

## TEA1062N/TEA1062AN

### LINEAR INTEGRATED CIRCUIT

## LOW VOLTAGE TELEPHONE TRANSMISSION CIRCUIT WITH DIALLER INTERFACE

### DESCRIPTION

The UTC **TEA1062N/TEA1062AN** is a bipolar integrated circuit performing all speech and line interface function, required in the fully electronic telephone sets. It performs electronic switching between dialing speech. The circuit is able to operate down to D.C. line voltage of 1.6V (with reduced performance) to facilitate the use of more telephone sets in parallel.

### FEATURES

- \* Low d.c. line voltage; operates down to 1.6V (excluding polarity guard).
- \* Voltage regulator with adjustment static resistance.
- \* Provides supply with limited current for external circuitry.
- \* Symmetrical high-impedance inputs (64kΩ) for dynamic, magnetic or piezoelectric microphones.
- \* Asymmetrical high-impedance inputs (32kΩ) for electrets microphones.
- \* DTMF signal input with confidence tone.
- \* Mute input for pulse or DTMF dialing.
- \* Receiving amplifier for several types of earphones.
- \* Large amplification setting range on microphone and earpiece amplifiers.
- \* Line loss compensation facility, line current dependant (microphone and earpiece amplifiers).
- \* Gain control adaptable to exchange supply.
- \* Possibility to adjust the d.c. line voltage

### ■ ABSOLUTE MAXIMUM RATINGS

PARAMETER	SYMBOL	RATINGS	UNIT
Positive Continuous Line Voltage	$V_{LN}$	12	V
Repetitive Line Voltage During Switch-On Or Line Interruption	$V_{LN(RL)}$	13.2	V
Repetitive Peak Line Voltage for a 1 ms Pulse/5s(R10=13 $\Omega$ , R9=20 $\Omega$ (see Fig.15))	$V_{LN(RPL)}$	28	V
Line Current (Note1) (R9=20 $\Omega$ )	$I_{LINE}$	140	mA
Voltage on All Other Pins	$V_{I(+)}$	$V_{CC}+0.7$	V
	$V_{I(-)}$	-0.7	V
Total Power Dissipation (Note2) (R9=20 $\Omega$ )	$P_D$	640	mW
Junction Temperature	$T_J$	+125	$^{\circ}C$
Operating Ambient Temperature Range	$T_{OPR}$	-25 ~ +75	$^{\circ}C$
Storage Temperature Range	$T_{STG}$	-40 ~ +125	$^{\circ}C$

Note: 1. Mostly dependent on the maximum required  $T_a$  and the voltage between LN and SLPE (see Figs 6 ).

2. Calculated for the maximum ambient temperature specified  $T_a=75^{\circ}C$  and a maximum junction temperature of  $125^{\circ}C$ .

3. Absolute maximum ratings are those values beyond which the device could be permanently damaged. Absolute maximum ratings are stress ratings only and functional device operation is not implied.

## ■ FUNCTIONAL DESCRIPTION

### Supply: V<sub>CC</sub>, LN, SLPE, REG and STAB

Power for the UTC TEA1062N/TEA1062AN and its peripheral circuits is usually obtained from the telephone line. The IC supply voltage is derived from the line via a dropping resistor and regulated by the UTC TEA1062N/TEA1062AN. The supply voltage V<sub>CC</sub> may also be used to supply external circuits e.g. dialling and control circuits. Decoupling of the supply voltage is performed by a capacitor between V<sub>CC</sub> and V<sub>EE</sub> while the internal voltage regulator is decoupled by a capacitor between REG and V<sub>EE</sub>. The DC current drawn by the device will vary in accordance with varying values of the exchange voltage (V<sub>exch</sub>), the feeding bridge resistance (R<sub>exch</sub>) and the DC resistance of the telephone line (R<sub>LINE</sub>). The UTC TEA1062N/TEA1062AN has an internal current stabilizer operating at a level determined by a 3.6kΩ resistor connected between STAB and V<sub>EE</sub> (see Fig.8). When the line current(I<sub>LINE</sub>) is more than 0.5mA greater than the sum of the IC supply current (I<sub>CC</sub>) and the current drawn by the peripheral circuitry connected to V<sub>CC</sub>(I<sub>P</sub>) the excess current is shunted to V<sub>EE</sub> via LN. The regulated voltage on the line terminal(V<sub>LN</sub>) can be calculated as:

$$V_{LN}=V_{ref}+I_{SLPE}*R9 \text{ or;}$$

$$V_{LN}=V_{ref}+[(I_{LINE} - I_{CC} - 0.5*10^{-3}A) - I_P]*R9$$

where: V<sub>ref</sub> is an internally generated temperature compensated reference voltage of 3.7V and R9 is an external resistor connected between SLPE and V<sub>EE</sub>. In normal use the value of R9 would be 20Ω. Changing the value of R9 will also affect microphone gain, DTMF gain, gain control characteristics, side tone level, maximum output swing on LN and the DC characteristics (especially at the lower voltages). Under normal conditions, when I<sub>SLPE</sub> ≧ I<sub>CC</sub>+0.5mA + I<sub>P</sub>, the static behavior of the circuit is that of a 3.7V regulator diode with an internal resistance equal to that of R9. In the audio frequency range the dynamic impedance is largely determined by R1. Fig.3 shows the equivalent impedance of the circuit.

At line currents below 9mA the internal reference voltage is automatically adjusted to a lower value(typically 1.6V at 1mA) This means that more sets can be operated in parallel with DC line voltages (excluding the polarity guard) down to an absolute minimum voltage of 1.6V. With line currents below 9mA the circuit has limited sending and receiving levels. The internal reference voltage can be adjusted by means of an external resistor(R<sub>VA</sub>). This resistor when connected between LN and REG will decrease the internal reference voltage and when connected between REG and SLPE will increase the internal reference voltage. Current(I<sub>P</sub>) available from V<sub>CC</sub> for peripheral circuits depends on the external components used. Fig.9 shows this current for V<sub>CC</sub> > 2.2V. If MUTE of TEA1062N is LOW (TEA1062AN is HIGH) when the receiving amplifier is driven the available current is further reduced. Current availability can be increased by connecting the supply IC(1081) in parallel with R1, as shown in Fig.16, or, by increasing the DC line voltage by means of an external resistor(R<sub>VA</sub>) connected between REG and SLPE.

### MICROPHONE INPUTS(MIC+ AND MIC-) AND GAIN PINS (GAS1 AND GAS2)

The UTC TEA1062N/TEA1062AN has symmetrical inputs. Its input impedance is 64kΩ (2\*32kΩ) and its voltage gain is typically 52 dB (when R7=68kΩ. see Fig.13). Dynamic, magnetic, piezoelectric or electret (with built-in FET source followers) can be used. Microphone arrangements are illustrated in Fig.10. The gain of the microphone amplifier can be adjusted between 44dB and 52dB to suit the sensitivity of the transducer in use. The gain is proportional to the value of R7 which is connected between GAS1 and GAS2. Stability is ensured by the external capacitors, C6 connected between GAS1 and SLPE and C8 connected between GAS1 and V<sub>EE</sub>. The value of C6 is 100pF but this may be increased to obtain a first-order low-pass filter. The value of C8 is 10 times the value of C6. The cut-off frequency corresponds to the time constant R7\*C6.

### MUTE INPUT (MUTE/MUTE)

A LOW (UTC TEA1062N is HIGH) level at UTC TEA1062AN  $\overline{\text{MUTE}}$  enables DTMF input and inhibited the microphone inputs and the receiving amplifier inputs; a HIGH (UTC TEA1062N is LOW) level or an open circuit does the reverse. Switching the mute input will cause negligible clicks at the telephone outputs and on the line. In case the line current drops below 6mA (parallel operation of more sets) the circuit is always in speech condition independent of the DC level applied to the MUTE/ $\overline{\text{MUTE}}$  input.

### DUAL-TONE MULTI-FREQUENCY INPUT (DTMF)

When the DTMF input is enabled dialling tones may be sent onto the line. The voltage gain from DTMF to LN is typically 25.5dB(when R7=68kΩ) and varies with R7 in the same way as the microphone gain. The signalling tones can be heard in the earpiece at a low level (confidence tone).

## ■ FUNCTIONAL DESCRIPTION(Cont.)

### RECEIVING AMPLIFIER (IR,QR AND GAR)

The receiving amplifier has one input (IR) and a non-inverting output (QR). Earpiece arrangements are illustrated in Fig.11. The IR to QR gain is typically 31dB (when R4=100kΩ). It can be adjusted between 20 and 31dB to match the sensitivity of the transducer in use. The gain is set with the value of R4 which is connected between GAR and QR. The overall receive gain, between LN and QR, is calculated by subtracting the anti-sidetone network attenuation (32dB) from the amplifier gain. Two external capacitors, C4 and C7, ensure stability. C4 is normally 100pF and C7 is 10 times the value of C4. The value of C4 may be increased to obtain a first-order low-pass filter. The cut-off frequency will depend on the time constant R4\*C4. The output voltage of the receiving amplifier is specified for continuous-wave drive. The maximum output voltage will be higher under speech conditions where the peak to RMS ratio is higher.

### AUTOMATIC GAIN CONTROL INPUT (AGC)

Automatic line loss compensation is achieved by connecting a resistor(R6) between AGC and V<sub>EE</sub>. The automatic gain control varies the gain of the microphone amplifier and the receiving amplifier in accordance with the DC line current. The control range is 5.8dB which corresponds to a line length of 5km for a 0.5mm diameter twisted pair copper cable with a DC resistance of 176Ω/km and average attenuation of 1.2dB/km. Resistor R6 should be chosen in accordance with the exchange supply voltage and its feeding bridge resistance(see Fig.12 and Table 1). The ratio of start and stop currents of the AGC curve is independent of the value of R6. If no automatic line loss compensation is required the AGC may be left open-circuit. The amplifier, in this condition, will give their maximum specified gain.

### SIDE-TONE SUPPRESSION

The anti-sidetone network, R1//Z<sub>LINE</sub>, R2, R3, R8, R9 and Z<sub>BAL</sub>, (see Fig.4) suppresses the transmitted signal in the earpiece. Compensation is maximum when the following conditions are fulfilled:

$$(a) R9 \times R2 = R1 \times \left( R3 + \frac{R8 \times Z_{BAL}}{R8 + Z_{BAL}} \right)$$

$$(b) \left[ \frac{Z_{BAL}}{Z_{BAL} + R8} \right] = \left[ \frac{Z_{LINE}}{Z_{LINE} + R1} \right]$$

If fixed values are chosen for R1, R2, R3 and R9 then condition(a) will always be fulfilled when  $|R8/Z_{BAL}| \ll R3$ .

To obtain optimum side-tone suppression condition(b) has to be fulfilled which results in:

$$Z_{BAL} = (R8/R1) Z_{LINE} = k \times Z_{LINE} \text{ where } k \text{ is a scale factor;}$$

$$K = (R8/R1).$$

The scale factor (k), dependent on the value of R8, is chosen to meet following criteria:

- (a) Compatibility with a standard capacitor from the E6 or E12 range for Z<sub>BAL</sub>,
- (b)  $|Z_{BAL}/R8| \ll R3$  fulfilling condition (a) and thus ensuring correct anti-sidetone bridge operation,
- (c)  $|Z_{BAL} + R8| \gg R9$  to avoid influencing the trans-mitter gain.

In practice Z<sub>LINE</sub> varies considerably with the type and length. The value chosen for Z<sub>BAL</sub> should therefore be for an average line length thus giving optimum setting for short or long lines.

### EXAMPLE:

The balance impedance Z<sub>BAL</sub> at which the optimum suppression is present can be calculated by: Suppose Z<sub>LINE</sub> = 210Ω+(1265Ω//140nF) representing a 5km line of 0.5 mm diameter, copper, twisted pair cable matched to 600Ω(176Ω/km;38nF/km). When k=0.64 then R8=390Ω, Z<sub>BAL</sub>=130Ω+(820Ω//220nF).

Fig.3 Equivalent impedance circuit

The anti-sidetone network for the UTC TEA1062N/TEA1062AN family shown in Fig.4 attenuates the signal received from the line by 32 dB before it enters the receiving amplifier. The attenuation is almost constant over the whole audio frequency range. Fig.5 shows a conventional Wheatstone bridge anti-sidetone circuit that can be used as an alternative. Both bridge types can be used with either resistive or complex set impedances.

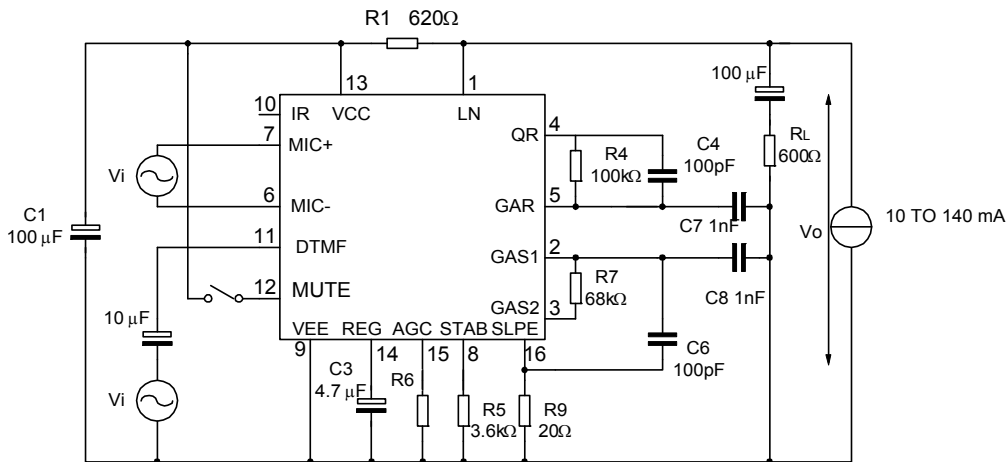

Fig.13 Test circuit defining voltage gain of MIC+, MIC- and DTMF inputs.

Voltage gain is defined as:  $G_v = 20 \cdot \log(|V_o/V_i|)$ . For measuring the gain from MIC+ and MIC- the MUTE input should be HIGH(UTC TEA1062N is LOW) or open-circuit, for measuring the DTMF input MUTE should be LOW(UTC TEA1062N is HIGH) .Inputs not under test should be open-circuit.

Fig.14 Test circuit for defining voltage gain of the receiving amplifier.  
Voltage gain is defined as:  $G_v = 20 \cdot \log(|V_o/V_i|)$ .

Fig.15 Typical application of the UTC TEA1062AN, shown here with a piezoelectric earpiece and DTMF dialling. The bridge to the left, the Zener diode and R10 limit the current into the circuit and the voltage across the circuit during line transients. Pulse dialling or register recall required a different protection arrangement. The DC line voltage can be set to a higher value by resistor  $R_{VA}$ (REG to SLPE).

Fig.16 Typical applications of the UTC TEA1062N/TEA1062AN (simplified)  
The dashed lines show an optional flash (register recall by timed loop break).
