of up-counter can be transferred to TREG1B by setting SCAP1 (bit 6 in TC1CR) to "1" (software capture function). SCAP1 is automatically cleared after capturing.

Table 2-3. Timer / Counter 1 Source Clock (Internal Clock)

	Source clo	ck	Res	olution	Maximum time setting		
NORMAL1/2,	DLE 1/2 modes			1			
DV7CK = 0	DV7CK = 1	SLOW, SLEEP modes	At fc = 8 MHz	At fs = 32.768 kHz	At fc = 8 MHz	At fs = 32.768 kHz	
fc/2 <sup>3</sup> [Hz]	fc/2³[Hz]	_	1 μs	_	65.5 ms	_	
fc/2 <sup>7</sup>	fc/2 <sup>7</sup>	_	16 µs	-	1.0 s	_	
fc/2 <sup>11</sup>	fs/2³	fs/2³ [Hz]	256 μs	244.14 μs	16.7 s	16.0 s

Example 2: Software capture

LD (TC1CR), 01010000B; SCAP1←1 (Captures) LD WA, (TREG1B); Reads captured value

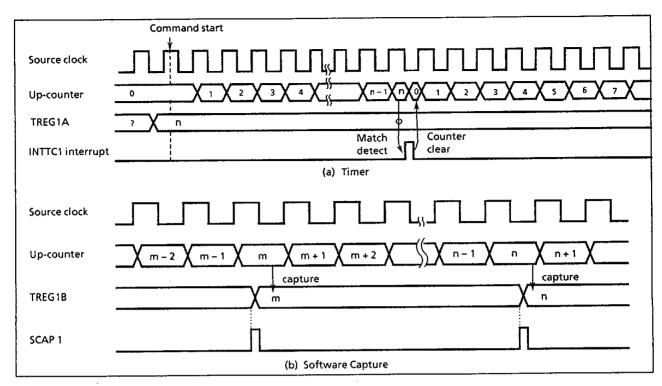

Figure 2-17. Timer Mode Timing Chart

### (2) External Trigger Timer mode

In this mode, counting up is started by an external trigger. This trigger is the edge of the TC1 pin input. Either the rising or falling edge can be selected with INT2ES. Edge selection is the same as for the external interrupt input INT2 pin. Source clock is used an internal clock selected with TC1CK. The contents of TREG1A is compared with the contents of up-counter. If a match is found, an INTTC1 interrupt is generated, and the counter is cleared to "0" and halted. The counter is restarted by the selected edge of the TC1 pin input.

The TC1 pin input has the same noise rejection as the INT2 pin; therefore, pulses of 7/fc [s] or less are rejected as noise. A pulse width of 24/fc [s] or more is required for edge detection in NORMAL1/2 or IDLE 1/2 mode. The noise rejection circuit is turned off in SLOW and SLEEP modes. But, a pulse width of 4/fs [s] or more is required.

```
Detects rising edge (in TC1 pin input) and generates an interrupt 100 \mus later.
Example 1:
               (at fc = 8 MHz)

ΕI (TC1CR), 01110100B; Starts TC1 with an external trigger, METT = 1 LD

3-37-58

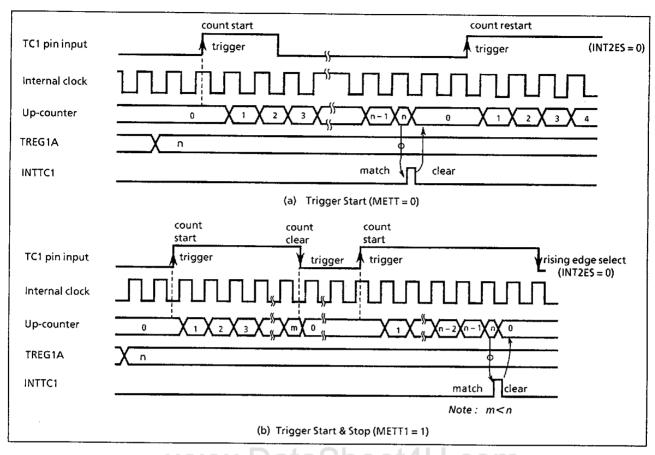

Figure 2-18. External Trigger Timer Mode Timing Chart

#### (3) Event Counter Mode

In this mode, events are counted at the edge of the TC1 pin input. Either the rising or falling edge can be selected with INT2ES in EINTCR. The contents of TREG1A are compared with the contents of up-counter. If a match is found, an INTTC1 interrupt is generated, and the counter is cleared. The maximum applied frequency is fc/24 [Hz] in NORMAL1/2 or IDLE1/2 mode and fs/24 [Hz] in SLOW or SLEEP mode.

Setting SCAP1 to "1" transferes the current contents of up-counter to TREG1B (software capture function). SCAP1 is automatically cleared after capturing.

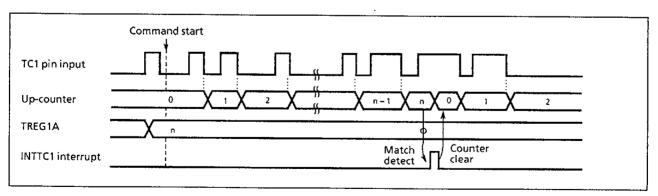

Figure 2-19. Event Counter Mode Timing Chart (INT2ES = 1)

3-37-59

## MAINTENANCE

### (4) Window mode

Counting up is performed on the rising edge of the pulse that is the logical AND-ed product of the TC1 pin input (window pulse) and an internal clock. The contents of TREG1A are compared with the contents of up-counter. If a match is found, an INTTC1 interrupt is generated, and the counter is cleared. Positive or negative logic for the TC1 pin input can be selected with INT2ES. Setting SCAP1 to "1" transferres the current contents of up-counter to TREG1B. It is necessary that the maximum applied frequency (TC1 input) be such that the counter value can be analyzed by the program. That is, the frequency must be considerably slower than the selected internal clock.

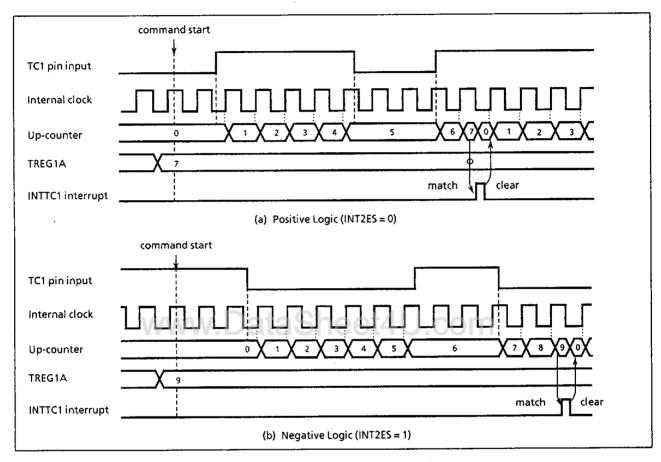

Figure 2-20. Window Mode Timing Chart

#### (5) Pulse width measurement mode

Counting is started by the external trigger (set to external trigger start by TC1S). The trigger can be selected either the rising or falling edge of the TC1 pin input. The source clock is used an internal clock. On the next falling (rising) edge, the counter contents are transferred to TREG1B and an INTTC1 interrupt is generated. The counter is cleared when the single edge capture mode is set. When double edge capture is set, the counter continues and, at the next rising (falling) edge, the counter contents are again transferred to TREG1B. If a falling (rising) edge capture value is required, it is necessary to read out TREG1B contents until a rising (falling) edge is detected. Falling or rising edge is selected with INT2ES, and single edge or double edge is selected with MCAP1 ( bit 6 in TC1CR).

	LD	(HPULSE + 1), (TREG1BH)		
	RETI			

3-37-61

(6) Programmable Pulse Generate (PPG) output mode

Counting is started by an edge of the TC1 pin input (either the rising or falling edge can be selected) or by a command. The source clock is used an internal clock. First, the contents of TREG1B are compared with the contents of the up-counter. If a match is found, timer F/F1 output is toggled. Next, timer F/F1 is again toggled and the counter is cleared by matching with TREG1A. An INTTC1 interrupt is generated at this time. Timer F/F output is connected to the P14 (PPG) pin. In the case of PPG output, set the P14 output latch to "1" and configure as an output with P1CR4. Timer F/F1 is cleared to "0" during reset. The timer F/F1 value can also be set by program and either a positive or negative logic pulse output is available. Also, writing to the TREG1B is not possible unless the timer / counter 1 is set to the PPG output mode with TC1M.

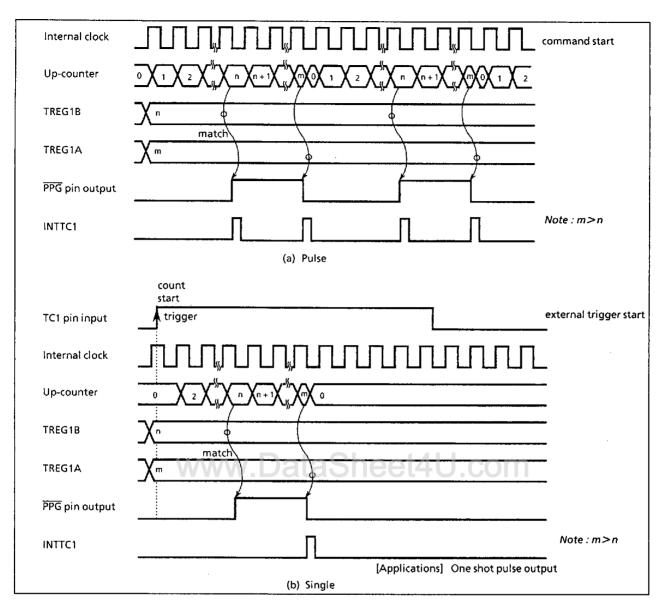

Figure 2-22. PPG Output Mode Timing Chart

## 2.6 16-bit Timer / Counter 2 (TC2)

## 2.6.1 Configuration

www.DataSheet4U.com

**TOSHIBA** 

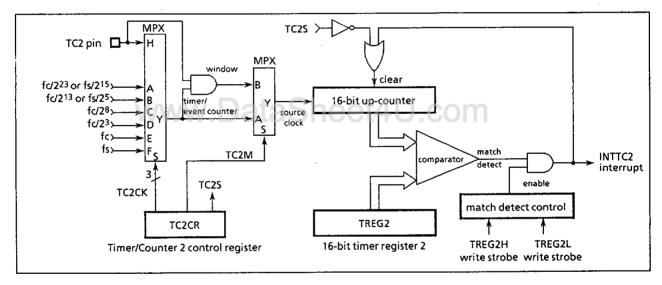

Figure 2-24. Timer / Counter 2 (TC2)

3-37-64

#### 2.6.2 Control

The timer / counter 2 is controlled by a timer / counter 2 control register (TC2CR) and a 16-bit timer register 2 (TREG2). Reset does not affect the TREG2.

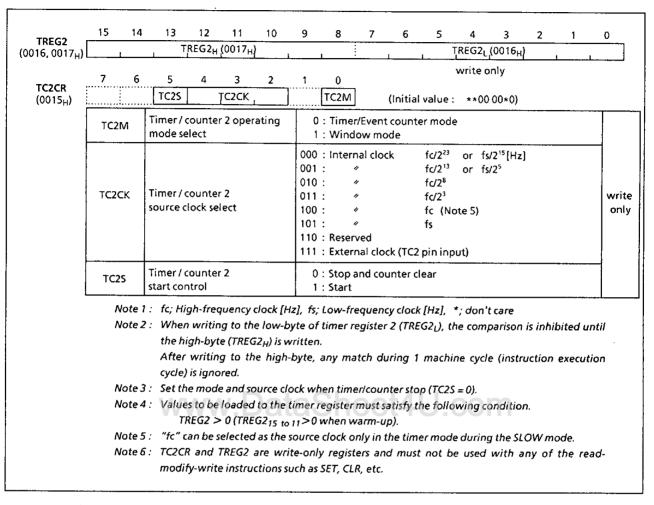

Figure 2-25. Timer Register 2 and TC2 Control Register

#### 2.6.3 Function

The timer / counter 2 has three operating modes: timer, event counter and window modes. Also timer / counter 2 is used for warm-up when switching from SLOW mode to NORMAL2 mode.

### (1) Timer Mode

In this mode, the internal clock is used for counting up. The contents of TREG2 are compared with the contents of up-counter. If a match is found, a timer/counter 2 interrupt (INTTC2) is generated, and the counter is cleared. Counting up is resumed after the counter is cleared.

Also, when "fc" is selected as the source clock during SLOW mode, the lower 11 bits of TREG2 are ignored and an INTTC2 interrupt is generated by matching the upper 5 bits. Thus, in this case, only the TREG2<sub>H</sub> setting is necessary.

Table 2-4. Source Clock (Internal Clock) for Timer / Counter 2

	Source	clock		Re	solution	Maximum time setting		
NORMAL1/2, DV7CK = 0	DV7CK = 1	SLOW mode	SLEEP mode	At fc = 8 MHz	At fs = 32.768 kHz	At fc = 8 MHz	At fs = 32.768 kHz	
fc/2 <sup>23</sup> [Hz] fc/2 <sup>13</sup> fc/2 <sup>8</sup> fc/2 <sup>3</sup>	fs/2 <sup>15</sup> [Hz] fs/2 <sup>5</sup> fc/2 <sup>8</sup> fc/2 <sup>3</sup>	fs/2 <sup>15</sup> [Hz] fs/2 <sup>5</sup> - - fc (Note)	fs/2 <sup>15</sup> [Hz] fs/2 <sup>5</sup> - - -	1.05 s 1.02 ms 32 \mu s 1 \mu s 125 ns	1 s 1 ms	19.1 hour 1.1 min 2.1 s 65.5 ms 7.9 ms	18.2 hour 1 min	
fs	fs	_	-	_	30.5 μs	-	2 s	

Note: "fc" can be used only in the timer mode.

Example : Sets the timer mode with source clock fc/23 [Hz] and generates an interrupt every

25 ms (at fc = 8 MHz).

LD (TC2CR), 00001100B; Sets the TC2 mode and source clock LDW (TREG2), 61A8H; Sets TREG2 (25 ms  $\div$  23/fc = 61A8H)

SET (EIRH), EF14 ; Enables INTTC2 interrupt

ΕI

LD (TC2CR), 00101100B; Starts TC2

#### (2) Event Counter Mode

In this mode, events are counted on the rising edge of the TC2 pin input. The contents of TREG2 are compared with the contents of the up-counter. If a match is found, an INTTC2 interrupt is generated, and the counter is cleared. The maximum frequency applied to the TC2 pin is fc/24 [Hz] in NORMAL1/2 or IDLE1/2 mode, and fs/24 [Hz] in SLOW or SLEEP mode. Two or more machine cycles are required for both the "H" and "L" levels of the pulse width.

Example : Sets the event counter mode and generates an INTTC2 interrupt 640 counts later.

LD (TC2CR), 00011100B; Sets the TC2 mode

LDW (TREG2), 640 ; Sets TREG2 SET (EIRH). EF14 ; Enables INTTC2

ΕI

LD (TC2CR), 00111100B; Starts TC2

#### (3) Window Mode

In this mode, counting up is performed on the rising edge of the pulse that is the logical AND-ed product of the TC2 pin input (window pulse) and an internal clock. The internal clock is selected with TC2CK. The contents of TREG2 are compared with the contents of up-counter. If a match is found, an INTTC2 interrupt is generated, and the up-counter is cleared to "0". It is necessary that the maximum applied frequency (TC2 input) be such that the counter value can be analyzed by the program. That is, the frequency must be considerably slower than the selected internal clock.

Example : Generates an interrupt, inputting "H" level pulse width of 120 [ms] or more.

## 2.7 8-Bit Timer / Counter 3 (TC3)

## 2.7.1 Configuration

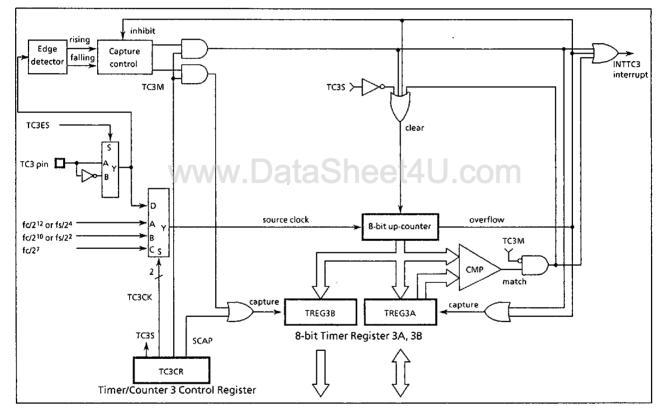

Figure 2-27. Timer/Counter 3

www.DataSheet4U.com

#### MAINTENANCE

TMP87CH37/K37/M37

#### 2.7.2 Control

The timer / counter 3 is controlled by a timer / counter 3 control register (TC3CR) and two 8-bit timer registers (TREG3A and TREG3B). Reset does not affect these timer registers.

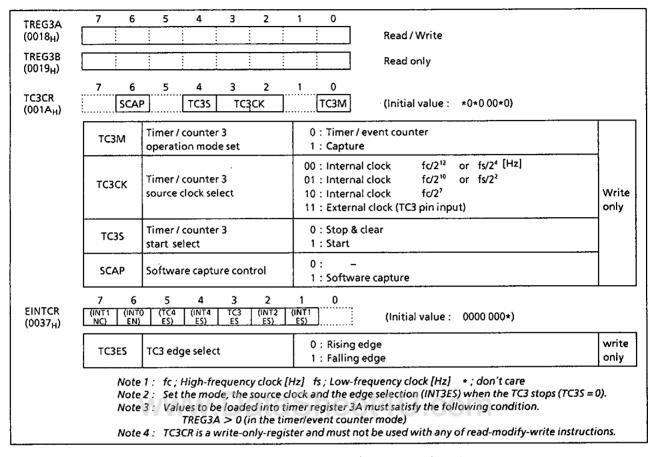

Figure 2-28. Timer Register 3 and TC3 Control Registers

#### 2.7.3 Function

The timer / counter 3 has three operating modes: timer, event counter, and capture mode.

#### (1) Timer Mode

In this mode, the internal clock shown in Table 2-5 is used for counting up. The contents of TREG3A are compared with the contents of up-counter. If a match is found, a timer / counter 3 interrupt (INTTC3) is generated, and the up-counter is cleared. Counting up resumes after the up-counter is cleared. The current contents of up-counter are loaded into TREG3B by setting SCAP (bit 6 in TC3CR) to "1". SCAP is automatically cleared after capturing.

Table 2-5. Source Clock (Internal Clock) for Timer Counter 3

Source clock		Resolution		Maximum setting time	
NORMAL1/2, IDLE1/2 mode	SLOW, SLEEP mode	fc = 8 MHz	fs = 32.768 kHz	fc = 8 MHz	fs = 32.768 kHz
fc/2 <sup>12</sup> or fs/2 <sup>4</sup> [Hz] fc/2 <sup>10</sup> or fs/2 <sup>2</sup>	fs/2 <sup>4</sup> [Hz]	512 μs 128 μs	488.28 μs 122.07 μs	131.1 ms 32.6 ms	124.5 ms 31,12 ms
fc/2 <sup>7</sup>	_	16 μs	-	4.1 ms	-

3-37-68

#### (2) Event Counter Mode

In this mode, the TC3 pin input pulses are used for counting up. Either the rising or falling edge can be selected with TC3ES (bit 3 in EINTCR). The contents of TREG3A are compared with the contents of the up-counter. If a match is found, an INTTC3 interrupt is generated and the counter is cleared. The maximum applied frequency is fc/2<sup>4</sup> [Hz] in NORMAL1/2 or IDLE1/2 mode, and fs/2<sup>4</sup> [Hz] in SLOW or SLEEP mode. Two or more machine cycles are required for both the high and low levels of the pulse width.

The current contents of up-counter are loaded into TREG3B by setting SCAP (bit 6 in TC3CR) to "1". SCAP is automatically cleared after capturing.

Example : Genérates an interrupt every 0.5 [s], inputting 50Hz pulses to the TC3 pin.

LD (TC3CR), 00001100B; Sets TC3 mode and source clock

LD (TREG3A), 19H ;  $0.5 [s] \div 1/50 = 25 = 19_H$ SET (EIRH) .EF8 ; Enables INTTC3 interrupt

ΕI

LD (TC3CR), 00011100B ; Start TC3

#### (3) Capture Mode

The pulse width, period and duty of the TC3 pin input are measured in this mode, which can be used in decoding the remote control signals, etc. The counter is free running by the internal clock. On the rising (falling) edge of the TC3 pin input, the current contents of counter is loaded into TREG3A, then the up-counter is cleared to "0" and an INTTC3 interrupt is generated. On the falling (rising) edge of the TC3 pin input, the current contents of the counter is loaded into TREG3B. In this case, counting continues. On the next rising (falling) edge of the TC3 pin input, the current contents of counter are loaded into TREG3A, then the counter is cleared again and an interrupt is generated. If the counter overflows before the edge is detected, FF<sub>H</sub> is set into TREG3A, and the counter is cleared and an overflow interrupt (INTTC3) is generated. During interrupt processing, it can be determined whether or not there is an overflow by checking whether or not the TREG3A value is FF<sub>H</sub>. Also, after an interrupt (capture to TREG3A, or overflow detection) is generated, capture and overflow detection are halted until TREG3A has been read out; however, the counter continues.

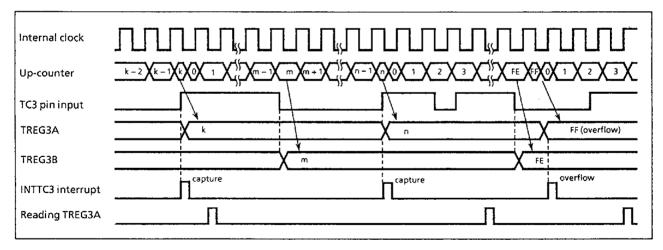

Figure 2-29. Timing Chart for Capture Mode (TC3ES = 0)

## 2.8 8-bit Timer / Counter (TC4)

## 2.8.1 Configuration

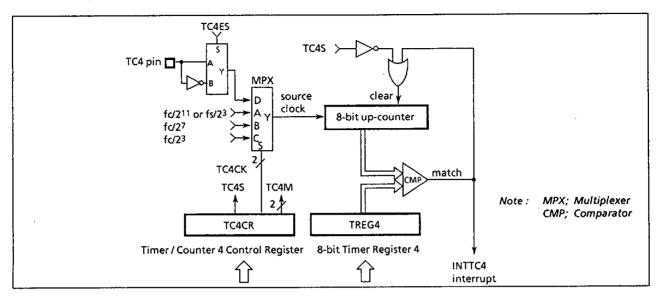

Figure 2-30. Timer/Counter 4

#### 2.8.2 Control

The timer / counter 4 is controlled by a timer / counter 4 control register (TC4CR) and an 8-bit timer register 4 (TREG4). Reset does not affect TREG4.

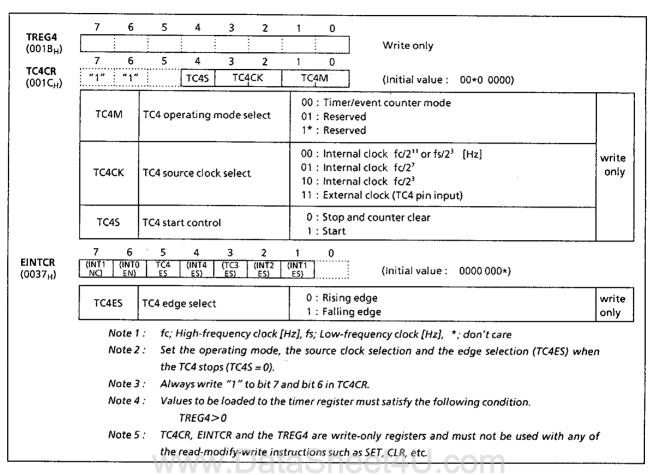

Figure 2-31. Timer Register 4 and TC4 Control Registers

#### 2.8.3 Function

The timer / counter 4 has two operating modes: timer and event counter mode.

#### (1) Timer Mode

In this mode, the internal clock is used for counting up. The contents of TREG4 are compared with the contents of up-counter. If a match is found, a timer/counter 4 interrupt (INTTC4) is generated and the counter is cleared. Counting up resumes after the counter is cleared.

Table 2-6. Source Clock (Internal Clock) for Timer/Counter 4

Source clock		Res	olution	Maximum setting time	
NORMAL1/2, IDLE1/2 mode	SLOW, SLEEP mode	At fc = 8 MHz	At fs = 32.768 kHz	At fc = 8 MHz	At fs = 32.768 kHz
fc/2 <sup>11</sup> or fs/2 <sup>3</sup> [Hz]	fs/2³ [Hz]	256 μs	244.14 µs	65.28 ms	62.25 ms
fc/2 <sup>7</sup>	_	16 μs	_	4.08 ms	p
fc/2 <sup>3</sup>	_	1 <i>μ</i> s	-	255 μs	_

#### (2) Event Counter Mode

In this mode, the TC4 pin input (external clock) pulse is used for counting up. Either the rising or falling edge can be selected with TC4ES (bit 5 in EINTCR). The contents of TREG4 are compared with the contents of the up-counter. If a match is found, an INTTC4 interrupt is generated and the counter is cleared. The maximum applied frequency is fc/2<sup>4</sup> [Hz] in NORMAL1/2 or IDLE1/2 mode, and fs/2<sup>4</sup> [Hz] in SLOW or SLEEP mode. Two or more machine cycles are required for both the high and low levels of the pulse width.

#### 2.9 Serial Bus Interface (SBI)

The 87CH37/K37/M37 has a 1-channel serial bus interface which employs a clocked-synchronous 8-bit serial bus interface and an I<sup>2</sup>C bus (a bus system by Philips).

The serial bus interface is connected to an external device through P35 (SDA) and P34 (SCL) in the  $I^2C$  bus mode; and through P36 (SCK), P35 (SO), and P34 (SI) in the clocked-synchronous 8-bit SIO mode.

The serial bus interface pins are also used for the P3 port. When used for serial bus interface pins, set the P3 output latches of these pins to "1". When not used for serial bus interface pins, the P3 port is used as a normal I/O port.

#### 2.9.1 Configuration

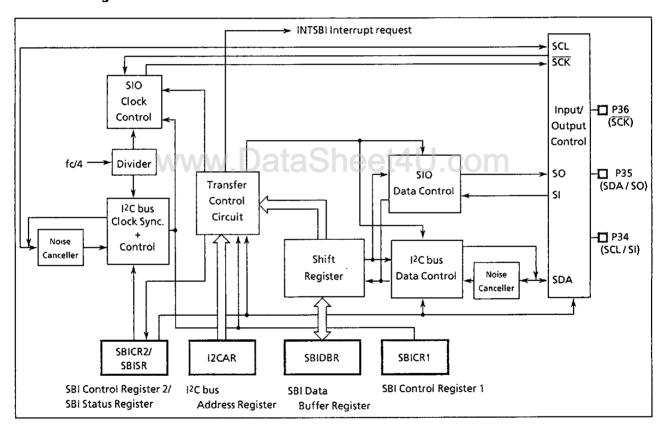

Figure 2-32. Serial Bus Interface (SBI)

# 2.9.2 Serial Bus Interface (SBI) Control

The following reginsters are used for control and operation status monitoring when using the serial bus interface (SBI).

- Serial bus interface control register 1 (SBICR1)
- Serial bus interface control register 2 (SBICR2)
- Serial bus interface data buffer register (SBIDBR)
- I<sup>2</sup>C bus address register (I2CAR)
- Serial bus interface status register (SBISR)

The above registers differ depending on a mode to be used.

Refer to Section "2.9.4 I<sup>2</sup>C bus Mode Control" and "2.9.6 Clocked-synchronous 8-bit SIO Mode Control".

# 2.9.3 The Data Formats in the I<sup>2</sup>C bus Mode

The data formats when using the 87CH37/K37/M37 in the I<sup>2</sup>C bus mode are shown below.

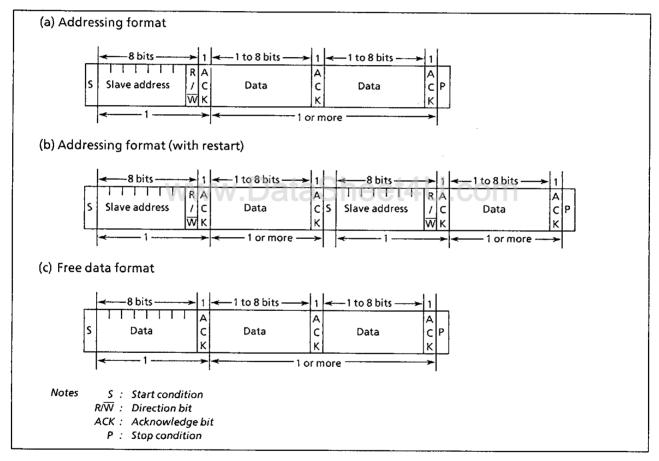

Figure 2-33. Data Format

## 2.9.4 I<sup>2</sup>C Bus Mode Control

The following registers are used for control and operation status monitoring when using the serial bus interface (SBI) in the I<sup>2</sup>C bus mode.

Figure 2-35. Serial Bus Interface Control Register 2 / Serial Bus Interface Status Register in the I<sup>2</sup>Cbus Mode

1: Last received bit "1"

#### (1) Acknowledge mode specification

Set the ACK (bit 4 in the SBICR1) to "1" for operation in the acknowledge mode. The 87CH37/K37/M37 generates an additional clock pulse for an acknowledge signal when operating in the master mode, and it counts a clock pulse for an acknowledge signal when operating in the slave mode. In the transmitter mode during this clock pulse cycle, the SDA pin is released in order to receive the acknowledge signal from the receiver. In the receiver mode during this clock pulse cycle, the SDA pin is set to the low level in order to generate the acknowledge signal.

Clear the ACK to "0" for operation in the non-acknowledge mode. The 87CH37/K37/M37 does not generate a clock pulse for the acknowledge signal when operating in the master mode, and it does not count a clock pulse for the acknowledge signal when operating in the slave mode.

#### (2) Number of transfer bits

The BC (bits 7 to 5 in the SBICR1) is used to select a number of bits for next transmitting and receiving data

Since the BC is cleared to "000" by a start condition, a slave address and direction bit transmissions are executed in 8 bits. Other than these, the BC retains a specified value.

#### (3) Serial clock

#### a. Clock source

The SCK (bits 2 to 0 in the SBICR1) is used to select a maximum transfer frequency outputed on the SCL pin in the master mode.

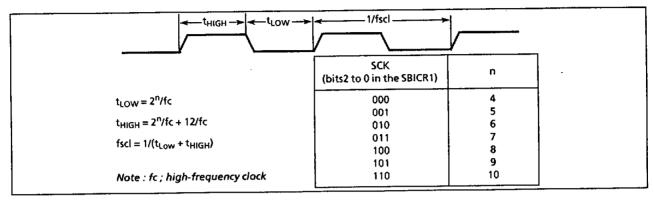

Figure 2-36. Clock Source

#### b. Clock synchronization

In the I<sup>2</sup>C bus mode, in order to wired-AND a bus, a master device which pulls down a clock line to low-level, in the first place, invalidate a clock pulse of another master device which generates a high-level clock pulse. The master device with a high-level clock pulse needs to detect the situation and implement the following procedure.

The 87CH37/K37/M37 have a clock synchronization function for normal data transfer even when more than one master exists on a bus.

The example explains clock synchronization procedures when two masters simultaneously exist on a bus.

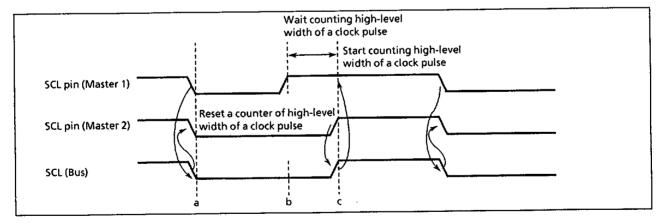

Figure 2-37. Clock Synchronization

As Master 1 pulls down the SCL pin to the low-level at point "a", the SCL line of the bus becomes the low-level. After detecting this situation, Master 2 resets a counter of high-level width of an own clock pulse and sets the SCL pin to the low-level.

Master 1 finishes counting low-level width of an own clock pulse at point "b" and sets the SCL pin to the high-level. Since Master 2 holds the SCL line of the bus at the low-level, Master 1 waits for counting high-level width of an own clock pulse. After Master 2 finishes counting low-level width of an own clock pulse at point "c" and Master 1 detects the SCL line of the bus at the high-level and starts counting high-level of an own clock pulse.

The clock pulse on the bus is determinded by the master device with the shortest high-level width and the master device with the longest low-level width from among those master devices connected to the bus.

# (4) Slave address and address recognition mode specification

When the 87CH37/K37/M37 is used as a slave device, set the slave address and ALS to the I2CAR. Clear the ALS to "0" for the address recognition mode.

## (5) Master/slave selection

Set the MST (bit 7 in the SBICR2) to "1" for operating the 87CH37/K37/M37 as a master device. Clear the MST to "0" for operation as a slave device. The MST is cleared to "0" by the hardware after a stop condition on a bus is detected or arbitration is lost.

#### (6) Transmitter/receiver selection

Set the TRX (bit 6 in the SBICR2) to "1" for operating the 87CH37/K37/M37 as a transmitter. Clear the TRX to "0" for operation as a receiver. When data with an addressing format is transferred in the slave mode, when a slave address with the same value that an I2CAR or a GENERAL CALL is received (all 8-bit data are "0" after a start condition), the TRX is set to "1" by the hardware if the direction bit  $(R/\overline{W})$  sent from the master device is "1", and is cleared to "0" by the hardware if the bit is "0". In the master mode, after an acknowledge signal is returned from the slave device, the TRX is cleared to "0" by the hardware if a transmitted direction bit is "1", and is set to "1" by the hardware if it is "0". When an acknowledge signal is not returned, the current condition is maintained.

The TRX is cleared to "0" by the hardware after a stop condition on the I<sup>2</sup>C bus is detected or arbitration is lost.

# (7) Start/stop condition generation

When the BB (bit 5 in the SBICR2) is "0", the slave address and the direction bit which are set to the SBIDBR are output on a bus after generating a start condition by writing "1" to the MST, TRX, BB, and PIN. It is necessary to set transmitted data to the data buffer register (SBIDBR) and set "1" to ACK beforehand.

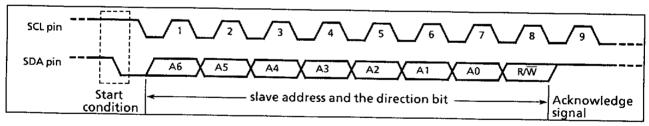

Figure 2-38. Start Condition Generation and Slave Address Generation

When the BB is "1", a sequence of generating a stop condition is started by writing "1" to the MST, TRX, and PIN, and "0" to the BB. Do not modify the contents of MST, TRX, BB and PIN until a stop condition is generated on a bus.

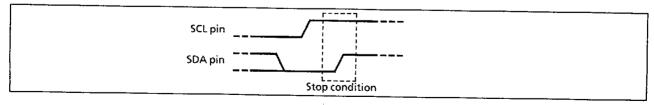

Figure 2-39. Stop Condition Generation

3-37-77

The bus condition can be indicated by reading the contents of the BB (bit 5 in the SBISR). The BB is set to "1" when a start condition on a bus is detected, and is cleared to "0" when a stop condition is detected on a bus.

# (8) Interrupt service request and cancel

When a serial bus interface interrupt request (INTSBI) occurs, the PIN (bit 4 in the SBISR) is cleared to "0". During the time that the PIN is "0", the SCL pin is pulled down to the low level.

The PIN is cleared to "0" when 1-word of data is transmitted or received. Either writing/reading data to/from the SBIDBR sets the PIN to "1".

The time from the PIN being set to "1" until the SCL pin is released takes t<sub>LOW</sub>.

In the address recognition mode (ALS = 0), the PIN is cleared to "0" when the received slave address is the same as the value set to the I2CAR or when a GENERAL CALL is received (all 8-bit data are "0" after a start condition). Although the PIN (bit 4 in the SBICR2) can be set to "1" by the program, the PIN is not cleared to "0" when it is written "0".

# (9) Serial bus interface operation mode selection

The SBIM (bit 3, 2 in the SBICR2) is used to specify the serial bus interface operation mode. Set the SBIM to "10" when used in the I<sup>2</sup>C bus mode after confirming that input signal via port is high-level. Switch a mode to port after confirming that the bus is free.

## (10) Arbitration lost detection monitor

Since more than one master device can exist simultaneously on a bus in the I<sup>2</sup>C bus mode, a bus arbitration procedure is implemented in order to guarantee the contents of transferred data.

Adata on the SDA line is used for bus arbitration of the I<sup>2</sup>C bus.

The following shows an example of a bus arbitration procedure when two master devices exist simultaneously on a bus. Master 1 and Master 2 output the same data until point "a". After Master 1 outputs "1" and Master 2, "0", the SDA line of the bus is wire-AND and the SDA line is pulled down to the low level by Master 2. When the SCL line of the bus is pulled up at point "b", the slave device reads a data on the SDA line, that is, data in Master 2. A data transmitted from Master 1 becomes invalid. The state in Master 1 is called ARBITRATION LOST. A master device which loses arbitration releases the SDA pin in order not to effect data transmitted from other masters with arbitration. When more than one master sends the same data at the first word, arbitration occurs continuously after the second word.

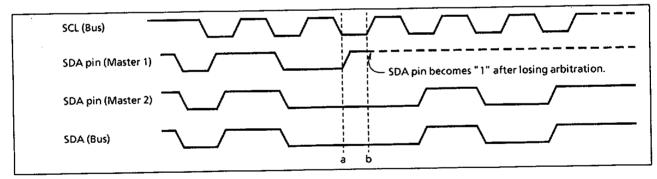

Figure 2-40. Arbitration Lost

The 87CH37/K37/M37 compares levels of the SDA line on a bus with those of the 87CH37/K37/M37 SDA pin at the rising edge of the SCL line. If the levels are unmatched, arbitration is lost and the AL (bit 3 in the SBISR) is set to "1".

When the AL is set to "1", the MST and TRX are cleared to "0" and the mode is switched to a slave receiver mode. The 87CH37/K37/M37 generates the clock pulse until data is transmitted when the AL is "1".

The AL is cleared to "0" by writing/reading data to/from the SBIDBR or writing data to the SBICR2.

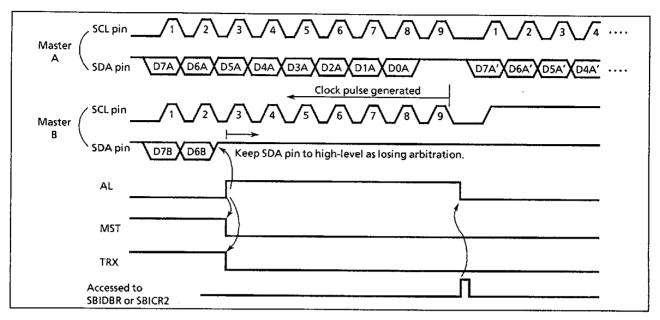

Figure 2-41. Example when 87CH37/K37/M37 is a Master Device B

## (11) Slave address match detection monitor

The AAS (bit 2 in the SBISR) is set to "1" in the slave mode, in the address recognition mode (ALS = 0), when receiving GENERAL CALL or a slave address with the same value that is set to the I2CAR. When the ALS is "1", the AAS is set to "1" after receiving the first 1-word of data. The AAS is cleared to "0" by writing / reading data to / from a data buffer register.

#### (12) GENERAL CALL detection monitor

The AD0 (bit 1 in the SBISR) is set to "1" in the slave mode, when all 8-bit received data is "0", after a start condition (GENERAL CALL). The AD0 is cleared to "0" when a start or stop condition is detected on a bus.

#### (13) Last received bit monitor

The SDA value stored at the rising edge of the SCL is set to the LRB (bit 0 in the SBISR). In the acknowledge mode, immediately after an INTSBI interrupt request is generated, an acknowledge signal is read by reading the contents of the LSB.

## 2.9.5 Data Transfer in I<sup>2</sup>C bus Mode

#### (1) Device Initialization

Set the ACK, and SCK in the SBICR1. Clear "0" to bit 7 to 5 and 3.

Set a slave address and the ALS (ALS = 0 when an addressing format) to the I2CAR.

After confirming that input signals via port are high-level, for specifying the default setting to a slave receiver mode, clear "0" to the MST, TRX, BB and set "1" to the PIN, "10" to the SBIM, and "0" to bit 0 and 1 in the SBICR2.

### TMP87CH37/K37/M37

## (2) Start Condition and Slave Address Generation

Confirm a bus free status (when BB = 0).

Set the ACK to "1" and specify a slave address and a direction bit to be transmitted to the SBIDBR. When the BB is "0", the start condition are generated and the slave address and the direction bit which are set to the SBIDBR are output on a bus by writing "1" to the MST, TRX, BB and PIN. A slave device receives these data and pulls down the SDA line on a bus to the low-level at the acknowledge signal timing. An INTSBI interrupt request occurs at the 9th falling edge of the SCL clock cycle, and the PIN is cleared to "0". The SCL pin is pulled down to the low-level while the PIN is "0". When an interrupt request occurs, the TRX changes by the hardware according to the direction bit only when an acknowledge signal is returned from the slave device.

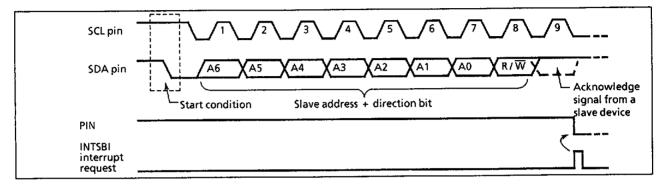

Figure 2-42. Start Condition Generation and Slave Address Transfer

#### (3) 1-word Data Transfer

Check the MST by the INTSBI interrupt process after a 1-word data transfer is completed, and determine whether the mode is a master or slave.

## a. When the MST is "1" (Master mode)

Check the TRX and determine whether the mode is a transmitter or receiver.

#### ① When the TRX is "1" (Transmitter mode)

Check the LRB. When the LRB is "1", a receiver does not request data. Implement the process to generate a stop condition (Refer to 2.9.5. (4)) and terminate data transfer.

When the LRB is "0", the receiver requests new data. When the next transmitted data is other than 8 bits, set the BC and write the transmitted data to the SBIDBR. After writing the data, the PIN becomes "1", a serial clock pulse is generated for transferring a new 1-word of data from the SCL pin, and then the 1-word data is transmitted. After the data is transmitted, an INTSBI interrupt request occurs. The PIN becomes "0" and the SCL pin is pulled down to the low-level. If the data to be transferred is more than one word in length, repeat the procedure from the LRB checking above.

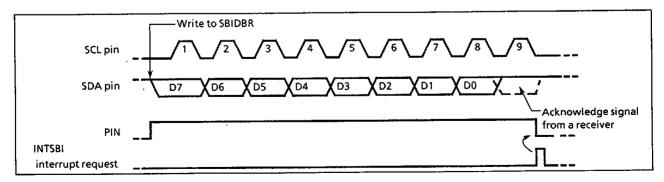

Figure 2-43. Example when BC = "000", ACK = "1" in Transmitter Mode

3-37-80

### ② When the TRX is "0" (Receiver mode)

When the next transmitted data is other than 8 bits, set the BC again. Set the ACK to "1" and read the received data from the SBIDBR (data which is read immediately after a slave address is sent is undefined). After the data is read, the PIN becomes "1". The 87CH37/K37/M37 outputs a serial clock pulse to the SCL to transfer new 1-word of data and sets the SDA pin to "0" at the acknowledge signal timing.

An INTSBI interrupt request occurs and the PIN becomes "0". Then the 87CH37/K37/M37 pulls down the SCL pin to the low-level. The 87CH37/K37/M37 outputs a clock pulse for 1-word of data transfer and the acknowledge signal each time that received data is read from the SBIDBR.

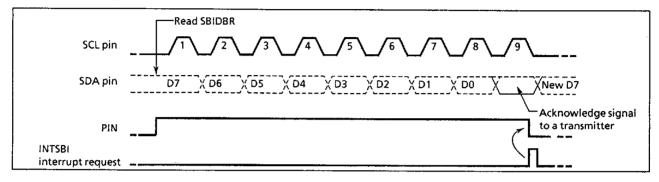

Figure 2-44. Example when BC = "000", ACK = "1" in Receiver Mode

In order to terminate transmitting data to a transmitter, clear the ACK to "0" before reading data which is 1-word before the last data to be received. The last data does not generate a clock pulse for the acknowledge signal. After the data is transmitted and an interrupt request has occurred, set the BC to "001" and read the data. The 87CH37/K37/M37 generates a clock pulse for a 1-bit data transfer. Since the master device is a receiver, the SDA line on a bus keeps the high-level. The transmitter receives the high-level signal as an ACK signal. The receiver indicates to the transmitter that data transfer is complete.

After 1-bit data is received and an interrupt request has occurred, the 87CH37/K37/M37 generates a stop condition (Refer to 2.9.5. (4)) and terminates data transfer.

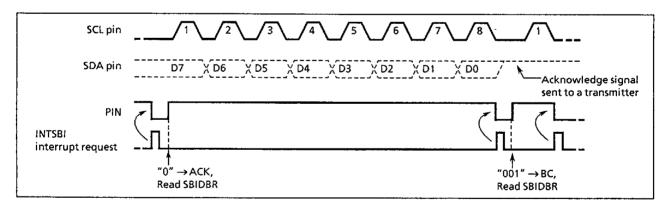

Figure 2-45. Termination of Data Transfer in Master Receiver Mode

#### b. When the MST is "0" (Slave mode)

In the slave mode, an INTSBI interrupt request occurs when the 87CH37/K37/M37 receives a slave address or a GENERAL CALL from the master device, or when a GENERAL CALL is received and data transfer is complete after matching a received slave address. In the master mode, the 87CH37/K37/M37 operates in a slave mode if it is losing arbitration. An INTSBI interrupt request occurs when word data transfer terminates after losing arbitration. When an INTSBI interrupt request occurs, the PIN (bit 4 in the SBICR2) is cleared, and the SCL pin is pulled down to the low-level. Either reading/writing from/to the SBIDBR or setting the PIN to "1" releases the SCL pin after taking t<sub>LOW</sub> time.

In the slave mode, the 87CH37/K37/M37 operates either in normal slave mode or in slave mode after losing arbitration.

Check the AL (bit 3 in the SBISR), the TRX (bit 6 in the SBISR), the AAS (bit 2 in the SBISR), and the ADO (bit 1 in the SBISR) and implements processes according to conditions listed in the next table.

Table 2-7. Operation in the Slave Mode

TRX	AL	AAS	AD0	Conditions	Process
1	1	1	0	The 87CH37/K37/M37 loses arbitration when transmitting a slave address and receives a slave address of which the value of the direction bit sent from another master is "1".	Set the number of bits in 1-word to the BC and write transmitted data to the SBIDBR.
	0	1	0	In the slave receiver mode, the 87CH37/K37/M37 receives a slave address of which the value of the direction bit sent from the master is "1".	
		0	0	In the slave transmitter mode, 1-word data is transmitted.	Check the LRB. If the LRB is set to "1", set the PIN to "1" since the receiver does not request next data. Then, clear the TRX to "0" release the bus. If the LRB is cleared to "0", set the number of bits in a word to the BC and write transmitted data to the SBIDBR
		<u> </u>			since the receiver requests next data.
0	1	1	1/0	The 87CH37/K37/M37 loses arbitration when transmitting a slave address and receives a slave address or GENERAL CALL of which the value of the direction bit sent from another master is "0".	Read the SBIDBR for setting the PIN to "1" (reading dummy data) or set the PIN to "1".
ļ	 	0	0	The 87CH37/K37/M37 loses arbitration when transmitting a slave address or data and terminates transferring word data.	
	0	1	1/0	In the slave receiver mode, the 87CH37/K37/M37 receives a slave address or GENERAL CALL of which the value of the direction bit sent from the master is "0".	
		0	1/0	In the slave receiver mode, the 87CH37/K37/M37 terminates receiving of 1-word data.	Set the number of bits in a word to the BC and read received data from the SBIDBR.

#### (4) Stop Condition Generation

When the BB is "1", a sequence of generating a stop condition is started by setting "1" to the MST, TRX and PIN, and "0" to the BB. Do not modify the contents of the MST, TRX, BB, PIN until a stop condition is generated on a bus. When a SCL line of bus is pulled down by other devices, the 87CH37/K37/M37 generates a stop condition after they release a SCL line.

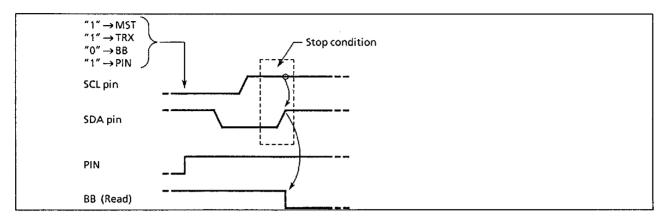

Figure 2-46. Stop Condition Generation

#### (5) Restart

Restart is used to change the direction of data transfer between a master device and a slave device during transferring data. The following explains how to restart when the 87CH37/K37/M37 is in the master mode.

Clear "0" to the MST, TRX and BB, and set "1" to the PIN and release the bus. The SDA pin retains the high-level and the SCL pin is released. Since a stop condition is not generated on a bus, a bus is assumed to be in a busy state from other devices. Check the BB until it becomes "0" to check that the SCL pin of the 87CH37/K37/M37 is released. Check the LRB until it becomes "1" to check that the SCL line on a bus is not pulled down to the low-level by other devices. After confirming that a bus stays in a free state, generate a start condition with procedure 2.9.5. (2).

In order to meet setup time when restarting, take at least 4.7 [ $\mu$ s] of waiting time by software from the time of restarting to confirm that the bus is free until the time to generate the start condition.

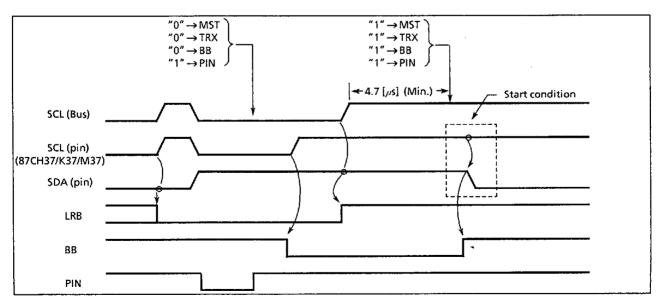

Figure 2-47. Timing Diagram when Restarting the 87CH37/K37/M37

3-37-83

## 2.9.6 Clocked-synchronous 8-bit SIO Mode Control

The following registers are used for control and operation status monitoring when using the serial bus interface (SBI) in the clocked-synchronous 8-bit SIO mode.

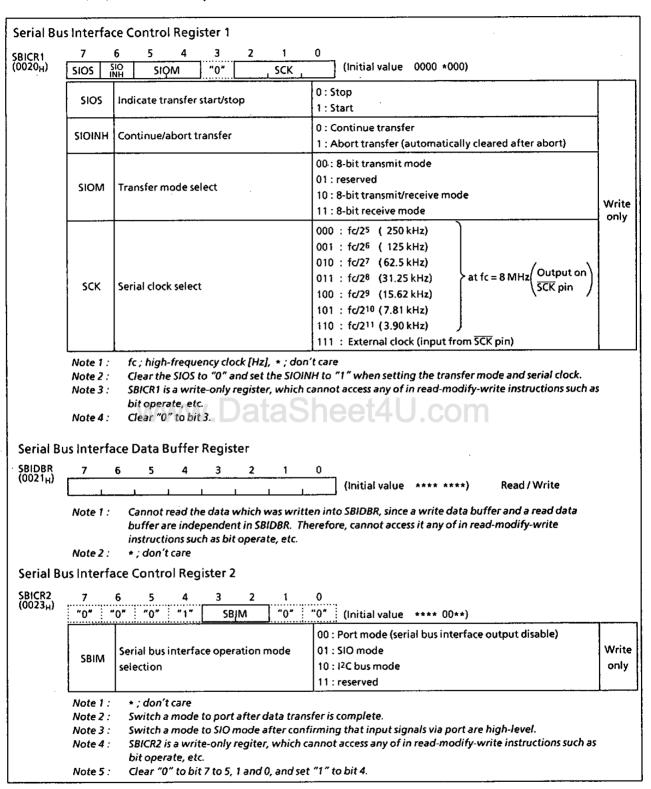

Figure 2-48. Serial Bus Interface Control Register 1 / Serial Bus Interface Data Buffer Register / Serial Bus Interface Control Register 2 in SIO Mode

3-37-84

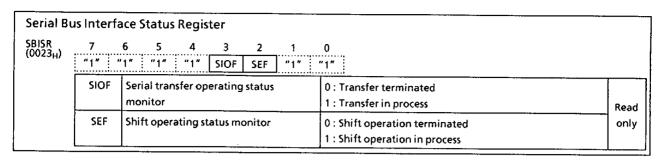

Figure 2-49. Serial Bus Interface Status Register in SIO Mode

#### (1) Serial Clock

## a. Clock source

The SCK (bit 2 to 0 in the SBICR1) is used to select the following functions.

① Internal Clock

In an internal clock mode, any of seven frequencies can be selected. The serial clock is output to the outside on the  $\overline{SCK}$  pin. The  $\overline{SCK}$  pin becomes a high-level when data transfer starts. When writing (in the transmit mode) or reading (in the receive mode) data cannot follow the serial clock rate, an automatic-wait function is executed to stop the serial clock automatically and hold the next shift operation until reading or writing is complete.

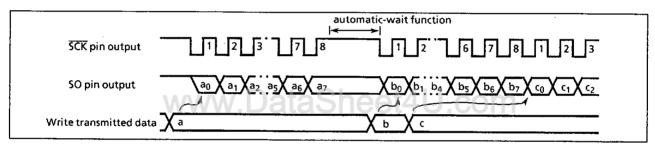

Figure 2-50. Automatic-wait Function

External clock (SCK = "111")

An external clock supplied to the  $\overline{SCK}$  pin is used as the serial clock. In order to ensure shift operation, a pulse width of at least 4 machine cycles is required for both high-level and low-level in the serial clock. The maximum data transfer frequency is 250 kHz (when fc = 8 MHz).

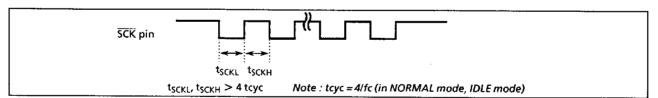

Figure 2-51. Maximum Data Transfer Frequency When External Clock Input

# b.Shift edge

**TOSHIBA** 

The leading edge is used to transmit data, and the trailing edge is used to receive data.

- ① Leading edge shift
  Data is shifted on the leading edge of the serial clock (at a falling edge of the SCK pin input / output).
- ② Trailing edge shift
  Data is shifted on the trailing edge of the serial clock (at a rising edge of the SCK pin input/output).

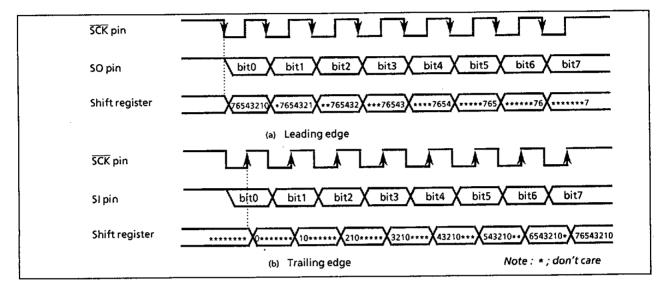

Figure 2-52. Shift Edge

## (2) Transfer mode

The SIOM (bit 5 and 4 in the SBICR1) is used to select a transmit, receive, or transmit/receive mode. a. 8-bit transmit mode

Set a control register to a transmit mode and write transmit data to the SBIDBR.

After the transmit data is written, set the SIOS to "1" to start data transfer. The transmitted data is transferred from the SBIDBR to the shift register and output to the SO pin in synchronous with the serial clock, starting from the least significant bit (LSB). When the transmit data is transferred to the shift register, the SBIDBR becomes empty. The INTSBI (buffer empty) interrupt request is generated to request new data.

When the internal clock is used, the serial clock will stop and automatic-wait function will be initiated if new data is not loaded to the data buffer register after the specified 8-bit data is transmitted. When new transmit data is written, automatic-wait function is canceled.

When the external clock is used, data should be written to the SBIDBR before new data is shifted. The transfer speed is determined by the maximum delay time between the time when an interrupt request is generated and the time when data is written to the SBIDBR by the interrupt service program.

When the transmit is started, after the SIOF goes "1" output from the SO pin holds final bit of the last data until falling edge of the SCK.

Transmitting data is ended by clearing the SIOS to "0" by the buffer empty interrupt service program or setting the SIOINH to "1". When the SIOS is cleared, the transmitted mode ends when all data is output. In order to confirm if data is surely transmitted by the program, set the SIOF (bit 3 in the SBISR) to be sensed. The SIOF is cleared to "0" when transmitting is complete. When the SIOINH is set, transmitting data stops. The SIOF turns "0".

When the external clock is used, it is also necessary to clear the SIOS to "0" before new data is shifted; otherwise, dummy data is transmitted and operation ends.

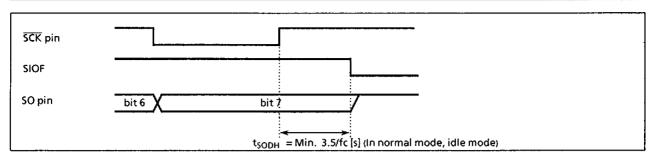

Figure 2-54. Transmitted Data Hold Time at End of Transmit

#### b.8-bit Receive Mode

Set the control register to receive mode and the SIOS to "1" for switching to receive mode. Data is received from the SI pin to the shift register in synchronous with the serial clock, starting from the least significant bit (LSB). When the 8-bit data is received, the data is transferred from the shift register to the SBIDBR. The INTSBI (buffer full) interrupt request is generated to request of reading the received data. The data is then read from the SBIDBR by the interrupt service program.

When the internal clock is used, the serial clock will stop and automatic-wait function will be initiated until the received data is read from the SBIDBR.

When the external clock is used, since shift operation is synchronized with the clock pulse provided externally, the received data should be read from the SBIDBR before next serial clock is input. If the received data is not read, further data to be received is canceled. The maximum transfer speed when the external clock is used is determined by the delay time between the time when an interrupt request is generated and the time when received data is read.

Receiving data is ended by clearing the SIOS to "0" by the buffer full interrupt service program or setting the SIOINH to "1". When the SIOS is cleared, received data is transferred to the SBIDBR in complete blocks. The received mode ends when the transfer is complete. In order to confirm if data is surely received by the program, set the SIOF (bit 3 in the SBIDBR) to be sensed. The SIOF is cleared to "0" when receiving is complete. After confirming that receiving has ended, the last data is read. When the SIOINH is set, receiving data stops. The SIOF turns "0" (the received data becomes invalid, therefore no need to read it).

Note: When the transfer mode is switched, the SBIDBR contents are lost. In case that the mode needs to be switched, receiving data is concluded by clearing the SIOS to "0", read the last data, and then switch the mode.

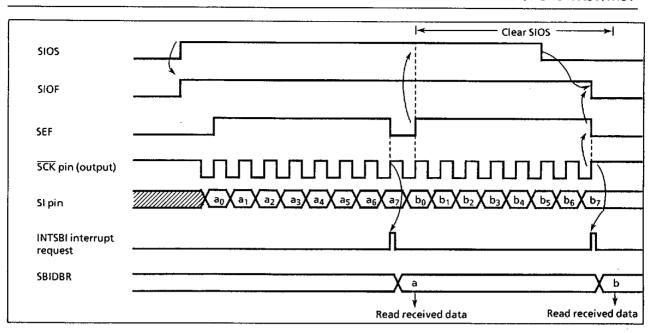

Figure 2-55. Receive Mode (Example: Internal clock)

#### c. 8-bit Transmit / Receive Mode

Set a control register to a transmit / receive mode and write data to the SBIDBR. After the data is written, set the SIOS to "1" to start transmitting / receiving. When transmitting, the data is output from the SO pin on the leading edges in synchronous with the serial clock, starting from the least significant bit (LSB). When receiving, the data is input to the SI pin on the trailing edges of the serial clock. 8-bit data is transferred from the shift register to the SBIDBR, and the INTSBI interrupt request occurs. The interrupt service program reads the received data from the data buffer register and writes data to be transmitted. The SBIDBR is used for both transmitting and receiving. Transmitted data should always be written after received data is read.

When the internal clock is used, automatic-wait function is initiated until received data is read and next data is written.

When the external clock is used, since the shift operation is synchronized with the external clock, received data is read and transmitted data is written before new shift operation is executed. The maximum transfer speed when the external clock is used is determined by the delay time between the time when an interrupt request is generated and the time when received data is read and transmitted data is written.

When the transmit is started, after the SIOF goes "1" output from the SO pin holds final bit of the last data until falling edge of the  $\overline{SCK}$ .

Transmitting / receiving data is ended by clearing the SIOS to "0" by the INTSBI interrupt service program or setting the SIOINH to "1". When the SIOS is cleared, received data is transferred to the SBIDBR in complete blocks. The transmit / receive mode ends when the transfer is complete. In order to confirm if data is surely transmitted / received by the program, set the SIOF (bit3 in the SBISR) to be sensed. The SIOF becomes "0" after transmitting / receiving is complete. When the SIOINH is set, transmitting / receiving data stops. The SIOF turns "0".

Note: When the transfer mode is switched, the SBIDBR contents are lost. In case that the mode needs to be switched, conclude transmitting / receiving data by clearing the SIOS to "0", read the last data, and then switch the transfer mode.

# 2.10 Remote Control Signal Preprocessor / External Interrupt 3 Input Pin

The remote control signal waveform can be determined by inputting the remote control signal waveform from which the carrier wave was eliminated by the receive circuit to P30 (INT3/RXIN) pin. When the remote control signal preprocessor / external interrupt 3 pin is also used as the P30 port, set the P30 port output latch to "1". When it is not used as the remote control signal preprocessor / external interrupt 3 input pin, it can be used for normal port.

## 2.10.1 Configuration

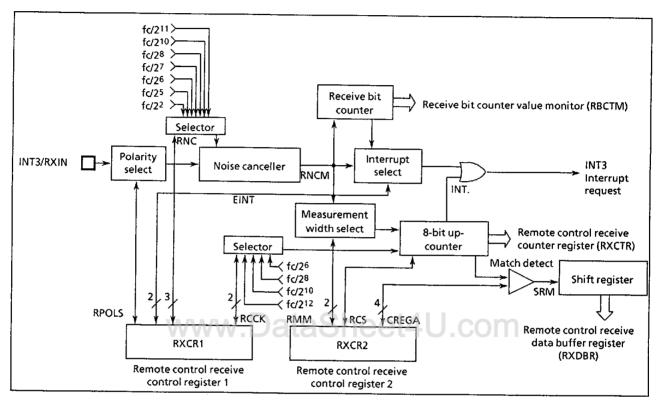

Figure 2-58. Remote Control Signal Preprocessor

# 2.10.2 Remote control signal preprocessor control

When the remote control signal preprocessor is used, operating states are controlled and monitored by the following registers. Interrupt requests also use the remote control signal preprocessor / external interrupt 3 input pin.

- Remote control receive control register 1 (RXCR1)
- Remote control receive control register 2 (RXCR2)
- Remote control receive counter register (RXCTR)
- Remote control receive data buffer register (RXDBR)
- Remote control receive status register (RXSR)

When this pin is used for the external interrupt 3 input, set EINT in RXCR1 to other than "11".

1	11	(2 <sup>14</sup> + 5) / fc	2.049	(2 <sup>11</sup> × 7 – 1) / fc	1.792 [ms]	

#### 2.10.4 Operation

www.DataSheet4U.com

(1) interrupts at rising, falling, or rising / falling edge, and measurement modes
First set EINT and RMM. Next, set RCS to "1"; the 8-bit up-counter is counted up by the internal
clock. After measurement, the 8-bit up-counter value is saved in RXCTR. Then, the 8-bit upcounter is cleared, an INT3 request is generated, and the 8-bit up-counter resumes counting.
If the 8-bit up-counter overflows (FFH) before measurement is completed, an INT3 request is
generated and the overflow flag (OVFF) is set to "1". Then, the 8-bit up-counter is cleared. An
overflow can be detected by reading OVFF by the interrupt processing. To restart the 8-bit up-

Setting RCS to "1" zero-clears OVFF.

counter, set RCS to "1".

## (2) 8-bit receive end interrupts and measurement modes

By determining one-cycle remote control signal or one-pulse width as one-bit data "0" or "1", an INT3 request is generated after 8-bit data is received. When "0" is determined, this means the upper four bits in the 8-bit up-counter have not reached the CREGA value. When "1" is determined, this means the upper four bits in the 8-bit up-counter have reached or exceeded the CREGA value. The 8-bit up-counter value is saved in RXCTR after one bit is determined. The determined data is saved, bit by bit, in RXDBR at the rising edge of the remote control signal (when RPOLS = 1, falling edge). The number of bits saved in RXDBR is counted by the receive bit counter and saved in RBCTM. RBCTM is set to "0001B" at the rising edge of the input (when RPOLS = 1, falling edge) after the INT3 request is generated.

# 2.11 6-bit A/D Conversion (Comparator) Inputs

The comparator input is an analog input to discriminate key input or AFC (Auto Frequency Control) signal input, etc. The analog input voltage level (pins CIN3 to CIN0) can be detected as 64-stage by setting reference voltage.

The comparator input pins CIN3 to CIN0 can also be used as ports P57 to P54.

When used as a comparator input, the output latch should be set to "1".

## 2.11.1 Configuration

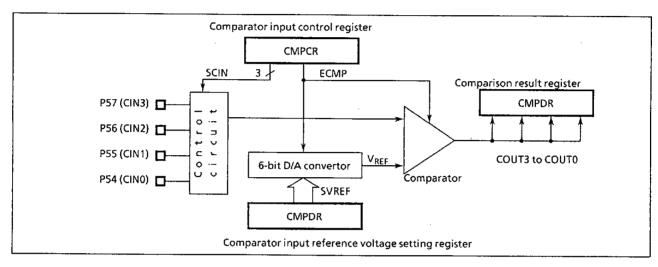

Figure 2-66. 6-bit A/D Conversion (Comparator) Inputs

www.DataSheet4U.com

3-37-101

#### **2.11.2 Control**

A/D conversion (comparator) inputs are controlled by a comparator input control register (CMPCR) and a comparator input data register (CMPDR). The CMPDR contains a reference voltage setting register (write-only) and a comparison result register (read-only).

**MAINTENANCE** 

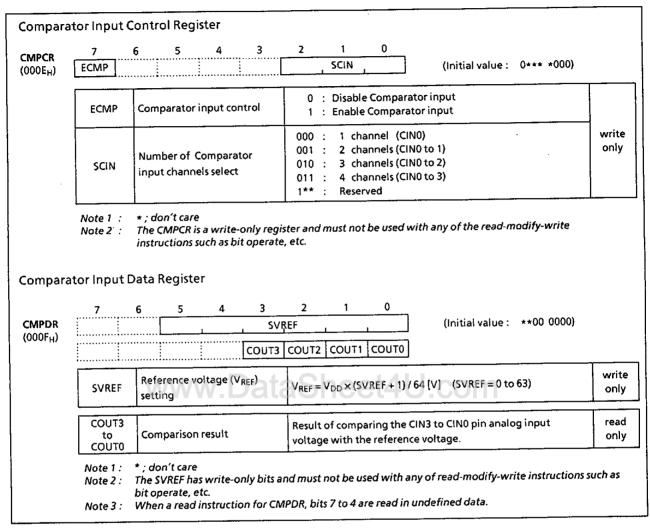

Figure 2-67. Comparator Input Control Register and Data Register

3-37-102

#### **2.11.3** Function

Reference voltage (VREF) is set with SVREF (bits 5 to 0 in CMPDR).

 $V_{REF} = V_{DD} \times (SVREF + 1) / 64 [V] (SVREF = 0 to 63)$ 

The number of comparator input channels is selected with SCIN (bits 2 to 0 in CMPCR). Sequential comparison of the selected number of channels is started by setting ECMP (bit 7 in CMPCR) to "1".

The comparison of one channel requires two machine cycles; therefore, the comparison result register (COUT3 to COUT0) should be read out at an interval equal to [number of channels  $\times$  2 machine cycles] after setting the reference voltage (V<sub>REF</sub>). COUT3 to COUT0 are set to "1" if the input voltage (pins CIN3 to CIN0) is higher than the reference voltage (V<sub>REF</sub>); otherwise those are cleared to "0".

Note 1: When entering STOP mode, ECMP is automatically cleared and SCIN/SVREF are held. And, COUT3 to COUT0 are always set to "1".

Note 2: Any pins specified for comparator input with SCIN can no longer be used for normal digital input and, are read out as "0".

Note 3: COUT3 to COUT0 are read out as "1" when not used as a comparator input. For example, bit 3 in CMPDR is always read out as "1" when SCIN =  $010_B$ .

Example : Comparates the CIN3 to CIN0 inputs with  $V_{REF} = 2.5 \text{ V}$  (at  $V_{DD} = 5 \text{ V}$ ).

## 2.12 Pulse Width Modulation Circuit Output

87CH37/K37/M37 has a 14-bit resolution pulse width modulation (PWM) channel and 9 7-bit resolution PWM channels. D/A converter output can easily be obtained by connecting an external low-pass filter. PWM outputs are multiplexed with general purpose I/O ports as; P40 (PWM0) to P47 (PWM7), P50 (PWM8), P51 (PWM9). When these ports are used as PWM outputs, the corresponding bits of P4, P5 output latches and input/output control latches should be set to "1".

## 2.12.1 Configuration

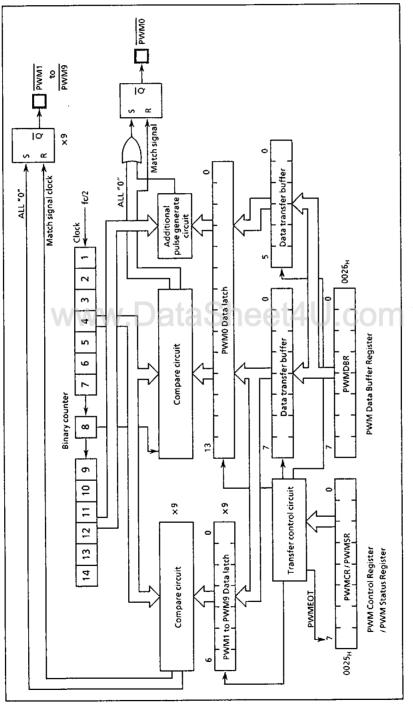

Figure 2-68. Pulse Width Modulation Circuit

3-37-104

## 2.12.2 PWM Output Wave Form

#### (1) PWM0 output

**TOSHIBA** 

This is 14-bit resolution PWM output and one period is  $T_{M} = 2^{15}/f_{C}$  [s].

The 8 high-order bits of the PWM data latch control the pulse width of the pulse output with a period of  $T_S$  ( $T_S = T_M/64$ ), which is the sub-period of the  $\overline{PWM0}$ . When the 8-bit data are decimal n ( $0 \le n \le 255$ ), this pulse width becomes  $n \times t_0$ , where  $t_0 = 2/f_C$ .

The lower 6-bit of 14 bit data are used to control the generation of additional to wide pulse in each  $T_S$  period. When the 6-bit data are decimal m ( $0 \le m \le 63$ ), the additional pulse is generated in each of m periods out of 64 periods contained in a  $T_M$  period. The relationship between the 6 bits data and the position of  $T_S$  period where the additional pulse is generated is shown in Table 2-12.

Table 2-12. Correspondence between 6 Bits Data and the Additional Pulse Generated T<sub>5</sub> Period

Bit position of 6 bits data	Relative position of Ts where the output pulse is generated. (Number i of $T_{S(i)}$ is listed)		
Bit 0	32		
Bit 1	16, 48		
Bit 2	8, 24, 40, 56		
Bit 3	4, 12, 20, 28, 36, 44, 52, 60		
Bit 4	2, 6, 10, 14, 18, 22, 26, 30,, 58, 62		
Bit 5	1, 3, 5, 7, 9, 11, 13, 15, 17,, 59, 61, 63		

Note: When the corresponding bit is "1", it is output.

#### (2) PWM1 to PWM9 outputs

These are 7-bit resolution PWM outputs and one period is  $T_N = 28/\text{fc}$  [s]. When the 7-bit data are decimal k ( $0 \le k \le 127$ ), the pulse width becomes  $k \times t_0$ . The wave form is illustrated in Figure 2-69.

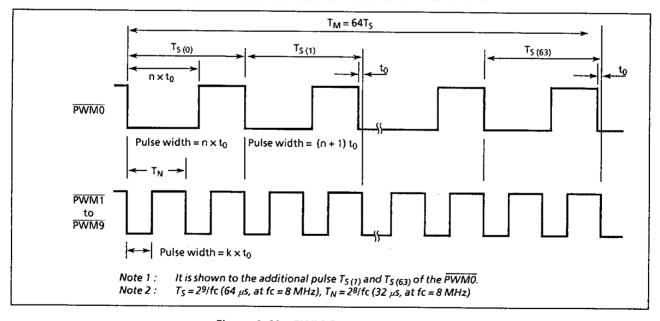

Figure 2-69. PWM Output Wave Form

#### 2.10.3 Control

PWM output is controlled by PWM Control Register (PWMCR) and PWM Data Buffer Register (PWMDBR). The status of transfer PWM data from PWMDBR to PWM data latch is read by PWMEOT of PWM status register (PWMSR).

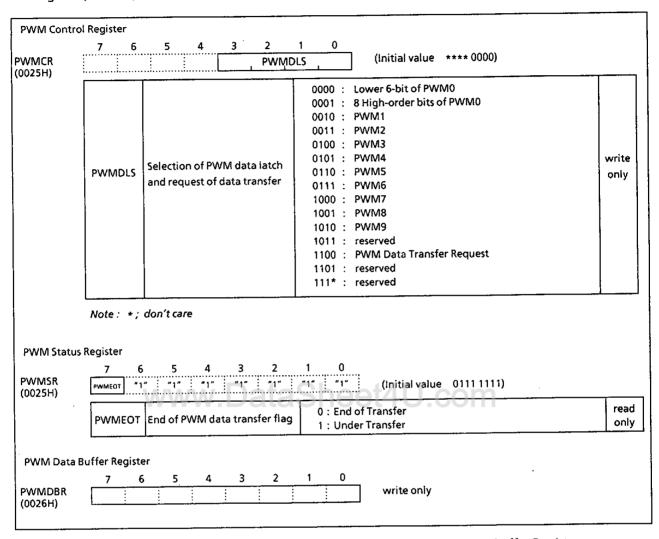

Figure 2-70. PWM Control Register / PWM Status Register / PWM Data Buffer Register

3-37-106

www.DataSheet4U.com

DataSheet4U.com www.DataSheet4U.com

## (1) Programing of PWM Data

PWM output is controlled by writing the output data to data latches. The sequence of writing the output data to data latch is shown as follows;

- 1. Write the channel number of PWM data latch to the PWMDLS.
- 2. Write PWM output data to the PWMDBR.
- 3. Write "0CH" to the PWMCR. When transferring of the output data is completed, the PWMEOT becomes "0", indicating that the next data can be written. Do not write PWM data when the PWMEOT is "1" because write errors can occur in this case.

Note: When writing the output data to PWM0 data latch, write "0CH" to the PWMCR after writing of the 14-bit output data is completed.

While the output data are being written to the data latch, the previously written data are being output. The maximum time from the point at which "0CH" is written to the data latch until PWM output is switched is  $2^{15}$ /fc [s] (4.096 ms, at fc = 8 MHz) for PWM0 output and  $2^{9}$ /fc [s] (64  $\mu$ s, at fc = 8 MHz) for PWM1 to PWM9 output.

Example :  $\overline{\text{PWM0}}$  pin outputs a PWM wave form with a low level of 32  $\mu$ s width and no additional pulse.

 $\overline{PWM1}$  pin outputs a PWM wave form with a low level of 16  $\mu$ s width.  $\overline{PWM2}$  pin outputs a PWM wave form with a low level of 8  $\mu$ s width.

Note: at fc = 8 MHz

## 2.14.2 Character ROM and Display Memory

## (1) Character ROM

**TOSHIBA** 

www.DataSheet4U.com

The character ROM contains 128 character fonts. The user can set fonts as desired. The character ROM consists of 128 characters in 14 x 18 dots (character codes 00<sub>H</sub> to 7F<sub>H</sub>). Each dot corresponds to one bit in the character ROM. When a bit in the character ROM is set to "1", the corresponding dot is displayed; if set to "0", the dot is not displayed. The start address in the character ROM corresponding to a character code is determined by the following expression:

Start address in character ROM =  $CRA \times 40_H + 4000_H$ 

Since character code 00H is used as blank character, the character font for this character code cannot be changed. Write "0" in the data of character code 00H.

Set all unused bits (bit 7 with 0<sub>H</sub> to 8<sub>H</sub> in the lower 4-bit of an address) to "1" and write the data "FFH" to all unused address (the lower 4-bit of an address are 9H to FH) in character ROM.

Figure 2-73. (a) shows an example of the character font configuration for the character code  $00_{\rm H}$  and 01<sub>H</sub>, together with the ROM addresses and data.

Figure 2-73. (b) shows the character ROM dump list for these 2 character fonts.

Note 1: CRA; Character code (00H to 7FH)

Note 2: A data can not be read from the character ROM by software.

Note 3: When ordering a mask, load the data to character ROM at addresses 4000H to 5FFFH.

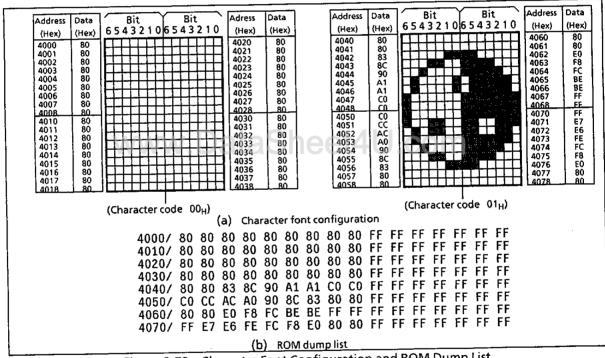

Figure 2-73. Character Font Configuration and ROM Dump List

#### (2) Display memory

Each character out of the 288 characters displayed in 24 characters x 12 rows consists of 13 bits in the display memory. Five data items are written to the display memory: character code, color data, blinking specification, reverse specification, and reverse blinking specification. The display memory contents become unstable after the reset operation is released.

There are two modes for writing display data to the display memory. One mode is for writing all display data (character code, color data, blinking specification, reverse specification, and reverse blinking specification) simultaneously. The other mode is for changing either character code or character ornamentation data (color data, blinking specification, reverse specification, and reverse blinking specification). How the display data is written to the display memory is described in section 2.14.3 (18).

Figure 2-75. Display Memory Address Configuration

## 2.14.3 OSD circuit control

The OSD circuit is controlled by using the OSD control registers assigned to addresses 0F80<sub>H</sub> to 0F9A<sub>H</sub> in the data buffer register (DBR). For write to or read from the OSD control registers, see section 2.14.3 (19). The OSD control registers are used to set display start position, display character ornamentations (that is, fringing, smoothing, color data, character size, and etc.), display memory addresses, character codes, and etc.

After all settings are complete, setting the display on-off control bit, EDISP (bit 0 in ORDON) to "1" enables display (starts display). Setting EDISP to "0" disables display (halts display).

Note: The contents of OSD control registers are not initialized in STOP mode.

#### (1) Display position

The horizontal display start position can be set in 128 steps. The vertical display start positions can be specified for each line using 256 steps. The horizontal display start position is set with OSD control registers HS16 to HS10 (bit 6 to 0 in ORHS1). The vertical display start position of the line 1 is set with VS17 to VS10 (in ORVS1). The vertical display start position of the line 2 to 12 are determined by setting VS27 to VS20 ... VS127 to VS120 (ORVS2 to ORVS12) in the same way.

3-37-111

**MAINTENANCE** 

Horizontal display start position

Specification unit: Display page

Specification steps: 128

Specification horizontal display start position: Line 1 to 12: HS16 to HS10

When FORS is "0" (Normal mode)

 $HS1 = (HS16 \text{ to } HS10) \text{ H} \times 2T_{OSC} + 10T_{OSC} \text{ (Line1 to 12)}$ 

When FORS is "1" (Double frequency mode)

 $HS1 = (HS16 \text{ to } HS10) \text{ H} \times 2T_{OSC} + 6T_{OSC} \text{ (Line1 to 12)}$ 

Note: Tosc; One cycle of OSC oscillation

Vertical display start position

When VDSMD is "0" (Normal mode)

Line n :  $VSn = (VSn7 \text{ to } VSn0)_{H} \times 2T_{HD}$ 

(n; 1 to 12)

When VDSMD is "1" (Double scan mode)

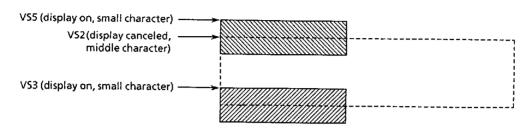

Line n :  $VSn = (VSn7 \text{ to } VSn0)_{H \times 4T_{HD}}$ 

(n; 1 to 12)

Note1: THD; One cycle of HD signal

Note2: If display lines are overlapped each other, previous display line is enabled and next line is

disabled. Set the vertical display start position not to overlap display lines.

Occasion of overlapping

Note3: The line which is displayed off is managed as a small size character line. It is recommendable that its vertical display start position should be set out of TV screen.

Note4: Transfer the contents of vertical display start position registers into OSD circuit before the position of the scanning line coincides with their own vertical display start position

## (2) Double scan mode

The double scan mode is used to handle non-interlaced scanning TV. When double scan mode is enabled, the vertical display counter increases every 4 scan lines and a vertical dot size is double. This function is enabled by setting VDSMD (bit 3 in ORETC) in the OSD control register to "1".

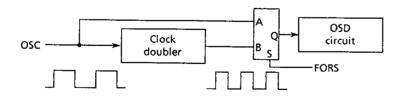

Scan mode select register (1 bit) ... VDSMD (bit 3 in ORETC)

"0" ··· Normal mode

"1" ··· Double scan mode

#### (3) Double frequency mode

The double frequency mode is used to display OSD by the OSC frequency doubled. When this function is enabled, the clock which is doubled by a clock doubler is inputted into an OSD circuit.

This function is ebabled by setting FORS (bit 4 in ORDON) in the OSD control register to "1".

OSC frequency select register (1 bit) ··· FORS (bit 4 in ORDON)

"0" ··· Normal mode

"1" ... Double frequency mode

## (4) Character sizes and display on / off

Character size can be selected line by line from 3 sizes. And display on / off also can be set line by line. Small, middle and large character size and display on / off can be set with OSD control registers CS11, CS10...CS121, CS120 (ORCS4, ORCS8, and ORCS12) in the OSD control registers.

Character sizes : 3 sizes (Small, middle and large)
Character size and display on / off specification unit : Line

Note:  $T_{OSC}$ ; One cycle of OSC oscillation  $T_{HD}$ ; One cycle of  $\overline{HD}$  signal

### (5) Smoothing function

**TOSHIBA** 

The smoothing function is used to make characters look smooth. Enabling smoothing displays 1/4 dot between two dots connecting corner to corner within a character. Small size character can not be enabled smoothing. Smoothing is enabled by setting ESMZ (bit 4 in ORETC) in the OSD control register to "1".

Smoothing specification unit: Display page

Smoothing specification register (1 bit) ... ESMZ (bit 4 in ORETC)

"0" ··· Disable smoothing 
"1" ··· Enable smoothing

### (6) Fringing function

The fringing function is used to display a character with a fringe width is 1/2 dot in a different color from that of the character. For small characters, fringe width is 1 dot. When a character is displayed with the maximum of 14 vertical dots and 18 horizontal dots, the fringe exceeds right and left, top, and bottom of the character display area. The exceeded fringe can be displayed; however, display characters have higher priority to fringe horizontally.

Fringing is enabled for each line by setting EFR1 to EFR12 (OREFR and bit 3 to 0 in ORP6DS) in the OSD control register to "1".

A color for fringe is specified common to all lines using OSD control registers, RFDT, GFDT, and BFDT, (bit 2 to 0 in ORBK).

Fringing specification unit: Line

Fringing enable register (1 bit x 12) ... EFRn (n: 1 to 12) (OREFR and bit 3 to 0 in ORP6DS)

"0" ... Disable fringing
"1" ... Enable fringing

Fringe color specification unit: Display page

Fringe color register (3 bits) ... RFDT, GFDT, BFDT (bit 2 to 0 in ORBK)

Note: When a display line is enabled fringing function, its vertical size is increased by one dot (by two dots when its character size is small) independent of its character font. Therefore, when a vertical display start position is specified to no space between the lines, the display line which is overlapped with increasing dot (s) is canceled.

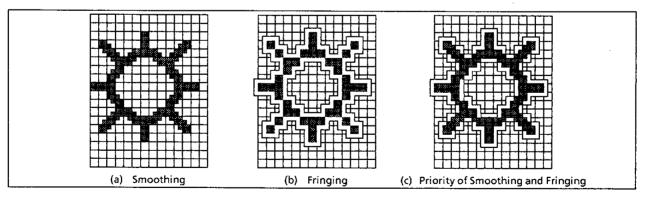

Figure 2-77. Smoothing / Fringing / Priority of Smoothing and Fringing

## (7) Background color function

Background color function is used to color the entire background for the character area ( $14 \times 18$  dots). Except the character area whose character code is  $00_{\rm H}$ .

This function is specified for each display page by setting EBKGD (bit 7 in ORBK) in the OSD control register to "1".

A background color is specified for each display page by setting RBDT, GBDT, and BBDT (bit 5 to 3 in ORBK) in the OSD control registers. A color specification is same as them for full-raster blanking.

Background specification unit: Display page
Background enable register (1 bit) ... EBKGD (bit 7 in ORBK)

"0" ... Disable background
"1" ... Enable background

Background color specification unit: Display page
Background color specification registers (3 bits) --- RBDT, GBDT, BBDT (bit 5 to 3 in ORBK)

Note: When the background color function is used, the blank character (Code 00<sub>H</sub>) can not be used as the first character on the fringing line.

### (8) Full-raster blanking function

Full-raster blanking function is used to color the entire background for the display area (TV screen). When using the full-raster blanking function, set YBLCS (bit7 in ORETC) to "1", output BL signal from Y/BL pin, because Y signal cannot delete whole display page from video signal.

This function is specified for each display page by setting EXBL (bit 6 in ORBK) in the OSD register to "1". Color specification is same as them for background color.

Full-raster blanking specification unit: Display page

Full-raster blanking enable register (1 bit) ... EXBL (bit 6 in ORBK)

"0" ··· Disable full-raster blanking

"1" ... Enable full-raster blanking

Full-raster blanking color specification registers (3 bits) ... RBDT, GBDT, BBDT (bit 5 to 3 in ORBK)

## (9) Reverse function

This function is used to reverse the background and character colors. However, when fringing is specified, the fringe color does not change. If background function is not used, background color is black.

Reverse function is enabled by setting RVF (bit 4 in ORDSN) in the OSD control register to "1".

Reverse specification: Character

Reverse enable register (1 bit) ... RVF (bit 4 in ORDSN)

"0" ... Disable reverse "1" ... Enable reverse

#### . . .

**TOSHIBA** 

### (10) Reverse blinking function

Reverse blinking function is used to reverse the background and character colors.

When RBMF is "1", characters specified for blinking by RBF are reversed the background and character colors. However, when fringing is specified, the fringe color does not change. If background function is not used, background color is black.

Reverse blinking specification unit: Character

Reverse blinking specification register (1 bit) ... RBF (bit 5 in ORDSN)

"0" ... No reverse blinking

"1" ··· Reverse blinking

Reverse blinking master specification register (1 bit) ... RBMF (bit 5 in ORETC)

"0" ... Disable reverse blinking

"1" ... Enable reverse blinking

(Characters whose RBF is set to "1" are reversed the background and character colors.)

Table 2-15. Display Mode

RBF	RVF	RBMF	Display
0	0	*	Normal
0	1	*	Reverse
1	^	0	Normal
<b>1</b>	U 0	1	Reverse
1	1	*	reserved

<sup>\*;</sup> don't care

# (11) Blinking function

Blinking function is used to blink display characters.

When BKMF is "1", characters specified for blinking by BLF are not displayed. (If the background color function is used, the background color is not disappeared.)

Blinking specification unit: Character

Blinking specification register (1 bit) ... BLF (bit 3 in ORDSN)

"0" ··· No blinking

"1" --- Blinking

Blinking master specification register (1 bit) ... BKMF (bit 6 in ORETC)

"0" ... Disable blinking

"1" ... Enable blinking (Characters whose BLF are set to "1" are not displayed.)

#### (12) Character

Characters: 128 (including blank character)

Character specification register (7 bits) ... CRA6 to CRA0 (bit 6 to 0 in ORCRA)

Character code "00H" ... Blank character

Character code "01<sub>H</sub>" to "7F<sub>H</sub>" ... User programmable by character ROM

### (13) Character color

TOSHIBA

Character colors: 8

Character color specification unit: Character

Character color specification register (3 bits) ··· RDT / GDT / BDT (bit 2 to 0 in ORDSN)

Table 2-16. Character Color

RDT	GDT	BDT	Character Color
0	0	0	Black
0	0	1	Blue
0	1	0	Green
0	1	1	Cyan
1	0	0	Red
1	0	1	Magenta
1	1	0	Yellow
1	1	1	White

### (14) OSD interrupt

#### 1) Display line counter

The display line counter indicates number of display line(s) by OSD circuit on the TV screen. The display line counter is a 4-bit counter which is initialized to "0" by the falling edge of the  $\overline{VD}$  signal and which increments when last scanning of each display line is completed (falling edge of the  $\overline{HD}$  signal). It is necessary to be read out display line counter several times, because it does not synchronize CPU clock.

Display line counter register (4 bits) ··· DCTR (bit 3 to 0 in ORIRC)

"0000" ··· No display line is completed.

"0001" ··· 1'st display line is completed.

"0010" ··· 2'nd display line is completed.

to

"1111" ··· 15'th display line is completed.

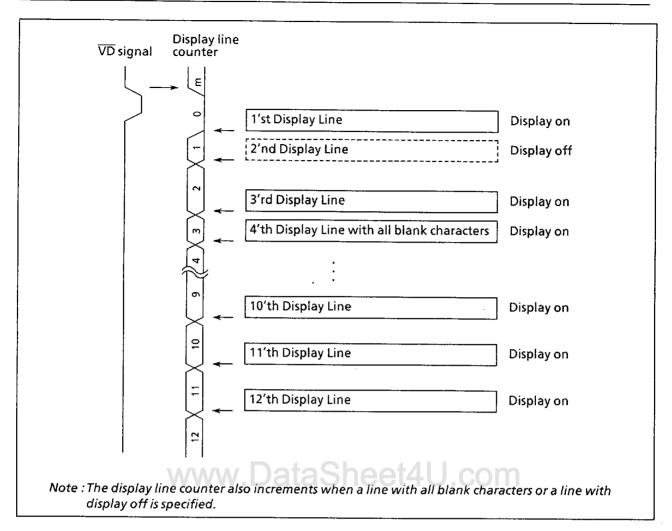

Figure 2-78. Display Line Counter

#### 2) Interrupt generator circuit

An interrupt request is generated when a falling edge of  $\overline{VD}$  signal or when line counter (DCTR) is counted to the certain value specified by ISDC.

Interrupt souce select register (1 bit) ... SVD (bit4 in ORIRC)

"0" ... Interrupt request generated when the display line counter (DCTR) is counted to the certain value which is specified by ISDC.

"1" ... Interrupt request is generated when a falling edge of  $\overline{VD}$  signal.

Interrupt generation line specification register (4 bits) ... ISDC (bit 3 to 0 in ORIRC)

"0000" ... Interrupt request generated when the display line counter is cleared.

"0001" ··· Interrupt request generated at end points of the last scanning line of the first displey line

"0010" ... Interrupt request generated at end points of the last scanning line of the 2'nd display line

to

"1111" ··· Interrupt request generated at end points of the last scanning line of the 15'th display line

3-37-119

## (15) P6 port output select function

This function is used to select whether the contents of port P67 to P64 will be output or R, G, B, Y/BL signals of the OSD circuit will be output on pins P67 to P64.

P6 port output select registers (4 bits) ... P67DS to P64DS (bit 7 to 4 in ORP6DS)

"1" ... R, G, B, Y/BL signal output

"0" ... Port contents output

### (16) OSD pin output polarity control function

This function is used to select the polarity of the OSD outputs for RGB and Y/BL.

Output polarity control register (3 bits) ··· BLIV, YIV, RGBIV (bit 7 to 5 in ORIRC)

Table 2-17. Control of OSD Output Polarity

Symbol	Output port	Data "0"	Data "1"
BLIV	BL	Active High	Active Low
YIV	Y	Active High	Active Low
RGBIV	RGB	Active High	Active Low

#### (17) Y/BL signal select function

This function is used to select either Y or BL signal output from the Y/BL pin.

Y/BL signal select register (1 bit) ... YBLCS (bit 7 in ORETC)

"0" ... Y signal output

"1" ··· BL signal output

Y signal ... Logical OR for R, G, B Character data, and Fringing data.

BL signal ... When EXBL is "0":

Output in all display character areas

(except for character code 00H: blank character)

When EXBL is "1":

Output in the whole page

#### (18) Writing display data to the display memory

Data are written to the display memory using DMA8 to DMA0, CRA6 to CRA0, RDT, GDT, BDT, BLF, RBF, RVF, and MBK registers.

Display memory address specification register (9 bits) ···

DMA8 to DMA0 (bit0 in ORETC and ORDMA)

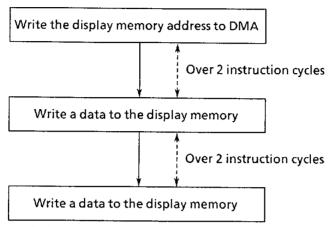

Display memory bank switching register (1 bit) ··· MBK (bit1 in ORETC)

"0" ··· For changing either character code or character ornamentation

"1" ··· For changing both character code and character ornamentation

Note 1: Don't use the 2 bytes transfer operation such as [LDW (HL), mn] when accessing to display memory.

Note 2: When writing a data to the display memory immediately after setting the display memory address to DMA, or when continuously writing a data to the display memory, insert over 2 instruction cycles between the instrunction for writing a data.

Example: Setting a character code ( $20_H$ ) to the display memory (Address :  $120_H$  to  $121_H$ )

LD HL, ORCRA ; Set ORCRA address to HL req. LD A, 20H ; Load character code to A reg. LD DE, ORDMA ; Set lower 8-bit addresses to DMA7 to 0 LD (DE), 20H LD DE, ORETC ; Set the most upper address to DMA8 and set MBK to "0" LD (DE), 00000001B LD DE, ORDMA ; Set lower 8-bit addresses to DMA7 to 0 LD (DE), 20H LD DE, ORETC ; Set the most upper address to DMA8 and set MBK to "0" LD (DE), 00000001B NOP ; Insert 2 instruction cycles NOP LD (HL),A; Write a character code to display memory (Address: 120H) NOP ; Insert 2 instruction cycles NOP LD (HL),A; Write a character code to display memory (Address: 121H)

Note 3: Transfer the contents of display memory which affect displaying characters into OSD circuit, before the position of scanning line coincides with their own vertical display start position.

3-37-121

- a. Display memory write sequence when writing both character code and character ornamentation.
  - ① Write lower 8-bit addresses of display memory to DMA7 to DMA0 (in ORDMA).
  - Write the most upper addresses of display memory to DMA8 (bit 0 in ORETC) and set MBK (bit 1 in ORETC) to "1".

Note: It is necessary to write all bits of display memory address, writting DMA8 after DMA7 to DMA0, when writing display address, and repeat this sequence.

- Write character ornamentation data (blinking, reverse, reverse blinking, and color data) to RDT, GDT, BDT, BLF, RVF, and RBF.
  At this time, the character ornamentation data is transferred to the display memory.
- Write character code to CRA6 to CRA0. At this time, character code is transferred to the display memory together with the character ornamentation data which is written in ③ and DMA8 to DMA0 are automatically incremented.
- b. Display memory write sequence when writing either character code or character ornamentation
  - ① Write lower 8-bit addresses of display memory to DMA7 to DMA0 (in ORDMA).
  - Write the most upper address of display memory to DMA8 (bit 0 in ORETC) and clear MBK (bit 1 in ORETC) to "0".

Note: It is necessary to write all bits of display memory address, writting DMA8 after DMA7 to DMA0, when writing display address, and repeat this sequence.

Write character ornamentation data (blinking, reverse, reverse blinking, and color data) to RDT, GDT, BDT, BLF, RVF, and RBF or write character code to CRA6 to CRA0. At this time, written data are transferred to the display memory and DMA8 to DMA0 are automatically incremented.

## (19) OSD control register write / read

The address of the OSD control registers are assigned to the DBR area.

To write or to read from the OSD control registers, the method is the same as for accessing ordinary DBR registers.

The written data are transferred to the OSD circuit at the end point of the scanning line without display by setting RGWR register to "1" and become valid. And, be able to write value of OSD control register after RGWR flag is cleared to "0".

- Note 1: Do not write the contents of OSD control registers during RGWR flag is "1". If contents of OSD control registers are written during RGWR flag is "1", the written data are broken.
- Note 2: Do not clear RGWR register to "0". If RGWR register is cleared to "0", the contents of OSD control registers may be transferred to OSD circuit at unexpected timing.
- Note 3: Insert over 3 instruction cycles between the instruction which sets RGWR register to "1" and the instruction which checks RGWR flag.
- Note 4: Transfer the contents of all OSD control registers which affect displaying characters into OSD circuit before the position of scanning line coincides with their own vertical display start position.

Example 1: In the case of writing the data into OSD registers, setting RGWR register to "1" and checking RGWR flag

```
Writing the data into OSD registers
             LD
                    A, (TEMP_ORDON)
                                           ; Set bit 2 of work-area to "1"
             SET
             LD
                    HL, ORDON
                                             Set RGWR register to "1" (Request data transfer)
             LD
                    (HL), A
             NOP
                                           ; Insert 3 instruction cycles
             NOP
             NOP
CHECK RGWR FLAG:
             TEST
                    (HL).2
                                           ; Check RGWR flag until RGWR flag is "0"
             JR
                    F, CHECK RGWR FLAG
```

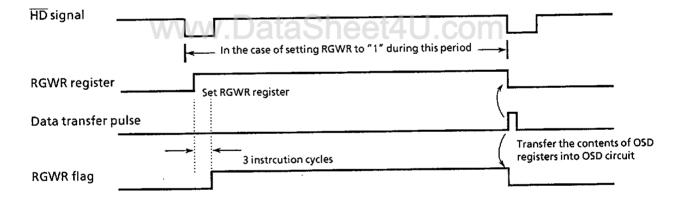

Example 2: In the case of checking RGWR flag, writing the data into OSD registers, and writing RGWR register to "1"

```
HL, ORDON
             LD
CHECK RGWR_ FLAG:
                                           ; Checking RGWR flag until RGWR flag is "0"
             TEST
                    (HL).2
                    F, CHECK RGWR FLAG
             JR
            Writing the data into OSD registers
                    A, (TEMP_ORDON)
                                           ; Set bit 2 of work-area to "1"
             LD
             SET
                                           ; Set RGWR register to "1" (Request data transfer)
             LD
                    HL, ORDON
             LD
                     (HL), A
                                           ; Insert 3 instruction cycles
             NOP
             NOP
             NOP
```

The timing chart of transferring the contents of OSD registers into OSD circuit is shown as follows;

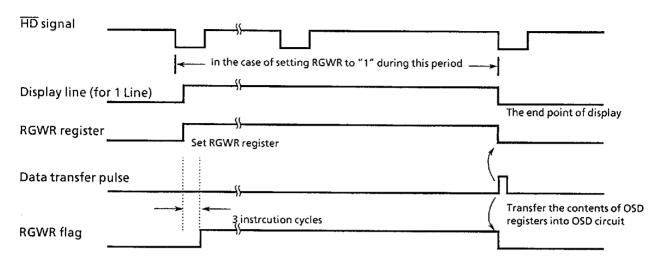

1. In the case of setting RGWR register to "1" during the position of the scanning line is in no display area (except any lines specified as display off by CSn).

The contents of OSD registers are transferred into OSD circuit when the position of the scanning line is at the falling edge of HD signal.

2. In the case of setting RGWR register to "1" during the position of the scanning line is in display area (including any lines specified as display off by CSn).

The contents of OSD registers are transferred into OSD circuit when the position of the scanning line is at the falling edge of  $\overline{\text{HD}}$  signal of finishing the display line.

For registers (DMA8 to DMA0, CRA6 to CAR0, RDT, GDT, BDT, BLF, RBF, RVF, MBK) used for updating the display memory, P67DS to P64DS, YBLCS, BKMF, RBMF, ESMZ, VDSMD, FORS, and RGWR, the data become valid as soon as they are written.

Written data transfer register (1 bit) ... RGWR (bit 2 in ORDON)

"0" ··· Initial state

"1" ··· Transfer written data to OSD circuit. (After transfer, RGWR register and RGWR flag are automatically cleared to "0".)

Written data transfer monitor flag (1 bit) ... RGWR (bit 2 in ORDON)

"0" ··· Transfer completed.

"1" ··· During transfer

#### (20) Display on / off

This function is used to display characters specified for on / off display.

Display on / off specification unit: Display page

Display on / off specification register (1 bit) ... EDISP (bit 0 in ORDON)

"0" ... Disable display
"1" ... Enable display

Note: Do not start STOP mode during display is enabled.

## (21) Window function

This function is used to set upper and lower limit of display page. Window upper limit is specified by WVSH (ORWVSH). Window lower limit is specified by WVSL (ORWVSL). This function is enabled by setting EWDW (bit 1 in ORDON) in the OSD control register to "1".

Window specification unit: Display page

Window function enable specification register (1 bit) ... EWDW (bit 1 in ORDON)

"0" ··· Disable window function
"1" ··· Enable window function

Window upper limit specification register (8 bits) ... WVSH7 to 0 (ORWVSH) Window lower limit specification register (8 bits) ... WVSL7 to 0 (ORWVSL)

Window upper and lower limit position ...

When VDSMD is "0" (Normal mode):

WVSH = (WVSH7 to WVSH0)  $_{H} \times 2T_{HD}$ WVSL = (WVSL7 to WVSL0)  $_{H} \times 2T_{HD}$ 

When VDSMD is "1" (Double scan mode):

WVSH = (WVSH7 to WVSH0)  $_{H} \times 4T_{HD}$ WVSL = (WVSL7 to WVSL0)  $_{H} \times 4T_{HD}$ 

Note 1: THD; One cycle of HD signal

Note 2: WVSL > WVSH≥ "1"

Note 3: Modify the value of window upper and lower limit register as follows:

1. When WVSH<sub>NEW</sub> ≤ WVSH<sub>OLD</sub>

Set the new value, during  $\overline{\text{VD}}$  signal is low or before the position of the scanning line coincides with WVSH<sub>NEW</sub>.

2. When WVSL > WVSH<sub>NEW</sub> > WVSH<sub>OLD</sub>

Set the new value, during  $\overline{\text{VD}}$  signal is low or before the position of the scanning line coincides with WVSHOLD.

3. When WVSL<sub>NEW</sub> ≤ WVSL<sub>OLD</sub>

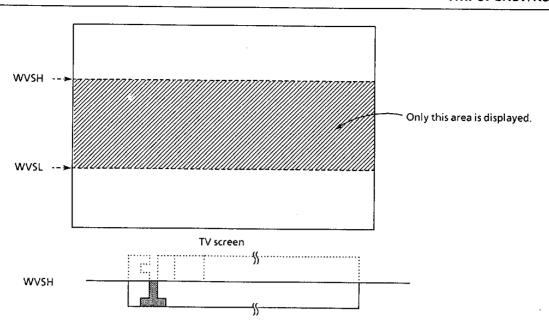

Set the new value, during  $\overline{\text{VD}}$  signal is low or before the position of the scanning line coincides with WVSL<sub>NEW</sub>.

4. When WVSLNEW > WVSLOLD

Set the new value, during  $\overline{\text{VD}}$  signal is low or before the position of the scanning line coincides with WVSLOLD.

Note 4: It is recommendable that the window function is always enabled (EWDW = "1") and set WVSH to "01H", WVSL to "FEH". When the window function should be set to disable, clear EWDW to "0" independent of the value which this register has been set from detecting the rising edge of  $\overline{\text{HD}}$  signal by software until the falling edge of  $\overline{\text{HD}}$  signal.

9097249 0036657 T87 📟

## (22)OSD Control Registers

Can not access all OSD control registers in any of read-modify-write instructions such as bit operation, etc.
