The ISL59910 and ISL59913 are triple channel differential receivers and equalizers. They each contain three high speed differential receivers with five programmable poles. The outputs of these pole blocks are then summed into an output buffer. The equalization length is set with the voltage on a single pin. The ISL59910 and ISL59913 output can also be put into a high impedance state, enabling multiple devices to be connected in parallel and used in multiplexing application.

The gain can be adjusted up or down on each channel by 6 dB using its $\mathrm{V}_{\text {GAIN }}$ control signal. In addition, a further 6 dB of gain can be switched in to provide a matched drive into a cable.

The ISL59910 and ISL59913 have a bandwidth of 150 MHz and consume just 108 mA on $\pm 5 \mathrm{~V}$ supply. A single input voltage is used to set the compensation levels for the required length of cable.
The ISL59910 is a special version of the ISL59913 that decodes syncs encoded onto the common modes of three pairs of CAT-5 cable by the EL4543. (Refer to the EL4543 datasheet for details.)
The ISL59910 and ISL59913 are available in a 28 Ld QFN package and are specified for operation over the full $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ temperature range.

## Pinouts

## Features

- 150MHz -3dB bandwidth
- CAT-5 compensation
- 100MHz @ 600 ft
- 135MHz @ 300 ft
- 108mA supply current
- Differential input range 3.2 V
- Common mode input range -4 V to +3.5 V
- $\pm 5 \mathrm{~V}$ supply
- Output to within 1.5 V of supplies
- Available in 28 Ld QFN package
- Pb-free plus anneal available (RoHS compliant)

## Applications

- Twisted-pair receiving/equalizer
- KVM (Keyboard/Video/Mouse)
- VGA over twisted-pair
- Security video

## Ordering Information

## Applications Information

## Logic Control

The ISL59913 has two logical input pins, Chip Enable (ENABLE) and Switch Gain (X2). The logic circuits all have a nominal threshold of 1.1 V above the potential of the logic reference pin (VREF). In most applications it is expected that this chip will run from a $+5 \mathrm{~V}, 0 \mathrm{~V},-5 \mathrm{~V}$ supply system with logic being run between 0 V and +5 V . In this case the logic reference voltage should be tied to the 0 V supply. If the logic is referenced to the -5 V rail, then the logic reference should be connected to -5 V . The logic reference pin sources about $60 \mu \mathrm{~A}$ and this will rise to about $200 \mu \mathrm{~A}$ if all inputs are true (positive).

The logic inputs all source up to $10 \mu \mathrm{~A}$ when they are held at the logic reference level. When taken positive, the inputs sink a current dependent on the high level, up to $50 \mu \mathrm{~A}$ for a high level 5 V above the reference level.

The logic inputs, if not used, should be tied to the appropriate voltage in order to define their state.

## Control Reference and Signal Reference

Analog control voltages are required to set the equalizer and contrast levels. These signals are voltages in the range 0 V to 1 V , which are referenced to the control reference pin. It is expected that the control reference pin will be tied to 0 V and the control voltage will vary from 0 V to 1 V . It is; however, acceptable to connect the control reference to any potential between -5 V and 0 V to which the control voltages are referenced.

The control voltage pins themselves are high impedance. The control reference pin will source between $0 \mu \mathrm{~A}$ and $200 \mu \mathrm{~A}$ depending on the control voltages being applied.

The control reference and logic reference effectively remove the necessity for the 0 V rail and operation from $\pm 5 \mathrm{~V}$ (or 0 V and 10 V )

FIGURE 24. PACKAGE POWER DISSIPATION vs AMBIENT TEMPERATURE
only is possible. However we still need a further reference to define the 0 V level of the single ended output signal. The reference for the output signal is provided by the 0 V pin. The output stage cannot pull fully up or down to either supply so it is important that the reference is positioned to allow full output swing. The OV reference should be tied to a 'quiet ground' as any noise on this pin is transferred directly to the output. The 0 V pin is a high impedance pin and draws DC bias currents of a few $\mu \mathrm{A}$ and similar levels of $A C$ current.

## Equalizing

When transmitting a signal across a twisted pair cable, it is found that the high frequency (above 1 MHz ) information is attenuated more significantly than the information at low frequencies. The attenuation is predominantly due to resistive skin effect losses and has a loss curve which depends on the resistivity of the conductor, surface condition of the wire and the wire diameter. For the range of high performance twisted pair cables based on $24 a w g$ copper wire (CAT-5 etc). These parameters vary only a little between cable types and in general cables exhibit the same frequency dependence of loss. (The lower loss cables can be compared with somewhat longer lengths of their more lossy brothers.) This enables a single equalizing law equation to be built into the ISL59913.

With a control voltage applied between pins VCTRL and VREF, the frequency dependence of the equalization is shown in Figure 8. The equalization matches the cable loss up to about 100 MHz . Above this, system gain is rolled off rapidly to reduce noise bandwidth. The roll-off occurs more rapidly for higher control voltages, thus the system (cable + equalizer) bandwidth reduces as the cable length increases. This is desirable, as noise becomes an increasing issue as the equalization increases.

## Contrast

By varying the voltage between pins VGAIN and VREF, the gain of the signal path can be changed in the ratio 4:1. The gain change varies almost linearly with control voltage. For normal operation it is anticipated the X 2 mode will be selected and the output load will be back matched. A unity gain to the output load will then be achieved with a gain control voltage of about 0.35 V . This allows the gain to be trimmed up or down by 6 dB to compensate for any gain/loss errors that affect the contrast of the video signal. Figure 26 shows an example plot of the gain to the load with gain control voltage.

FIGURE 25. VARIATION OF GAIN WITH GAIN CONTROL VOLTAGE

## Common Mode Sync Decoding

The ISL59910 features common mode decoding to allow horizontal and vertical synchronization information, which has been encoded on the three differential inputs by the EL4543, to be decoded. The entire RGB video signal can therefore be transmitted, along with the associated synchronization information, by using just three twisted pairs.

Decoding is based on the EL4543 encoding scheme, as described in Figure 26 and Table 1. The scheme is a three-level system, which has been designed such that the sum of the common mode voltages results in a fixed average DC level with no AC content. This eliminates the effect of EMI radiation into the common mode signals along the twisted pairs of the cable

The common mode voltages are initially extracted by the ISL59910 from the three input pairs. These are then passed to an
internal logic decoding block to provide Horizontal and Vertical sync output signals ( $\mathrm{H}_{\text {OUT }}$ and $\mathrm{V}_{\text {OUT }}$ ).

## Power Dissipation

The ISL59910 and ISL59913 are designed to operate with $\pm 5 \mathrm{~V}$ supply voltages. The supply currents are tested in production and guaranteed to be less than 39 mA per channel. Operating at $\pm 5 \mathrm{~V}$ power supply, the total power dissipation is:
$\mathrm{PD}_{\text {MAX }}=3 \times\left\lceil 2 \times \mathrm{V}_{\mathrm{S}} \times \mathrm{I}_{\text {SMAX }}+\left(\mathrm{V}_{\mathrm{S}}-\mathrm{V}_{\text {OUTMAX }}\right) \times \frac{\mathrm{V}_{\text {OUTMAX }}}{\mathrm{R}_{\mathrm{L}}}\right\rceil$
(EQ. 1)
where:

- $\mathrm{PD}_{\text {MAX }}=$ Maximum power dissipation
- $\mathrm{V}_{\mathrm{S}}=$ Supply voltage $=5 \mathrm{~V}$
- $\mathrm{I}_{\mathrm{MAX}}=$ Maximum quiescent supply current per channel $=39 \mathrm{~mA}$
- $\mathrm{V}_{\text {OUTMAX }}=$ Maximum output voltage swing of the application $=2 \mathrm{~V}$
$R_{L}=$ Load resistance $=150 \Omega$
$P D_{M A X}=1.29 \mathrm{~W}$
(EQ. 2)
$\theta_{\mathrm{JA}}$ required for long term reliable operation can be calculated. This is done using Equation 3:

Where
$\theta_{J A}=\frac{(T j-T a)}{P D}=50.4 \mathrm{CW}$
Tj is the maximum junction temperature $\left(+150^{\circ} \mathrm{C}\right)$
Ta is the maximum ambient temperature $\left(+85^{\circ} \mathrm{C}\right)$
For a QFN 28 package in a properly layout PCB heatsinking copper area, $+37^{\circ} \mathrm{C} / \mathrm{W} \theta_{\mathrm{JA}}$ thermal resistance can be achieved. To disperse the heat, the bottom heatspreader must be soldered to the PCB. Heat flows through the heatspreader to the circuit board copper then spreads and converts to air. Thus the PCB copper plane becomes the heatsink. This has proven to be a very effective technique. A separate application note details the 28 Ld QFN. PCB design considerations are available.

Rev 10 12/04
NOTES:

1. Dimensioning and tolerancing per ASME Y14.5M-1994.
2. Tiebar view shown is a non-functional feature.
3. Bottom-side pin \#1 I.D. is a diepad chamfer as shown.
4. N is the total number of terminals on the device.
5. NE is the number of terminals on the " $E$ " side of the package (or Y-direction).
6. ND is the number of terminals on the " $D$ " side of the package (or X -direction). $\mathrm{ND}=(\mathrm{N} / 2)-\mathrm{NE}$.
7. Inward end of terminal may be square or circular in shape with radius (b/2) as shown.
8. If two values are listed, multiple exposed pad options are available. Refer to device-specific datasheet.
