

QL5064 QuickPCI Data Sheet

- **66 MHz/64-bit PCI Master/Target with Embedded Programmable Logic and dual Port SRAM**

1.0 Device Highlights

High Performance PCI Controller

- 64-bit / 66 MHz Master/Target PCI Controller (automatically backwards compatible to 33 MHz or/and 32-bits)
- 75 MHz PCI Interface supported for embedded systems
- PCI Specification v2.2 compliance
- Programmable back-end interface with three 64-bit busses/100 MHz
- Provides full 533 MB/s PCI data transfer rates (600 MB/s at 75 MHz)

Advanced PCI Features

- DMA Chaining mode for queued DMA transactions
- Four-channel DMA mastering, plus a SPCI (Single PCI Access) mode
- Unlimited bursts supported in Master and Target mode
- Two Master Write FIFOs and two Master Read FIFOs, each 64-deep and 64 bits wide
- Target Read and Write FIFOs for pre-fetched reads and multiposted writes
- Programmable interrupt controller
- I2O compliant under microprocessor control
- 16 Mailbox registers for message passing and semaphores
- Extended configuration space allowing Messaged Interrupts, power management, and future PCI enhancement support

Extremely Flexible and Configurable

- Supports processor-less systems, as well as 0 wait-state burst connections to all known 8/16/32/64 bit processors
- Includes non-volatile on-chip configuration data for total customization
- Independent PCI bus (66 MHz) and local bus (100 MHz) clocks
- All local interface, control, and glue-logic can be implemented on chip
- “PCI friendly” pinout simplifies board layout, supports 4-layer PCI boards

Advanced Master DMA Features

- Programmable DMA Channel Arbitration Scheme
- SPCI (Single PCI Access) mode may initiate any PCI Master command
- DMA controller configurable via PCI or back-end
- DMA Chaining mode allows a linked list of DMA transfers to occur without user intervention

High Performance PCI Target

- Write posting FIFO increases performance with queued transactions (up to 16 queued writes)
- Any BAR can be defined as pre-fetchable
- Six base address registers supported, configurable as memory or IO
- Unique “Target Blast Mode” enables high-performance and very low overhead streaming data to/from PCI

Expanded PCI Functionality

- Support for Configuration Space from 0x40 to 0x3FF
- PCI expanded capabilities support
- Expansion ROM supported with back-end memory
- Power management support
- Compact PCI hot-swap/hot-plug compliant
- Messaged Interrupts
- Configuration specified with anti-fuses on board, external EEPROM not needed

Programmable Logic

- 192 Programmable I/O pins in a 456 pin or 484 pin PBGA package
- 74K gates with 11 blocks (total of 12,672 bits) of dual-port RAM
- 250 MHz 16-bit counters, 275 MHz Datapaths, 160 MHz FIFOS
- All back-end interface and glue-logic can be implemented on chip

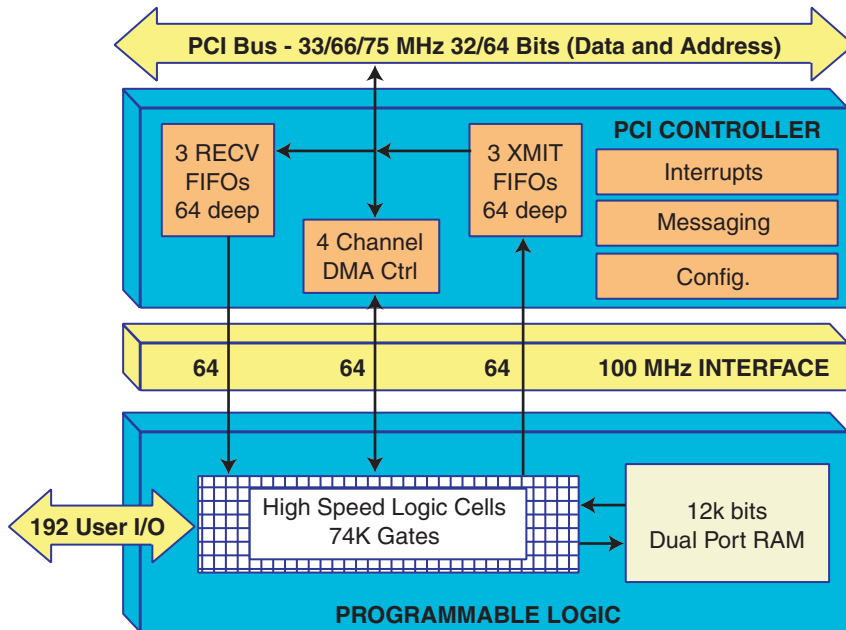

Figure 1: QL5064 Block Diagram

2.0 Architecture Overview

The QL5064 device in the QuickLogic QuickPCI ESP (Embedded Standard Products) family provides a complete and customizable PCI interface solution combined with 74,000 system gates of programmable logic. This device eliminates any need for the designer to worry about PCI bus compliance, yet allows for the maximum possible PCI bus bandwidth.

The programmable logic portion of the device is built from 792 QuickLogic Logic Cells, and 11 QuickLogic Dual-Port RAM Blocks. The configurable RAM blocks can each operate in 64x18, 128x9, 256x4, or 512x2 mode. These dual-port RAM blocks can be cascaded to achieve deeper or wider configurations. They can also be combined with logic cells to form FIFOs. See the RAM section of this data sheet for more information.

The QL5064 device includes a complete pre-designed PCI Initiator/Target interface offering full burst mode transfers at 32 or 64 bits per clock cycle. At 66 MHz, this device offers support for 533 Mbytes/sec data transfer rates ($66.6 \text{ MHz} * 8 \text{ bytes per transfer}$). At the maximum speed of 75 MHz (exceeding the current maximum speed specification for PCI), the QL5064 device can achieve 600 Mbytes/sec data transfer rates. The PCI interface is configured via internal programmable configuration bits, so no external EEPROM or memory is needed.

The QL5064 device meets PCI 2.2 electrical and timing specifications and has been fully hardware-tested. This device also supports the Win'98 and PC'98 standards. The QL5064 device features 3.3-volt operation with multi-volt compatible I/Os. Thus it can easily operate in 3.3-volt only systems, as well as mixed 3.3 volt/5 volt system. It can be placed on a universal signaling PCI board.

A wide range of additional features complements the QL5064 device. The FPGA side of the device is 5 volt and 3.3-volt PCI-compliant and is capable of implementing FIFOs at 160 MHz, and counters at over 250 MHz. I/O pins provide individually controlled output enables, dedicated input/feedback registers, and full JTAG capability for boundary scan and test. In addition, the QL5064 device provides the benefits of non-volatility, high design security, immediate functionality on power-up, and a self-contained single chip solution.

Figure 2: QL5064 Device Block Diagram

3.0 Applications

The QL5064 device supports maximum PCI transfer rates, so many applications exist which are ideally suited to the device's high performance. High speed data communications, telecommunications, and computing systems are just a few of the broad range of applications areas that can benefit from the high speed PCI interface and programmable logic.

The PCI Interface can also act as a PCI Host Controller. This can be accomplished by glue-less interface to most popular 8/16/32/64-bit microprocessors.

4.0 Six FIFOs for Increased Performance

The PCI interface includes the following 6 FIFO buffers:

- 2 64x64 PCI Master Transmit Buffers
- 2 64x64 PCI Master Receive Buffers
- 1 16x64 PCI Target Read/Pre-Fetch Buffer
- 1 32x64 PCI Target Write/Post Buffer

All FIFO buffers are 72 bits wide (64 data bits + 8-bit byte enables). PCI Initiator-mode buffers are 64 deep and support sustained burst transfers. PCI Target mode buffers are provided for both Read and Write operations to the PCI Target, supporting pre-fetched reads with configurable registers.

All FIFOs can operate with independent read and write clocks, so that the programmable logic design can interface to the FIFOs at up to 100 MHz (a clock asynchronous to the 33/66 MHz PCI clock). All data synchronization is accomplished in the PCI core.

The transmit FIFOs have full flags and the receive FIFOs have empty flags. Both types of FIFOs have programmable status flags that may be used to determine if either of the transmit FIFOs are almost full or if either of the receive FIFOs are almost empty.

5.0 DMA Feature Overview

Each Master-mode FIFO has its own DMA controller to support maximum data throughput. Combining one Initiator-Mode Transmit FIFO with one Initiator-Mode Receive FIFO also supports DMA Chaining. This unique and flexible DMA chaining mode permits a 'linked-list' of transfers to be completed by the DMA controller without software or processor intervention.

DMA Registers are accessible by the FPGA (back-end interface), as well as the PCI bus.

DMA Chaining descriptors are made of 4 64-bit Quad-Words, or 32 bytes of data per descriptor. Each descriptor defines a DMA transaction (memory start location, size, read/write) as well as 88 bits of user-defined information (such as a descriptor identifier, or back-end address).

DMA Chaining is a powerful DMA feature, allowing the QL5064 device to drive continuous pre-defined DMA transactions with no processor or software interaction.

Single PCI Access (SPCI) reads and writes are supported for single quad-word transfers that do not require FIFOs. SPCI supports IO reads and writes, configuration reads and writes, special cycles, interrupt acknowledge cycles, as well as standard memory read/write transactions.

Figure 3: DMA Chaining Descriptor

6.0 Mailbox Registers and I₂O

The PCI interface contains 16 bytes of mailbox registers to support message/semaphore passing between the programmable logic design and the PCI bus. These mailbox registers are memory mapped to a dedicated register bank within the first 256 bytes of BAR 0. 8 bytes are provided for the FPGA to PCI direction, and 8 bytes are also provided for the PCI to FPGA direction. Status flags and interrupts are available for each direction as well. Figure 4 below shows the mailbox structure within the QL5064 device. Hardware controlled queues allow full I₂O messaging support with a processor and local I₂O drivers.

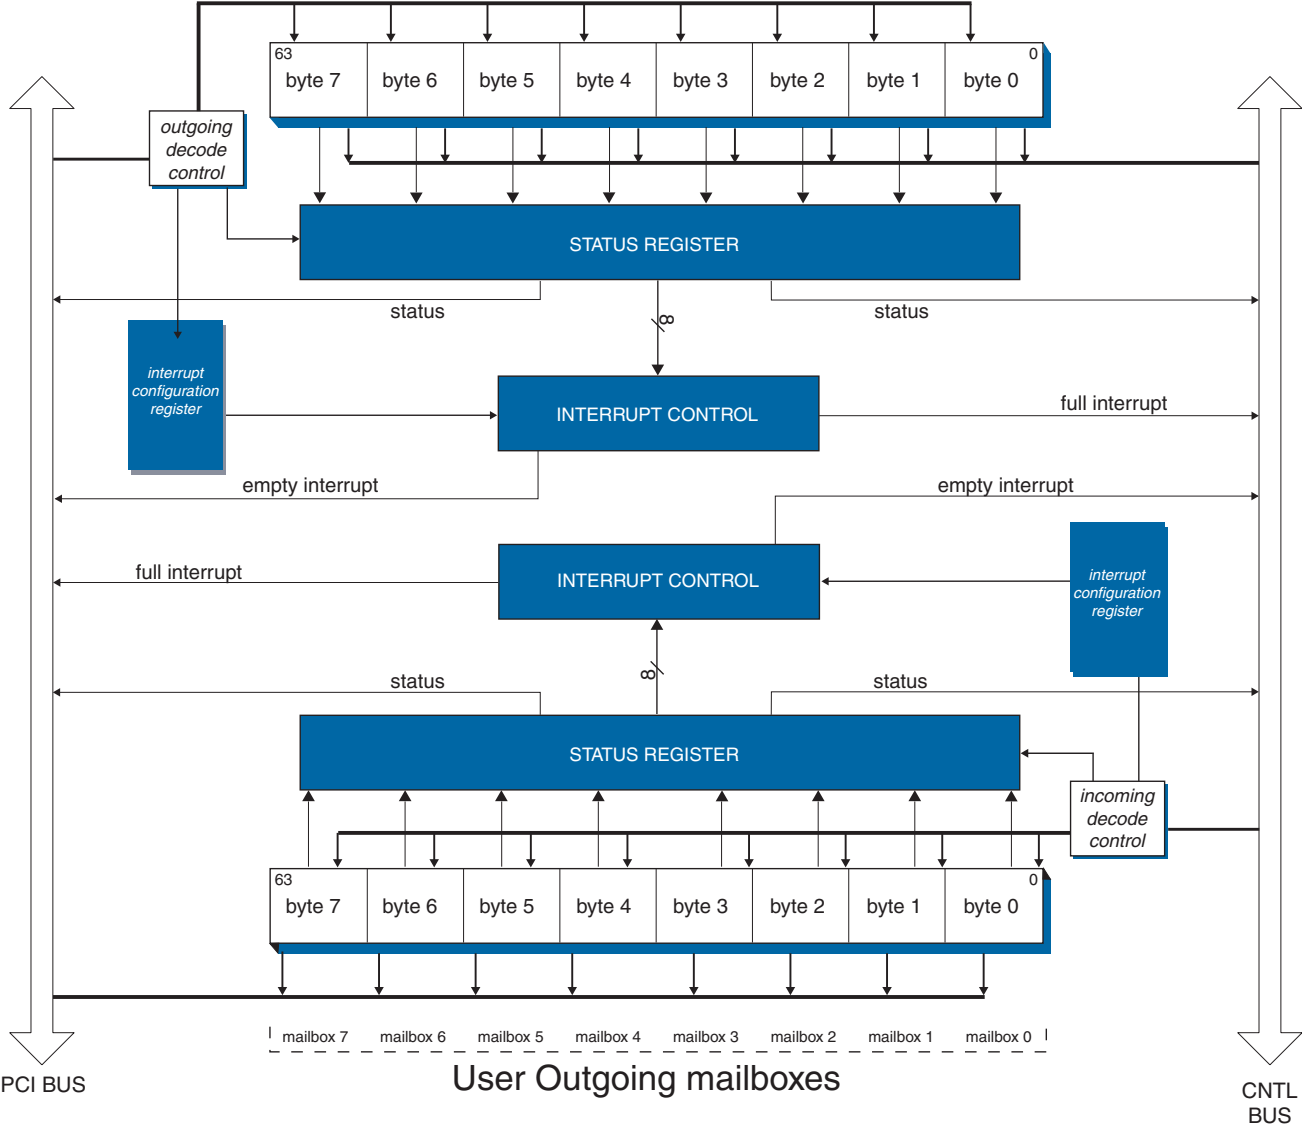

Figure 4: Mailbox Structure

7.0 QL5064 Internal Bus Structure

The internal interface between the PCI Controller and the FPGA logic cells is both simple and flexible. The interface is configurable, based on the needs of the FPGA design. Configuration is accomplished at the time of programming the FPGA.

The FPGA/PCI interface supports very high bandwidth data transfers via 3 64-bit busses. The interface is totally synchronous, and supports a separate clock from the PCI clock. The Interface clock can run at up to 100 MHz.

These busses are called DataIN, DataOUT, and Control_DATA. The DataIN bus is for moving data from the PCI bus to the back-end. The DataOUT bus is for moving data from the back-end to the PCI bus. The Control_DATA bus is for both of the above, and for accessing internal control registers. All 3 busses can operate at 0 wait states, and all can operate at the same time.

8.0 QL5064 Clocking

All bus accesses to the QL5064 from the FPGA (back-end) interface are synchronous to the back-end user clock - called user_clk. This clock is supplied on a dedicated external pin. The PCI clock may be routed out to a pin, and then back into the device to be used as the user_clk if desired. The user_clk signal may be asynchronous to the pci_clk signal, and may run at up to 100 MHz with no PLL requirements.

All busses on the back-end of the QL5064 device can sustain data movement on every cycle of user_clk.

Figure 5: FPGA to PCI Synchronization

9.0 DataIN Bus Description

The DataIN bus is used to transfer data from the PCI bus to the back-end interface. This data can come from three different data paths: one of the two DMA receive FIFOs, or the Target Write/Post FIFO. For proper data management, empty and almost empty flags from the two DMA receive FIFOs are available to the back-end design. The almost empty flags are fully configurable via the Control_DATA bus interface or the PCI bus. Interface to the Target Write/Post FIFO is accomplished through the Target interface signals. A block diagram of the DataIN and Target control connections is seen in Figure 6.

Data is transferred to the DataIN bus in the same byte lane in which it was transferred over the PCI bus. To assist with re-aligning or compacting data in the back-end interface, a byte-lane barrel shifter provides the means to manipulate byte lane positioning. This is accomplished with the byte_select[2:0] input. See the DataIN Bus section of the internal signal descriptions for more information.

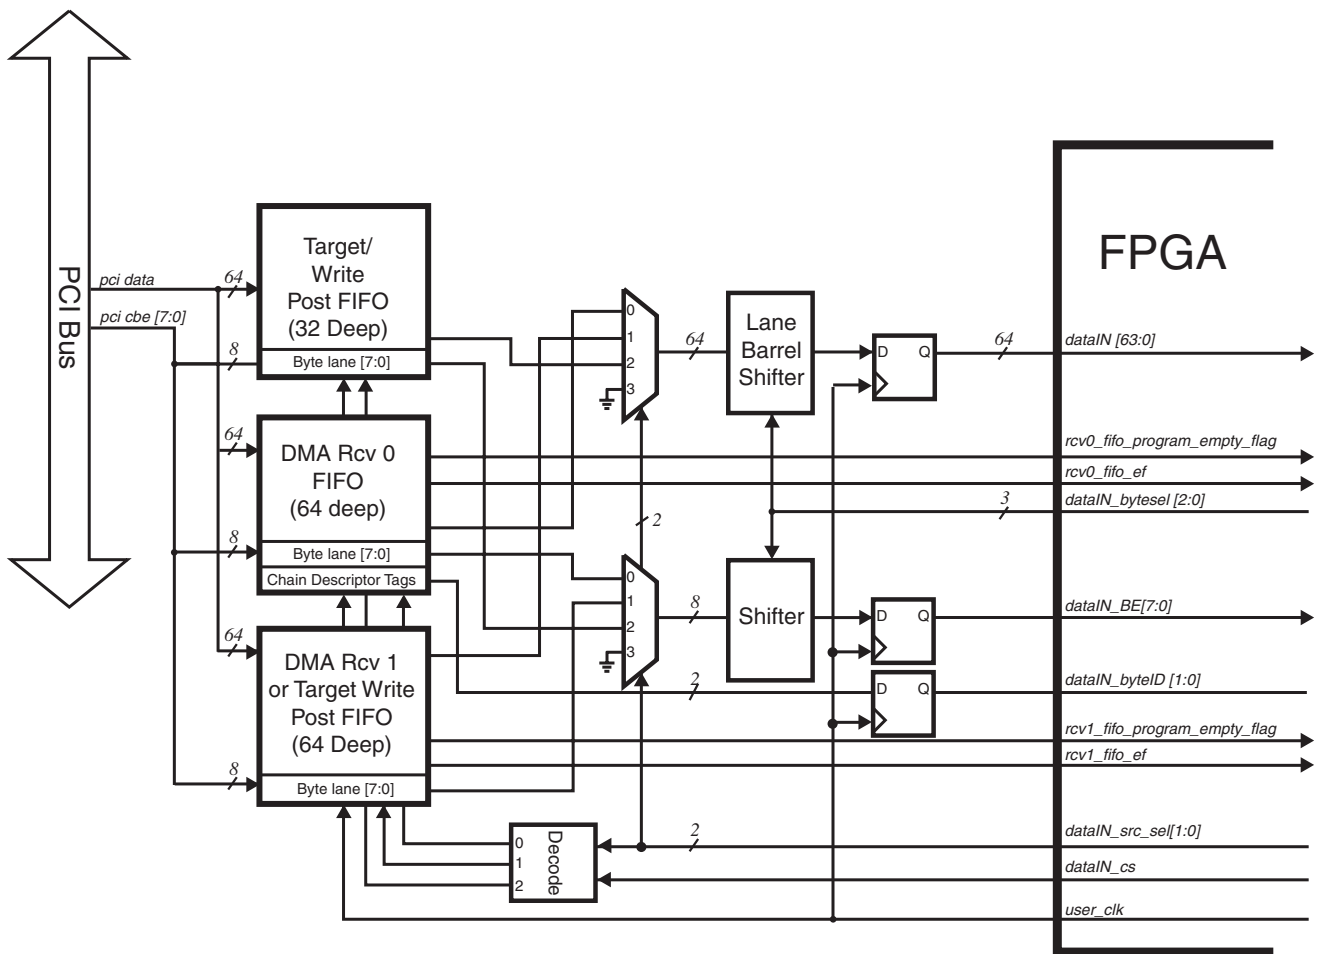

Figure 6: DataIN Bus Description

10.0 DataOUT Bus Description

The DataOUT bus is used to transfer data from the back-end interface to the PCI bus. This bus is connected to three destinations within the QL5064 device: one of the two DMA transmit FIFOs, or the Target Read/Pre-Fetch FIFO. For proper data management and high data throughput, full and almost full flags are available for each of the two DMA transmit FIFOs. The almost full flags are fully configurable via the Control_DATA bus interface or the PCI bus. Interface to the Target Read/Pre-Fetch FIFO is accomplished through the Target interface signals. A block diagram of the DataOUT connections can be seen in Figure 7.

The data_outDES[1:0] signals select a particular FIFO to be connected to the DataOUT bus. A block diagram of the DataOUT bus and its connections can be seen in Figure 7.

Data written to the DMA transmit FIFOs or the Target Read/Pre-fetch FIFO must be set up in the same byte lanes in which the data will be transferred in the PCI bus. To aid with aligning, re-aligning, or compacting data that is to be written to the FIFOs via the DataOUT bus, a byte-lane barrel shifter is present, controlled by the data_out_shift[2:0] signals. See the DataOUT bus section of the internal signal descriptions table for more information.

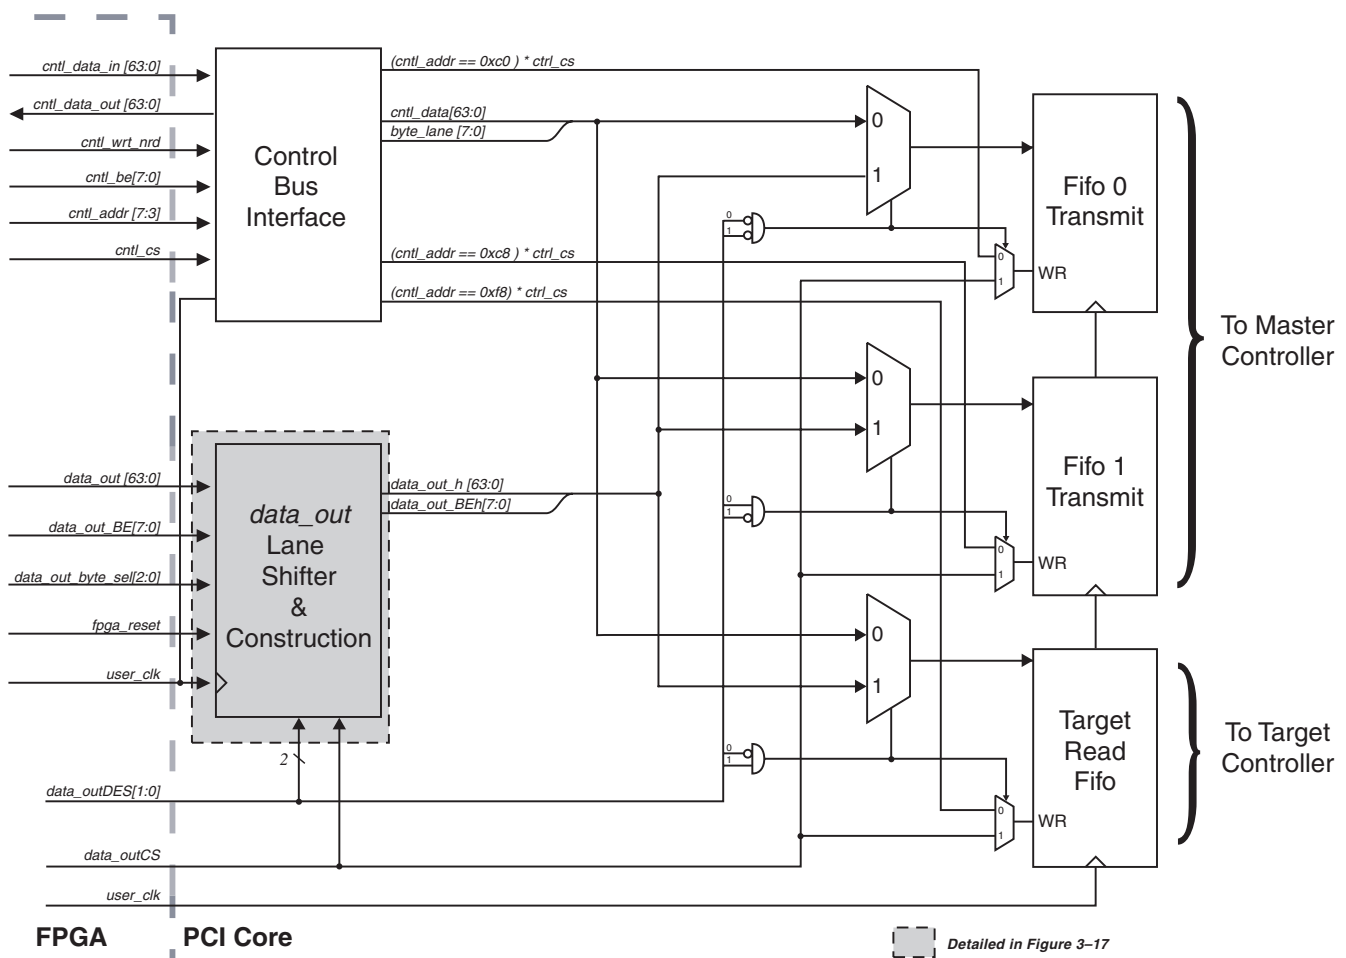

Figure 7: DataOUT and Control Bus Description

11.0 Control_Data Bus Descripton

The Control_DATA bus is the heart of the control circuitry for the PCI interface. The intent of this bus is to provide access to all of the control structures necessary for a microprocessor interfaced to the QL5064 device to be able to marshal all PCI operations. This bus, like the DataIN and DataOUT busses is synchronous to user_clk, and can be written or read on every clock. This is a bi-directional bus, offering both read and write access at 64-bits. In addition to all control structures, this bus is designed to access all of the six FIFOs.

12.0 PCI Master Arbitration

Five possible masters could be driving PCI master transactions on the PCI bus, and as a result, a flexible arbitration controller has been included in the QL5064 device. The five sources for PCI master transactions include: Transmit FIFO 0, Transmit FIFO 1, Receive FIFO 0, Receive FIFO 1, and SPCI (Single PCI Access). (SPCI is a means for the back end-design to initiate single quad-word transfers directly on the PCI bus for master transactions, bypassing the DMA FIFOs). SPCI Mastering is controlled through the Control_DATA bus.

Three arbitration modes have been defined for the QL5064 device. These are round robin, prioritized, and customized. In all modes, the SPCI Mastering always has highest priority. The arbitration scheme is selected by setting the proper values in the Arbitration Mode bits of configuration registers (offset 0xD0, bits 49:48). The selection is: 00b - round robin, 01b - prioritized, 10b - customized, 11b - reserved.

Round robin arbitration simply cycles through the four Master FIFOs in the following order: Transmit 0 (T0), Transmit 1 (T1), Receive 0 (R0), Receive 1 (R1). Prioritized mode uses values assigned to DMA_arbitration_priority bits in the configuration memory (offset 0xD0). Masters set to equal priority are arbitrated (high to low): T0, T1, R0, R1.

Customized arbitration mode uses two busses and back-end logic. The fpga_bus_req[3:0] signals (1 bit per FIFO) indicate to the programmable logic design which master is requesting the bus. The fpga_bus_req bits are assigned: [0]-R1, [1]-R0, [2]-T1, [3]-T0. The back-end design should set fpga_arb_sel[1:0] according to which master should be granted the bus. The fpga_arb_sel bus uses the enumeration: 00-R1, 01-R0, 10-T1, 11-T0.

13.0 Control Registers

DMA Control and QL5064 registers can be accessed from the PCI bus or the back-end Control_DATA bus. On the PCI side, these registers are accessed off of BAR 0, with offsets 0x00 to 0xFF (below 0x100). The breakdown of this memory space can be seen in the following table.

14.0 RAM Module Features

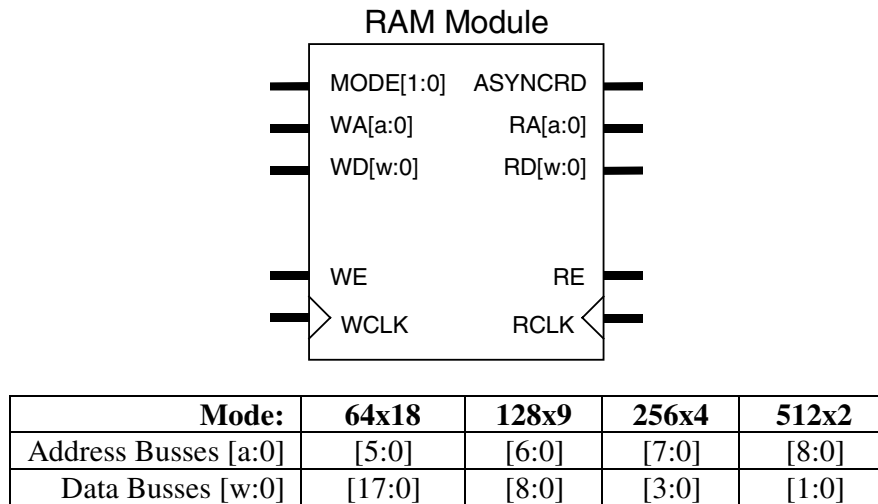

Figure 8: RAM Module

The RAM modules are "dual-ported", with completely independent READ and WRITE ports and separate READ and WRITE clocks. The READ ports support asynchronous and synchronous operation, while the WRITE ports support synchronous operation. Each port has 18 data lines and 9 address lines, allowing word lengths of up to 18 bits and address spaces of up to 512 words. Depending on the mode selected, however, some higher order data or address lines may not be used.

The Write Enable (WE) line acts as a clock enable for synchronous write operation. The Read Enable (RE) acts as a clock enable for synchronous READ operation (ASYNCRD input low), or as a flow-through enable for asynchronous READ operation (ASYNCRD input high).

Designers can cascade multiple RAM modules to increase the depth or width allowed in single modules by connecting corresponding address lines together and dividing the words between modules. This approach allows up to 512-deep configurations as large as 22 bits wide in the QL5064 device.

A similar technique can be used to create depths greater than 512 words. In this case address signals higher than the eighth bit are encoded onto the write enable (WE) input for WRITE operations. The READ data outputs are multiplexed together using encoded higher READ address bits for the multiplexer SELECT signals.

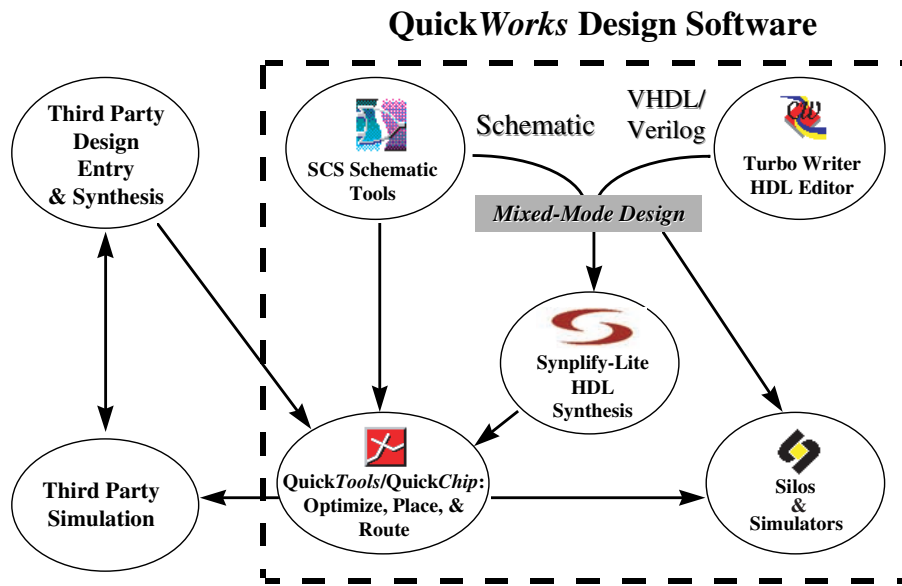

Figure 9: QuickWorks Tool Suite

15.0 JTAG Support

JTAG pins support IEEE standard 1149.1a to provide boundary scan capability for QL5064 devices. Six pins are dedicated to JTAG and programming functions on each QL5064 device, and are unavailable for general design input and output signals. TDI, TDO, TCK, TMS, and TRSTB are JTAG pins. A sixth pin, STM, is used only for programming.

16.0 Development Tool Support

Software support for the QL5064 device is available through the QuickWorks development package. This turnkey PC-based QuickWorks package, shown in Figure 9, provides a complete ESP software solution with design entry, logic synthesis, place and route, and simulation. QuickWorks includes VHDL, Verilog, schematic, and mixed-mode entry with fast and efficient logic synthesis provided by the integrated Synplicity Synplify Lite tool, specially tuned to take advantage of the QL5064 architecture. QuickWorks also provides functional and timing simulation for guaranteed timing and source-level debugging.

The UNIX-based QuickTools' and PC-based QuickWorks-Lite packages are a subset of QuickWorks and provide a solution for designers who use schematic-only design flow third-party tools for design entry, synthesis, or simulation. QuickTools and QuickWorks-Lite read EDIF netlists and provide support for all QuickLogic devices. QuickTools and QuickWorks-Lite also support a wide range of third-party modeling and simulation tools. In addition, the PC-based package combines all the features of QuickWorks-Lite with the SCS schematic capture environment, providing a low-cost design entry and compilation solution.

17.0 PCI to Programmable Logic Interface

The QL5064 device is designed to be highly customizable. This diagram illustrates the interface signals present between the configurable PCI core, and the programmable logic region of the QL5064 device. Detailed descriptions of each of these interface signals follow in the next section.

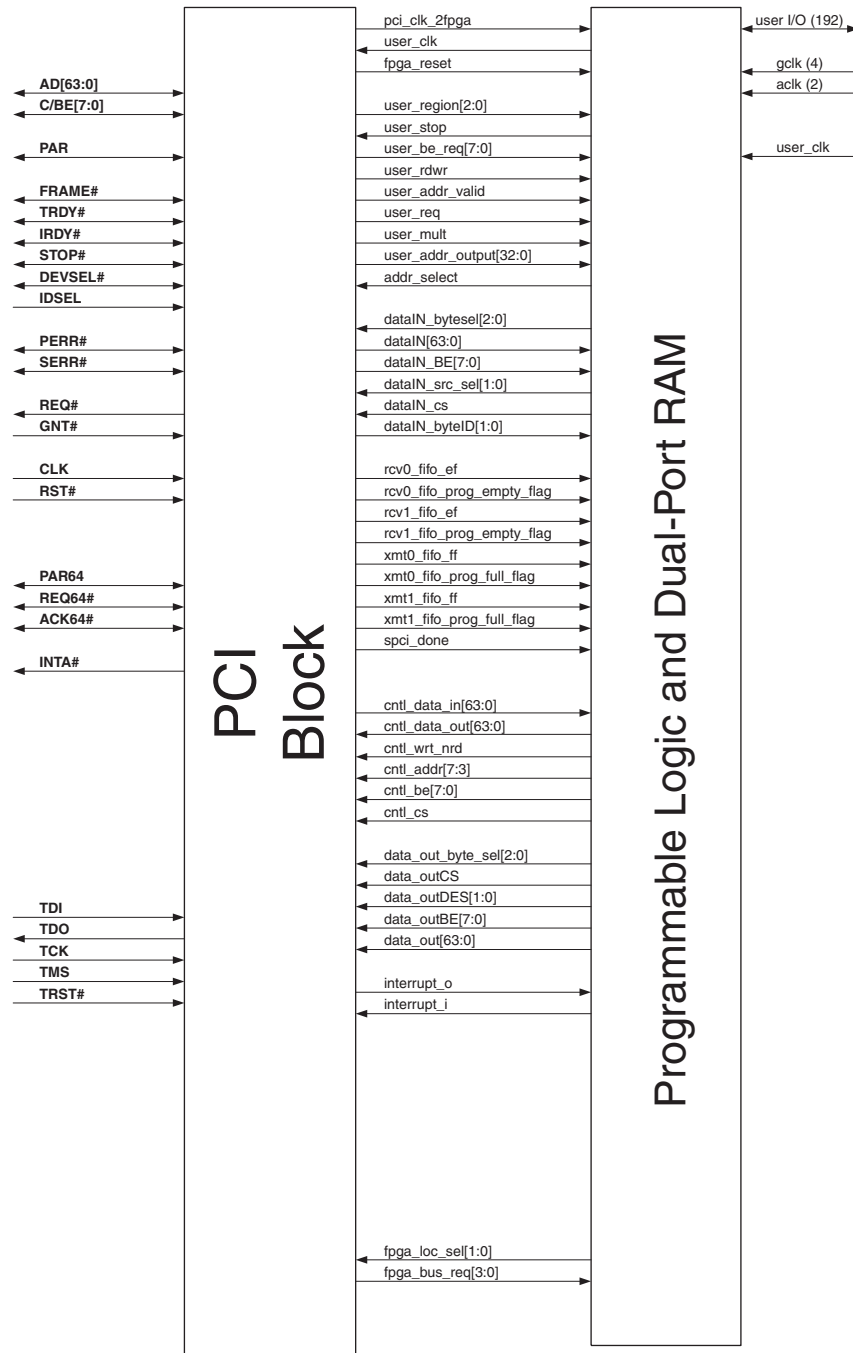

Figure 10: PCI to Programmable Logic Interface Block Diagram

18.0 PCI Back-End Interface Signals

These internal signals can interface directly to pins or to internal logic cells or RAM blocks in the programmable logic region of the device. These signals are used to customize the device so that it can connect to other devices on the board directly, with no glue-logic required.

Legend	
"O"	Output from FPGA to PCI
"I"	Input from PCI to FPGA

Table 1: PCI Back-End Interface Signals

Symbol	I/O	Description
Clocks		
pci_clk_2fpga	I	Buffered version of the PCI clock. For use in the FPGA.
user_clk	O	FPGA supplied clock used for all interface to the embedded PCI core. This signal is required and all communication between the embedded PCI core and the FPGA is synchronous to this clock with the exception of the DMA arbitrary signals.
fpga_reset	I	Global reset signal from the PCI core. Active High. This signal should be used as the global reset for the FPGA and all other supporting circuitry.
Target Interface		
user_region [2:0]	I	When <i>target_addr_valid</i> is active, these signals indicate which of the following regions are being accessed. 3'b000 BAR0 3'b001 BAR1 3'b010 BAR2 3'b011 BAR3 3'b100 BAR4 3'b101 BAR5 3'b110 Expansion ROM 3'b111 Configuration Space 0x40-0xff
user_stop	O	Active High. Stops prefetch after the current cycle.
user_be_req [7:0]	I	Active High. Byte lanes requested by PCI for all target accesses.
user_rdwr	I	When <i>target_addr_valid</i> is active, a logic '1' indicates that the requested transaction is a read. When '0' the present transaction is a write.
user_addr_valid	I	Active High. Indicates that PCI is requesting a sequentially continuing target access.
user_req	I	Active High. When active, PCI is requesting at least one piece of data to be transferred. Deasserted after an advance generated by a read or write from the target FIFO's or after 'target_user_stop' is asserted.
user_mult	I	Active High. PCI is requesting at least 2+ pieces of data to be transferred.
user_addr_output [32:0]	I	The current address of the PCI target transaction. Incremented automatically by a quad word when a 64-bit piece of target data is written or read.

(Sheet 1 of 4)

Table 1: PCI Back-End Interface Signals (Continued)

Symbol	I/O	Description																
addr_select	O	Selects which half of the 64-bit PCI address for a target transaction is placed on the user_addr [32:0] bus. 0 - [35:3] 1 - 00000. [63:36]																
DataIN Bus - (PCI - FPGA)																		
data_IN [63:0]	I	Active High. A 64-bit bus connecting to the FIFO's. Used by the FPGA to obtain data being transferred from the PCI bus to the FPGA.																
dataIN_src_sel[1:0]	O	Active High. Data source select signals determines which FIFO is connected to the <i>data_in</i> bus: 00 Receive FIFO0 01 Receive FIFO1 10 Target Write post FIFO 11 Not defined (returns 0)																
dataIN_cs	O	Active High. Chip select for read operations on the <i>data_in</i> bus. When active, advances the pointer for the FIFO selected by <i>dataIN_src_sel</i> [1:0]																
dataIN_BE[7:0]	I	Active High. Indicates which byte lane is active for the current transfer occurring on <i>dataIN</i> [63:0] <table border="0" style="width: 100%;"> <tr> <td style="width: 30%;"><i>dataIN_BE</i>[7]</td> <td><i>dataIN</i>[63:56]</td> </tr> <tr> <td><i>dataIN_BE</i>[6]</td> <td><i>dataIN</i>[55:48]</td> </tr> <tr> <td><i>dataIN_BE</i>[5]</td> <td><i>dataIN</i>[47:40]</td> </tr> <tr> <td><i>dataIN_BE</i>[4]</td> <td><i>dataIN</i>[39:32]</td> </tr> <tr> <td><i>dataIN_BE</i>[3]</td> <td><i>dataIN</i>[31:24]</td> </tr> <tr> <td><i>dataIN_BE</i>[2]</td> <td><i>dataIN</i>[23:16]</td> </tr> <tr> <td><i>dataIN_BE</i>[1]</td> <td><i>dataIN</i>[15:08]</td> </tr> <tr> <td><i>dataIN_BE</i>[0]</td> <td><i>dataIN</i>[07:00]</td> </tr> </table>	<i>dataIN_BE</i> [7]	<i>dataIN</i> [63:56]	<i>dataIN_BE</i> [6]	<i>dataIN</i> [55:48]	<i>dataIN_BE</i> [5]	<i>dataIN</i> [47:40]	<i>dataIN_BE</i> [4]	<i>dataIN</i> [39:32]	<i>dataIN_BE</i> [3]	<i>dataIN</i> [31:24]	<i>dataIN_BE</i> [2]	<i>dataIN</i> [23:16]	<i>dataIN_BE</i> [1]	<i>dataIN</i> [15:08]	<i>dataIN_BE</i> [0]	<i>dataIN</i> [07:00]

<i>dataIN_BE</i> [1]	<i>dataIN</i> [15:08]																	
<i>dataIN_BE</i> [0]	<i>dataIN</i> [07:00]																	
dataIN_bytesel[2:0]		<i>dataIN_BE</i> [7:0] are shifted along with the data. It is a number of bytes to barrel shift the 64-bit <i>dataIN</i> bus and the <i>dataIN_BE</i> bus.																
dataIN_bytelD[1:0]	I	Active High. Tag bits for the DMA chain descriptor pointer. When active, indicates that chain descriptor information is available at the output of Receive FIFO0. <table border="0" style="width: 100%;"> <tr> <td style="width: 30%;"><i>dataIN_bytelD</i>[1:0]</td> <td></td> </tr> <tr> <td>00</td> <td>normal data</td> </tr> <tr> <td>01</td> <td>Descriptor dword 0 (PCI starting address)</td> </tr> <tr> <td>10</td> <td>Descriptor dword 1 (user defined)</td> </tr> <tr> <td>11</td> <td>Descriptor dword 2 (transfer count, et al.)</td> </tr> </table>	<i>dataIN_bytelD</i> [1:0]		00	normal data	01	Descriptor dword 0 (PCI starting address)	10	Descriptor dword 1 (user defined)	11	Descriptor dword 2 (transfer count, et al.)						
<i>dataIN_bytelD</i> [1:0]																		
00	normal data																	
01	Descriptor dword 0 (PCI starting address)																	
10	Descriptor dword 1 (user defined)																	
11	Descriptor dword 2 (transfer count, et al.)																	
FIFO Status Signals																		
rcv0_fifo_ef	I	Active High. Receive FIFO0 is empty																
rcv0_fifo_prog_empty_flag	I	Active High. Receive FIFO0 contains a number of entries less than or equal to the threshold set in register 0x68, bits 37:32																
rcv1_fifo_ef	I	Active High. Receive FIFO1 is empty.																
rcv1_fifo_prog_empty_flag	I	Active High. Receive FIFO 1 contains a number of entries less than or equal to the threshold set in register 0x68, bits 45:40.																
xmt0_fifo_ff	I	Active High. Transmit FIFO0 is full.																
xmt0_fifo_prog_full_flag	I	Active High. Transmit FIFO0 contains a number of entries greater than or equal to the threshold set in register 0x68, bits 53:48.																
(Sheet 2 of 4)																		

Table 1: PCI Back-End Interface Signals (Continued)

Symbol	I/O	Description																
xmt1_fifo_ff	I	Active High. Transmit FIFO1 is full.																
xmt1_fifo_prog_full_flag	I	Active High. Transmit FIFO1 contains a number of entries greater than or equal to the threshold set in register 0x68, bits 61:56.																
Misc Interface Signals																		
SPCI_done	I	Active High. Single PCI Access done.																
Control Bus Interface Signals																		
cntl_data_in[63:0]	I	Active High. a 64-bit bus used to read to the various memory mapped registers of the QL5064.																
cntl_wrt_nrd	O	Control bus write/not read. When '1' current access to the control bus is a write. When '0' current access to the control bus is a read.																
cntl_addr[7:3]	O	Active High. Control bus address bits 7:3. Selects which of the 64-bit registers the control bus is accessing.																
cntl_be[7:0]	O	<table border="0"> <tr><td>cntl_be[7]</td><td>cntl_data[63:56]</td></tr> <tr><td>cntl_be[6]</td><td>cntl_data[55:48]</td></tr> <tr><td>cntl_be[5]</td><td>cntl_data[47:40]</td></tr> <tr><td>cntl_be[4]</td><td>cntl_data[39:32]</td></tr> <tr><td>cntl_be[3]</td><td>cntl_data[31:24]</td></tr> <tr><td>cntl_be[2]</td><td>cntl_data[23:16]</td></tr> <tr><td>cntl_be[1]</td><td>cntl_data[15:08]</td></tr> <tr><td>cntl_be[0]</td><td>cntl_data[07:00]</td></tr> </table>	cntl_be[7]	cntl_data[63:56]	cntl_be[6]	cntl_data[55:48]	cntl_be[5]	cntl_data[47:40]	cntl_be[4]	cntl_data[39:32]	cntl_be[3]	cntl_data[31:24]	cntl_be[2]	cntl_data[23:16]	cntl_be[1]	cntl_data[15:08]	cntl_be[0]	cntl_data[07:00]
cntl_be[7]	cntl_data[63:56]																	
cntl_be[6]	cntl_data[55:48]																	
cntl_be[5]	cntl_data[47:40]																	
cntl_be[4]	cntl_data[39:32]																	
cntl_be[3]	cntl_data[31:24]																	
cntl_be[2]	cntl_data[23:16]																	
cntl_be[1]	cntl_data[15:08]																	
cntl_be[0]	cntl_data[07:00]																	
cntl_data_out[63:0]	O	Active High. A 64-bit bus used to write to the various memory mapped registers of the QL5064.																
cntl_cs	O	Active High. Control bus chip select.																
Data OUT Bus Interface Signals																		
data_out[63:0]	O	A 64-bit bus connecting to the FIFO's. Used by the FPGA to write data from the FPGA to the PCI bus via the three output FIFO's.																
data_outCS	O	Active High. Chip select for the data_out bus.																
data_outDES[1:0]	O	Destination select for the data_out bus. <table border="0"> <tr><td>00</td><td>Transmit FIFO0</td></tr> <tr><td>01</td><td>Transmit FIFO1</td></tr> <tr><td>10</td><td>Target/Read Post FIFO</td></tr> <tr><td>11</td><td>No destination (parked)</td></tr> </table>	00	Transmit FIFO0	01	Transmit FIFO1	10	Target/Read Post FIFO	11	No destination (parked)								
00	Transmit FIFO0																	
01	Transmit FIFO1																	
10	Target/Read Post FIFO																	
11	No destination (parked)																	
data_out_byte_sel[2:0]	O	Lane shifting selection for the construction registers before the FIFO's data_out_BE[7:0] are also shifted accordingly. It is a number of bytes to barrel shift the 64-bit data_out bus and the 8-bit data_out BE bus.																
data_outBE[7:0]	O	<p>Active High. Indicates which byte lane is active for the current transfer occurring on data_out[63:0].</p> <table border="0"> <tr><td>data_outBE[7]</td><td>data_out[63:56]</td></tr> <tr><td>data_outBE[6]</td><td>data_out[55:48]</td></tr> <tr><td>data_outBE[5]</td><td>data_out[47:40]</td></tr> <tr><td>data_outBE[4]</td><td>data_out[39:32]</td></tr> <tr><td>data_outBE[3]</td><td>data_out[31:24]</td></tr> <tr><td>data_outBE[2]</td><td>data_out[23:16]</td></tr> <tr><td>data_outBE[1]</td><td>data_out[15:08]</td></tr> <tr><td>data_outBE[0]</td><td>data_out[07:00]</td></tr> </table>	data_outBE[7]	data_out[63:56]	data_outBE[6]	data_out[55:48]	data_outBE[5]	data_out[47:40]	data_outBE[4]	data_out[39:32]	data_outBE[3]	data_out[31:24]	data_outBE[2]	data_out[23:16]	data_outBE[1]	data_out[15:08]	data_outBE[0]	data_out[07:00]
data_outBE[7]	data_out[63:56]																	
data_outBE[6]	data_out[55:48]																	
data_outBE[5]	data_out[47:40]																	
data_outBE[4]	data_out[39:32]																	
data_outBE[3]	data_out[31:24]																	
data_outBE[2]	data_out[23:16]																	
data_outBE[1]	data_out[15:08]																	
data_outBE[0]	data_out[07:00]																	

(Sheet 3 of 4)

Table 1: PCI Back-End Interface Signals (Continued)

Symbol	I/O	Description
Interrupt Control		
interrupt_i	O	Active High and level sensitive. When active and not masked, asserts a PCI interrupt.
interrupt_o	I	Active High. Indicates an interrupt is pending for the FPGA to service.
Master Arbitration Control		
fpga_loc_sel[1:0]	O	FPGA arbitration select. If the FPGA has control of the master-modeling arbitration, these bits determine which DMA channel should initiate a DMA transfer after the next arbitration cycle. Has relationship to pci_clk. 00 => Receive channel 1 has access to the bus 01 => Receive channel 0 has access to the bus 10 => Transmit channel 1 has access to the bus 11 => Transmit channel 0 has access to the bus
fpga_bus_req[3:0]	I	Active High. Master request status. Indicates that the respective master has need to access the PCI bus. Has relationship to pci_clk. fpga_bus_req[0] = receive channel 1 fpga_bus_req[1] = receive channel 0 fpga_bus_req[2] = transmit channel 1 fpga_bus_req[3] = transmit channel 0

(Sheet 4 of 4)

19.0 Configuration Space

Defaults for most configuration space parameters can be programmed into the Via-Link antifuse based configuration region in the device. Also, by fully supporting the extended configuration space region beyond the 40(hex), the full enhanced feature set of the PCI bus is available to the user.

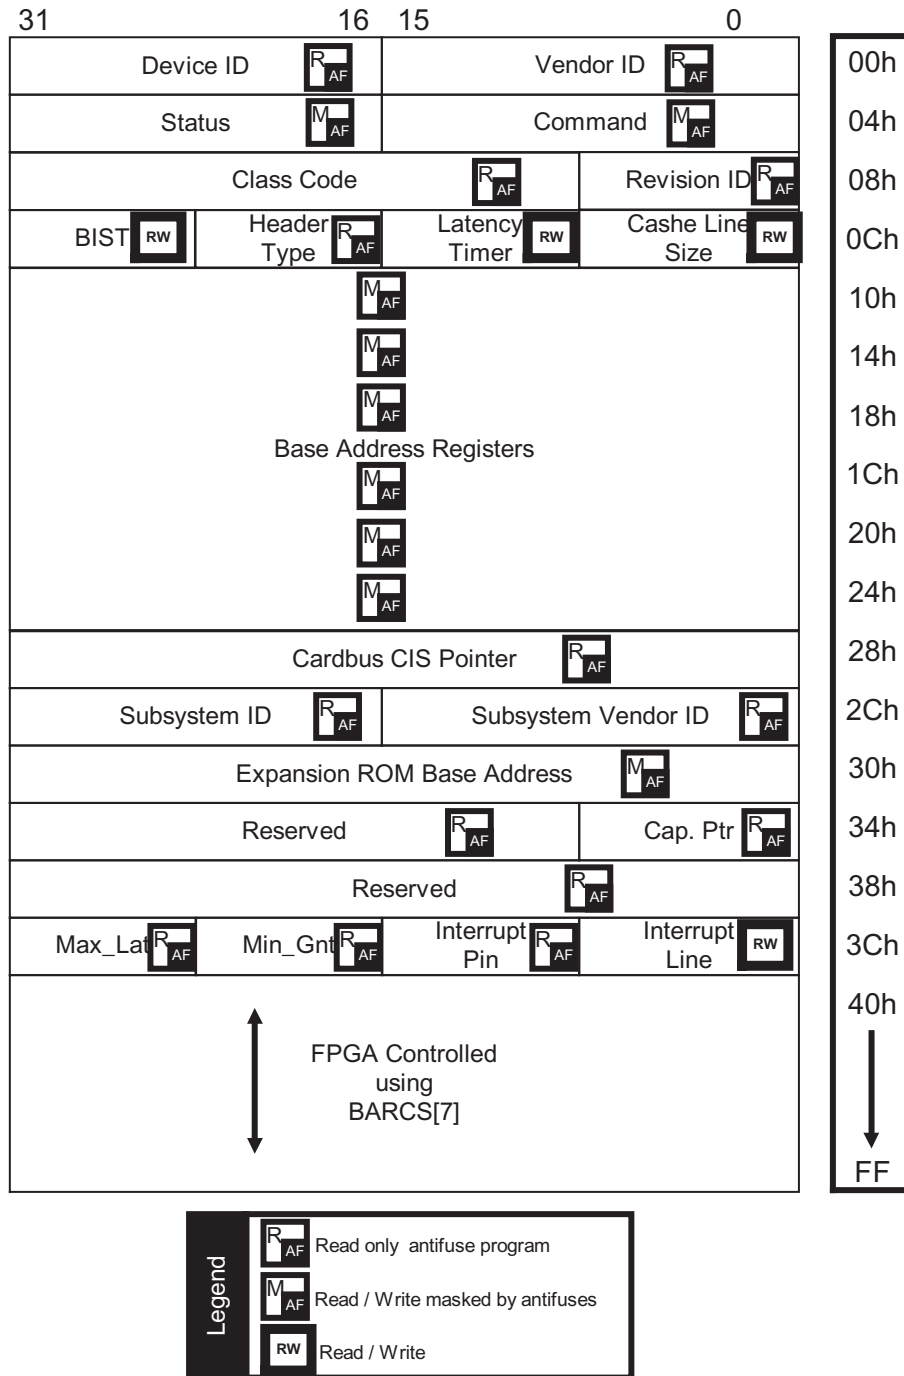

Figure 11: Configuration Space Block Diagram

20.0 AC Characteristics at Vcc = 3.3V, TA=25° C (K=1.00)

The AC Specifications, Logic Cell diagrams and waveforms are provided below. To calculate delays, multiply the appropriate K factor in the “Operating Range” section by the following numbers.

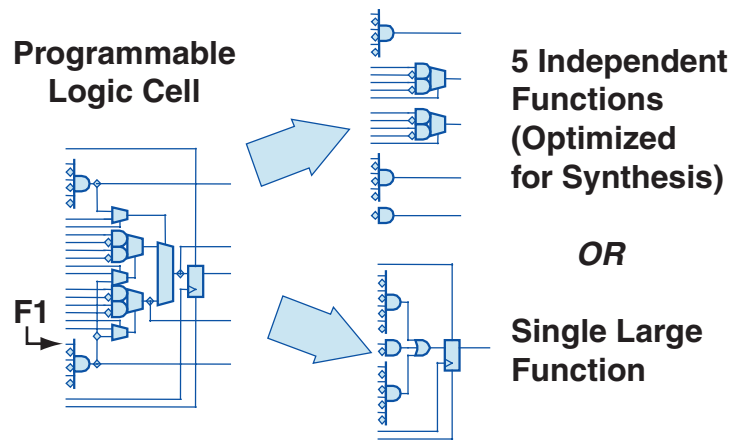

Figure 12: QuickPCI Logic Cell Configuration

Table 2: Logic Cells

Symbol	Parameter	Propagation Delays (ns)Fanout a				
		1	2	3	4	8
tPD	Combinatorial Delay b	1.4	1.7	2.0	2.3	3.5
tSU	Setup Time b	1.8	1.8	1.8	1.8	1.8
tH	Hold Time	0.0	0.0	0.0	0.0	0.0
tCLK	Clock to Q Delay	0.8	1.1	1.4	1.7	2.9
tCWHI	Clock High Time	1.6	1.6	1.6	1.6	1.6
tCWLO	Clock Low Time	1.6	1.6	1.6	1.6	1.6
tSET	Set Delay	1.4	1.7	2.0	2.3	3.5
tRESET	Reset Delay	1.2	1.5	1.8	2.1	3.3
tSW	Set Width	1.9	1.9	1.9	1.9	1.9
tRW	Reset Width	1.8	1.8	1.8	1.8	1.8

- a. Stated timing for worst case Propagation Delay over process variation at VCC=3.3V and TA=25°C. Multiply by the appropriate Delay Factor, K, for speed grade, voltage and temperature settings as specified in the Operating Range.
- b. These limits are derived from a representative selection of the slowest paths through the QuickRAM logic cell including typical net delays. Worst case delay values for specific paths should be determined from timing analysis of your particular design.

Table 3: RAM Cell Synchronous Write Timing

Symbol	Parameter	Propagation Delays (ns)Fanout				
		1	2	3	4	8
TSWA	WA Setup Time to WCLK	1.0	1.0	1.0	1.0	1.0
THWA	WA Hold Time to WCLK	0.0	0.0	0.0	0.0	0.0
TSWD	WD Setup Time to WCLK	1.0	1.0	1.0	1.0	1.0
THWD	WD Hold Time to WCLK	0.0	0.0	0.0	0.0	0.0
TSWE	WE Setup Time to WCLK	1.0	1.0	1.0	1.0	1.0
THWE	WE Hold Time to WCLK	0.0	0.0	0.0	0.0	0.0
TWCRD	WCLK to RD (WA=RA) [a]	5.0	5.3	5.6	5.9	7.1

Table 4: RAM Cell Synchronous Read Timing

Symbol	Parameter	Propagation Delays (ns)Fanout ^a				
		1	2	3	4	8
TSRA	RA Setup Time to RCLK	1.0	1.0	1.0	1.0	1.0
THRA	RA Hold Time to RCLK	0.0	0.0	0.0	0.0	0.0
TSRE	RE Setup Time to RCLK	1.0	1.0	1.0	1.0	1.0
THRE	RE Hold Time to RCLK	0.0	0.0	0.0	0.0	0.0
TRCRD	RCLK to RD [b]	4.0	4.3	4.6	4.9	6.1

Table 5: RAM Cell Asynchronous Read Timing

Symbol	Parameter	Propagation Delays (ns)Fanout				
		1	2	3	4	8
RPDRD	RA to RD [b]	3.0	3.3	3.6	3.9	5.1

Table 6: Input-Only Cells

Symbol	Parameter	Propagation Delays (ns)Fanout ^b							
		1	2	3	4	8	12	24	
TIN	High Drive Input Delay	1.5	1.6	1.8	1.9	2.4	2.9	4.4	
TINI	High Drive Input, Inverting Delay	1.6	1.7	1.9	2.0	2.5	3.0	4.5	
TISU	Input Register Set-Up Time	3.1	3.1	3.1	3.1	3.1	3.1	3.1	
TIH	Input Register Hold Time	0.0	0.0	0.0	0.0	0.0	0.0	0.0	
TICLK	Input Register Clock To Q	0.7	0.8	1.0	1.1	1.6	2.1	3.6	
TIRST	Input Register Reset Delay	0.6	0.7	0.9	1.0	1.5	2.0	3.5	
TIESU	Input Register Clock Enable Setup Time	2.3	2.3	2.3	2.3	2.3	2.3	2.3	
TIEH	Input Register Clock Enable Hold Time	0.0	0.0	0.0	0.0	0.0	0.0	0.0	

Table 7: Clock Cells

Symbols	Parameter	Propagation Delays (ns) Loads per Half Column [a]										
		1	2	3	4	8	10	12	14	16	18	20
tACK	Array Clock Delay	1.2	1.2	1.3	1.3	1.5	1.6	1.7	1.8	1.9	2	2.1
tGCKP	Global Clock Pin Delay	0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7	0.7
tGCKB	Global Clock Buffer Delay	0.8	0.8	0.9	0.9	1.1	1.2	1.3	1.4	1.5	1.6	1.7

- a. The array distributed networks consist of 40 half columns and the global distributed networks consist of 44 half columns, each driven by an independent buffer. The number of half columns used does not affect clock buffer delay. The array clock has up to 8 loads per half column. The global clock has up to 11 loads per half column.

Table 8: I/O Cell Input Delays

Symbol	Parameter	Propagation Delays (ns)Fanout [4]					
		1	2	3	4	8	10
tI/O	Input Delay (bidirectional pad)	1.3	1.6	1.8	2.1	3.1	3.6
TISU	Input Register Set-Up Time	3.1	3.1	3.1	3.1	3.1	3.1
TIH	Input Register Hold Time	0.0	0.0	0.0	0.0	0.0	0.0
TIOCLK	Input Register Clock To Q	0.7	1.0	1.2	1.5	2.5	3.0
TIORST	Input Register Reset Delay	0.6	0.9	1.1	1.4	2.4	2.9
TIESU	Input Register clock Enable Set-Up Time	2.3	2.3	2.3	2.3	2.3	2.3
TIEH	Input Register Clock Enable Hold Time	0.0	0.0	0.0	0.0	0.0	0.0

Table 9: I/O Cell Output Delays

Symbol	Parameter	Propagation Delays (ns) Output Load Capacitance (pF)				
		30	50	75	100	150
TOUTLH	Output Delay Low to High	2.1	2.5	3.1	3.6	4.7
TOUTHHL	Output Delay High to Low	2.2	2.6	3.2	3.7	4.8
TPZH	Output Delay Tri-state to High	1.2	1.7	2.2	2.8	3.9
TPZL	Output Delay Tri-state to Low	1.6	2.0	2.6	3.1	4.2
TPHZ	Output Delay High to Tri-State [a]	2.0				
TPLZ	Output Delay Low to Tri-State [a]	1.2				

a. The following loads are used for tPXZ:

Table 10: PCI DC Specifications for 3.3V Signaling

Symbol	Parameter	Condition	Min	Max	Units
Vcc	Supply Voltage		3.0	3.6	V
Vcc	Supply Voltage (for 75MHz only)		3.15	3.6	V

21.0 DC Characteristics

The DC Specifications are provided in the tables below.

Table 13: Absolute Maximum Ratings

V_{CC} Voltage	-0.5 to 4.6V	DC Input Current	±20 mA
V_{CCIO} Voltage	-0.5 to 7.0V	ESD Pad Protection	±2000V
Input Voltage	-0.5V to V _{CCIO} +0.5V	Storage Temperature	-65°C to +150°C
Latch-up Immunity	±200 mA	Max Lead Temperature	300°C

Table 14: Operating Range

Symbol	Parameter		Industrial		Commercial		Unit
			Min	Max	Min	Max	
VCC	Supply Voltage		3.0	3.6	3.0	3.6	V
VCCIO	I/O Input Tolerance Voltage		3.0	5.5	3.0	5.25	V
TA	Ambient Temperature		-40	85	0	70	°C
K	Delay Factor	-33A Speed Grade	0.42	1.29	0.46	1.25	
		-33B Speed Grade	0.42	1.14	0.46	1.10	
		-66A Speed Grade	0.42	1.29	0.46	1.25	
		-66B Speed Grade	0.42	1.14	0.46	1.10	
		-75C Speed Grade	0.42	1.04	0.46	1.00	

Table 15: DC Input and Output Levels

Symbol	Parameter	Conditions	Min	Max	Unit
VIH	Input HIGH Voltage		0.5VCC	VCCIO+0.5	V
VIL	Input LOW Voltage		-0.5	0.3VCC	V
VOH	Output HIGH Voltage	IOH = -12 mA	2.4		V
		IOH = -500 mA	0.9VCC		V
VOL	Output LOW Voltage	IOL = 16 mA		0.45	V
		IOL = 1.5 mA		0.1VCC	V
II	I or I/O Input Leakage Current	VI = VCCIO or GND	-10	10	mA
IOZ	3-State Output Leakage Current	VI = VCCIO or GND	-10	10	mA
CI	Input Capacitance [a]			10	pF
IOS	Output Short Circuit Current [b]	VO = GND	-15	-180	mA
		VO = VCC	40	210	mA
ICC	D.C. Supply Current [c]	VI, VIO = VCCIO or GND	0.50 (typ)	4	mA
ICCIO	D.C. Supply Current on VCCIO		0	100	mA
Idd	Static Idd Current	See Figure 13			

- a. Capacitance is sample tested only.
- b. Only one output at a time. Duration should not exceed 30 seconds.
- c. For commercial grade devices only. Maximum ICC is 5 mA for all industrial grade devices. For AC conditions, contact QuickLogic Customer Engineering.

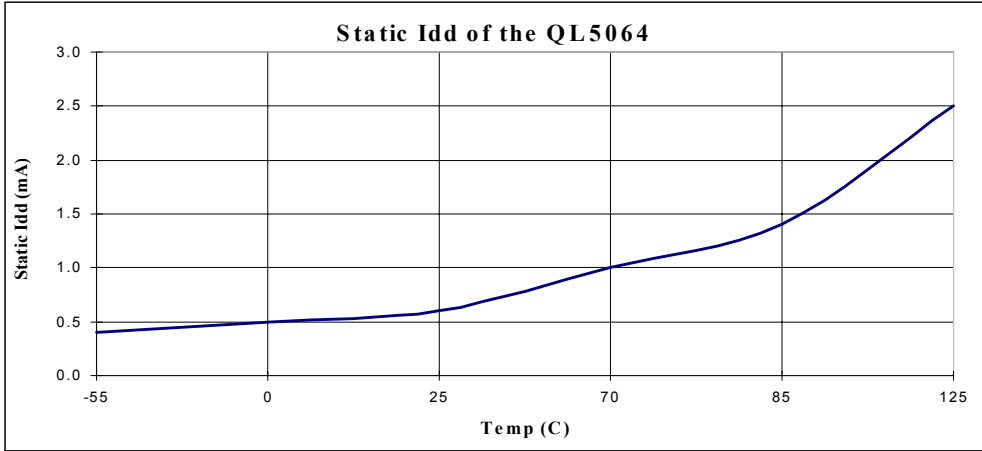

Figure 13: Static Idd of the QL5064

22.0 QL5064 Pin Type Descriptions

The QL5064 Device Pins are indicated in the table below. These are pins on the device, some of which connect to the PCI bus, and others that are programmable as user I/O.

Table 16: Pin Type Descriptions

Type	Description
IN	Input. A standard input-only signal
OUT	Totem pole output. A standard active output driver
T/S	Tri-state. A bi-directional, tri-state input/output pin
S/T/S	Sustained Tri-state. An active low tri-state signal driven by one PCI agent at a time. It must be driven high for at least one clock before being disabled (set to Hi-Z). A pull-up needs to be provided by the PCI system central resource to sustain the inactive state once the active driver has released the signal.
O/D	Open Drain. Allows multiple devices to share this pin as a wired-or.

NOTE: Signal names which end with the character ‘N’ should be considered active-low (for example, Mst_IRDYN).

Table 17: Pin / Bus Names and Functions

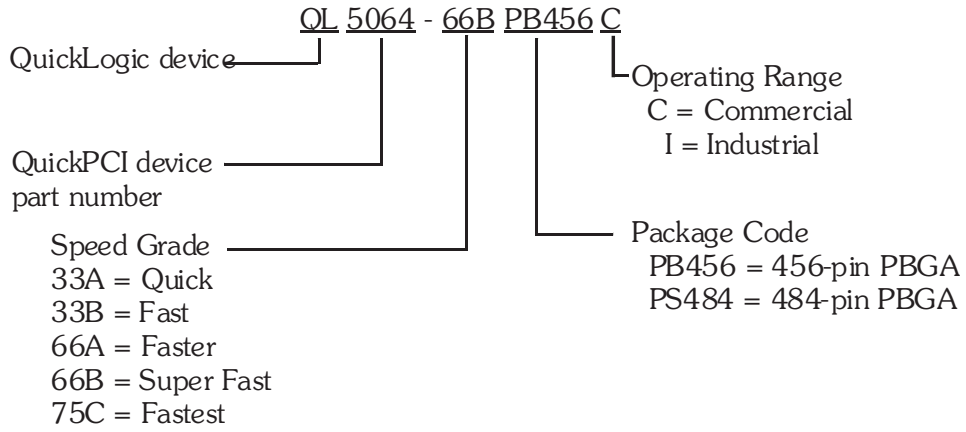

Pin/Bus Name	Type	Function
VCC	IN	Supply pin. Tie to 3.3V supply.
VCCIO	IN	Supply pin for I/O. Set to 3.3V for 3.3V I/O, 5V for 5.0V compliant I/O
GND	IN	Ground pin. Tie to GND on the PCB.
T/GND	IN	Thermal Ground. Used to dissipate heat from the device. Tie to GND on the PCB.
I/O	T/S	Programmable Input/Output/Tri-State/Bi-directional Pin.
I/GCLK	IN	Programmable Input-Only or Global Clock Pin. Tie to VCC or GND if unused.
I/ACLK	IN	Programmable Input-Only or Array Clock Pin. Tie to VCC or GND if unused.
TDI	IN	JTAG Data In. Tie to VCC if unused.
TDO	OUT	JTAG Data Out. Leave unconnected if unused.
TCL	IN	JTAG Clock. Tie to GND if unused.
TMS	IN	JTAG Test Mode Select. Tie to VCC if unused.
TRSTB	IN	JTAG Reset. Tie to GND if unused.
STM	IN	QuickLogic Reserved pin. Tie to GND on the PCB.
FLOAT	OUT	Test Data Out pin for QuickLogic use only. Must be isolated and floating at all times

23.0 QL5064 External Device Pins

Table 18: QL5064 External Device Pins

Pin/Bus Name	Type	Function
AD[63:0]	T/S	PCI Address and Data: 32 bit multiplexed address/data bus.
CBEN[7:0]	T/S	PCI Bus Command and Byte Enables: Multiplexed bus which contains byte enables for AD[31:0] or the Bus Command during the address phase of a PCI transaction.
PAR	T/S	PCI Parity: Even Parity across AD[31:0] and C/BEN[3:0] busses. Driven one clock after address or data phases. Master drives PAR on address cycles and PCI writes. The Target drives PAR on PCI reads.
PAR64	T/S	PCI Parity Upper DWORD: Even Parity across AD[63:32] and C/BEN[7:4] busses.
FRAMEN	S/T/S	PCI Cycle Frame: Driven active by current PCI Master during a PCI transaction. Driven low to indicate the address cycle, driven high at the end of the transaction.
REQ64N	S/T/S	PCI Request 64-bit transfer: Driven by the PCI Master to request a 64-bit transfer. Same signal timing as FRAMEN.
DEVSELN	S/T/S	PCI Device Select. Driven by a Target that has decoded a valid base address.
ACK64N	S/T/S	PCI Acknowledge 64-bit Transfer: Driven by a Target which has decoded a valid base address for a 64-bit data transfer. Same timing as DEVSELN.
CLK	IN	PCI System Clock Input.
RSTN	IN	PCI System Reset Input
REQN	T/S	PCI Request. Indicates to the Arbiter that this PCI Agent (Initiator) wishes to use the bus. A point to point signal between the PCI Device and the System Arbiter.
GNTN	IN	PCI Grant. Indicates to a PCI Agent (Initiator) that it has been granted access to the PCI bus by the Arbiter. A point to point signal between the PCI device and the System Arbiter.
PERRN	S/T/S	PCI Data Parity Error. Driven active by the initiator or target two clock cycles after a data parity error is detected on the AD and C/BEN busses.
SERRN	O/D	PCI System Error: Driven active when an address cycle parity error, data parity error during a special cycle, or other catastrophic error is detected.
IDSEL	IN	PCI Initialization Device Select. Use to select a specific PCI Agent during System Initialization.
IRDYN	S/T/S	PCI Initiator Ready. Indicates the Initiator's ability to complete a read or write transaction. Data transfer occurs only on clock cycles where both IRDYN and TRDYN are active.
TRDYN	S/T/S	PCI Target Ready. Indicates the Target's ability to complete a read or write transaction. Data transfer occurs only on clock cycles where both IRDYN and TRDYN are active.
STOPN	S/T/S	PCI Stop. Used by a PCI Target to end a burst transaction.
INTAN	O/D	Interrupt A. Asynchronous Active-Low Interrupt Request.

29.0 Revision History

Table 21: Revision History

Revision	Date	Comments
A	Sept 1999	First release.
B	March 2001	Update of electrical specs
C	Dec 2001	Re-formatted and re-organized for better clarity
D	Jan 2002	updated 484 pin table & added ordering info
