- 3.3V High Speed Bus Switching and Bus Isolation

DESCRIPTION:

The CBTLV3384 is a ten bit high-speed bus switch with low on-state resistance of the switch allowing connections to be made with minimal propagation delay.

The device is organized as dual 5-bit bus switches with separate output-enable (\overline{OE}) inputs, to allow use as two 5-bit bus switches or one 10-bit bus switch. When \overline{OE} is low, the associated 5-bit bus switch is on and A port is connected to B port. When \overline{OE} is high, the switch is open, and a high-impedance state exists between the two ports.

To ensure the high-impedance state during power up or power down, \overline{OE} should be tied to V_{CC} through a pullup resistor; the minimum value of the resistor is determined by the current-sinking capability of the driver.

NOTES:

- The increase in supply current is attributable to each current that is at the specified voltage level rather than V_{CC} or GND.
- This is measured by the voltage drop between the A and B terminals at the indicated current through the switch. On-state resistance is determined by the lower of the voltages of the two (A or B) terminals.
