Functional Description

The CY62138FV30 is a high performance CMOS static RAM organized as 256K words by 8 bits. This device features advanced circuit design to provide ultra low active current. This is ideal for providing More Battery Life™ (MoBL[®]) in portable applications such as cellular telephones. The device also has an automatic power down feature that significantly reduces power consumption. Place the device into standby mode reducing power consumption when deselected (\overline{CE}_1 HIGH or CE_2 LOW).

To write to the device, take Chip Enable (\overline{CE}_1 LOW and CE_2 HIGH) and Write Enable (\overline{WE}) inputs LOW. Data on the eight I/O pins (I/O₀ through I/O₇) is then written into the location specified on the address pins (A₀ through A₁₇).

To read from the device, take Chip Enable (\overline{CE}_1 LOW and CE_2 HIGH) and Output Enable (\overline{OE}) LOW while forcing Write Enable (\overline{WE}) HIGH. Under these conditions, the contents of the memory location specified by the address pins appear on the I/O pins.

The eight input and output pins (I/O₀ through I/O₇) are placed in a high impedance state when the device is deselected (\overline{CE}_1 HIGH or CE_2 LOW), the outputs are disabled (\overline{OE} HIGH), or during a write operation (\overline{CE}_1 LOW and CE_2 HIGH and \overline{WE} LOW).

Notes

14. In an earlier revision of this device, under a specific application condition, READ and WRITE operations were limited to switching of the chip enable signal as described in the Application Note AN66311. However, the issue has been fixed and in production now, and hence, this Application Notes is no longer applicable. It is available for download on our website as it contains information on the date code of the parts, beyond which the fix has been in production.
15. Test conditions for all parameters other than tristate parameters assume signal transition time of 3 ns or less (1 V/ns), timing reference levels of $V_{CC(typ)}/2$, input pulse levels of 0 to $V_{CC(typ)}$, and output loading of the specified I_{OL}/I_{OH} as shown in the AC Test Loads and Waveforms on page 5.
16. At any given temperature and voltage condition, t_{HZCE} is less than t_{LZCE} , t_{HZOE} is less than t_{LZOE} , and t_{HZWE} is less than t_{LZWE} for any given device.
17. t_{HZOE} , t_{HZCE} , and t_{HZWE} transitions are measured when the output enters a high impedance state.
18. The internal write time of the memory is defined by the overlap of \overline{WE} , $CE_1 = V_{IL}$, and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. Reference the data input setup and hold timing to the edge of the signal that terminates the write.
19. The minimum write pulse width for Write Cycle No. 3 (\overline{WE} controlled, \overline{OE} LOW) should be the sum of t_{HZWE} and t_{SD} .

Figure 9. Write Cycle No. 1 ($\overline{\text{WE}}$ Controlled) [23, 24, 25, 26]

Notes

20. The device is continuously selected. $\overline{\text{OE}}$, $\overline{\text{CE}}_1 = V_{\text{IL}}$, $\text{CE}_2 = V_{\text{IH}}$.
21. WE is HIGH for read cycle.
22. Address valid before or similar to $\overline{\text{CE}}_1$ transition LOW and CE_2 transition HIGH.
23. CE is the logical combination of $\overline{\text{CE}}_1$ and CE_2 . When $\overline{\text{CE}}_1$ is LOW and CE_2 is HIGH, $\overline{\text{CE}}$ is LOW; when $\overline{\text{CE}}_1$ is HIGH or CE_2 is LOW, $\overline{\text{CE}}$ is HIGH.
24. The internal write time of the memory is defined by the overlap of WE, $\overline{\text{CE}}_1 = V_{\text{IL}}$, and $\text{CE}_2 = V_{\text{IH}}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. Reference the data input setup and hold timing to the edge of the signal that terminates the write.
25. Data I/O is high impedance if $\overline{\text{OE}} = V_{\text{IH}}$.
26. If $\overline{\text{CE}}_1$ goes HIGH or CE_2 goes LOW simultaneously with $\overline{\text{WE}}$ HIGH, the output remains in high impedance state.
27. During this period, the I/Os are in output state. Do not apply input signals.

Figure 11. Write Cycle No. 3 (\overline{WE} Controlled, \overline{OE} LOW) [28, 31, 33]

Notes

28. \overline{CE} is the logical combination of \overline{CE}_1 and CE_2 . When \overline{CE}_1 is LOW and CE_2 is HIGH, \overline{CE} is LOW; when \overline{CE}_1 is HIGH or CE_2 is LOW, \overline{CE} is HIGH.
29. The internal write time of the memory is defined by the overlap of \overline{WE} , $\overline{CE}_1 = V_{IL}$, and $CE_2 = V_{IH}$. All signals must be ACTIVE to initiate a write and any of these signals can terminate a write by going INACTIVE. Reference the data input setup and hold timing to the edge of the signal that terminates the write.
30. Data I/O is high impedance if $\overline{OE} = V_{IH}$.
31. If \overline{CE}_1 goes HIGH or CE_2 goes LOW simultaneously with \overline{WE} HIGH, the output remains in high impedance state.
32. During this period, the I/Os are in output state. Do not apply input signals.
33. The minimum write pulse width for Write Cycle No. 2 (\overline{WE} controlled, \overline{OE} LOW) should be the sum of t_{HZWE} and t_{SD} .
