### 2.5V and 3.3V LVCMOS Clock Distribution Buffer

## Features

- Configurable 10 outputs LVCMOS clock distribution buffer
- Compatible to single, dual and mixed $3.3 \mathrm{~V} / 2.5 \mathrm{~V}$ Voltage supply
- Wide range output clock frequency up to 250 MHz
- Designed for mid-range to high-performance telecom, networking and computer applications
- Supports applications requiring clock redundancy
- Max. output skew of 200 pS ( 150 pS within one bank)
- Selectable output configurations per output bank
- Tristatable outputs
- 32 lead LQFP \& TQFP Packages
- Ambient operating temperature range of -40 to $85^{\circ} \mathrm{C}$

## Functional Description

The ASM2199446 is a 2.5 V and 3.3 V compatible $1: 10$ clock distribution buffer designed for low-voltage mid-range to high-performance telecom, networking and computing applications. Both $3.3 \mathrm{~V}, 2.5 \mathrm{~V}$ and dual supply voltages are supported for mixed-voltage applications. The ASM2I99446 offers 10 low-skew outputs and 2 selectable inputs for clock redundancy. The outputs are configurable and support 1:1 and 1:2 output to input frequency ratios. The ASM2I99446
is specified for the extended temperature range of $-40^{\circ} \mathrm{C}$ to $85^{\circ} \mathrm{C}$.

The ASM2199446 is a full static fanout buffer design supporting clock frequencies up to 250 MHz . The signals are generated and retimed on-chip to ensure minimal skew between the three output banks. Two independent LVCMOS compatible clock inputs are available. This feature supports redundant clock sources or the addition of a test clock into the system design. Each of the three output banks can be individually supplied by 2.5 V or 3.3 V supporting mixed voltage applications. The FSELx pins choose between division of the input reference frequency by one or two. The frequency divider can be set individually for each of the three output banks. The ASM2I99446 can be reset and the outputs are disabled by deasserting the $M R / \overline{O E}$ pin (logic high state). Asserting MR/OE will enable the outputs.

All inputs accept LVCMOS signals while the outputs provide LVCMOS compatible levels with the capability to drive terminated $50 \Omega$ transmission lines. Please consult the ASM2I99456 specification for a 1:10 mixed voltage buffer with LVPECL compatible inputs. For series terminated transmission lines, each of the ASM2199446 outputs can drive one or two traces giving the devices an effective fanout of 1:20. The device is packaged in a $7 \times 7 \mathrm{~mm}^{2}$ 32-lead LQFP and TQFP Packages.

rev 0.4

## Driving Transmission Lines

The ASM2199446 clock driver was designed to drive high speed signals in a terminated transmission line environment. To provide the optimum flexibility to the user the output drivers were designed to exhibit the lowest impedance possible. With an output impedance of less than $20 \Omega$ the drivers can drive either parallel or series terminated transmission lines. In most high performance clock networks point-to-point distribution of signals is the method of choice. In a point-to-point scheme either series terminated or parallel terminated transmission lines can be used. The parallel technique terminates the signal at the end of the line with a $50 \Omega$ resistance to $\mathrm{V}_{\mathrm{Cc}} \div 2$.

This technique draws a fairly high level of DC current and thus only a single terminated line can be driven by each output of the ASM2199446 clock driver. For the series terminated case however there is no DC current draw, thus the outputs can drive multiple series terminated lines. Figure 3. "Single versus Dual Transmission Lines" illustrates an output driving a single series terminated line versus two series terminated lines in parallel. When taken to its extreme the fanout of the ASM2I99446 clock driver is effectively doubled due to its capability to drive multiple lines.

Figure 3. Single versus Dual Transmission Lines

The waveform plots in Figure 4. "Single versus Dual Line Termination Waveforms" show the simulation results of an output driving a single line versus two lines. In both cases the drive capability of the ASM2I99446 output buffer is more than sufficient to drive $50 \Omega$ transmission lines on the incident edge. Note from the delay measurements in the simulations a delta of only 43 pS exists between the two differently loaded outputs. This suggests that the dual line driving need not be used exclusively to maintain the tight output-to-output skew of the ASM2199446. The output waveform in Figure 4 "Single versus Dual Line Termination Waveforms" shows a step in the waveform. This step is caused by the
impedance mismatch seen looking into the driver. The parallel combination of the $36 \Omega$ series resistor plus the output impedance does not match the parallel combination of the line impedances. The voltage wave launched down the two lines will equal:
$V_{L}=V_{S}\left(Z_{0} \div\left(R_{S}+R_{0}+Z_{0}\right)\right)$
$Z_{0}=50 \Omega| | 50 \Omega$
$\mathrm{R}_{\mathrm{S}}=36 \Omega \| 36 \Omega$
$R_{0}=14 \Omega$
$V_{L}=3.0(25 \div(18+14+25))=1.31 V$
At the load end the voltage will double, due to the near unity reflection coefficient, to 2.5 V . It will then increment towards the quiescent 3.0 V in steps separated by one round trip delay (in this case 4.0nS).

Figure 4. Single versus Dual Waveforms
Since this step is well above the threshold region it will not cause any false clock triggering, however designers may be uncomfortable with unwanted reflections on the line. To better match the impedances when driving multiple lines the situation in Figure 5. "Optimized Dual Line Termination" should be used. In this case the series terminating resistors are reduced such that when the parallel combination is added to the output buffer impedance the line impedance is perfectly matched.

## Power Consumption of the ASM2I99446 and Thermal Management

The ASM2I99446 AC specification is guaranteed for the entire operating frequency range up to 250 MHz . The ASM2I99446 power consumption and the associated long-term reliability may decrease the maximum frequency limit, depending on operating conditions such as clock frequency, supply voltage, output loading, ambient temperature, vertical convection and thermal conductivity of package and board. This section describes the impact of these parameters on the junction temperature and gives a guideline to estimate the ASM2I99446 die junction temperature and the associated device reliability.

Table 11. Die junction temperature and MTBF

| Junction temperature $\left({ }^{\circ} \mathbf{C}\right)$ | MTBF (Years) |
| :---: | :---: |
| 100 | 20.4 |
| 110 | 9.1 |
| 120 | 4.2 |
| 130 | 2.0 |

Increased power consumption will increase the die junction temperature and impact the device reliability (MTBF). According to the system-defined tolerable MTBF, the die junction temperature of the ASM2I99446 needs to be controlled and the thermal impedance of the board/package should be optimized. The power dissipated in the ASM2199446 is represented in equation 1.

Where $\mathrm{I}_{\mathrm{CCQ}}$ is the static current consumption of the ASM2I99446, CPD is the power dissipation capacitance per output, (M) $\Sigma C_{L}$ represents the external capacitive output load, $N$ is the number of active outputs ( $N$ is always 12 in case of the ASM2199446). The ASM2I99446 supports driving transmission lines to maintain high signal integrity and tight timing parameters. Any transmission line will hide the lumped capacitive load at the end of the board trace, therefore, $\Sigma C_{L}$ is zero for controlled transmission line systems and can be eliminated from equation 1. Using parallel termination output termination results in equation 2 for power dissipation.

In equation 2, P stands for the number of outputs with a parallel or thevenin termination, $\mathrm{V}_{\mathrm{OL}}$, $\mathrm{l}_{\mathrm{oL}}, \mathrm{V}_{\text {он }}$ and Іон $^{\text {are }}$ a function of the output termination technique and $\mathrm{DC}_{\mathrm{Q}}$ is the clock signal duty cycle. If transmission lines are used $\Sigma C L$ is zero in equation 2 and can be eliminated. In general, the use of controlled transmission line techniques eliminates the impact of the lumped capacitive loads at the end lines and greatly reduces the power dissipation of the device. Equation 3 describes the die junction temperature $T_{J}$ as a function of the power consumption.

Where $R_{\text {thja }}$ is the thermal impedance of the package (junction to ambient) and $T_{A}$ is the ambient temperature. According to Table 11, the junction temperature can be used to estimate the long-term device reliability. Further, combining equation 1 and equation 2 results in a maximum operating frequency for the ASM2199446 in a series terminated transmission line system, equation 4.

\mathrm{f}_{\mathrm{CLOCK}, \mathrm{MAX}}=\frac{1}{\mathrm{C}_{\mathrm{PD}} \cdot \mathrm{~N} \cdot \mathrm{~V}_{\mathrm{CC}}^{2}} \cdot\left[\frac{\mathrm{~T}_{\mathrm{J}, \mathrm{MAX}}-\mathrm{T}_{\mathrm{A}}}{\mathrm{R}_{\mathrm{thja}}}-\left(\mathrm{I}_{\mathrm{CCQ}} \cdot \mathrm{~V}_{\mathrm{CC}}\right)\right]
\end{gathered}
$$

rev 0.4
$\mathrm{T}_{\mathrm{J}}, \mathrm{MAX}$ should be selected according to the MTBF system requirements and Table 11. $\mathrm{R}_{\text {thia }}$ can be derived from Table 12. The $\mathrm{R}_{\mathrm{th} \text { ja }}$ represent data based on 1S2P boards, using 2S2P boards will result in a lower thermal impedance than indicated below.
Table 12. Thermal package impedance of the 32LQFP

| Convection, <br> LFPM | $\mathbf{R}_{\text {thja }}$ (1P2S <br> board), ${ }^{\circ} \mathbf{C / W}$ | $\mathbf{R}_{\text {thja }}$ (2P2S <br> board), ${ }^{\circ} \mathbf{C / W}$ |
| :---: | :---: | :---: |
| Still air | 86 | 61 |
| 100 Ifpm | 76 | 56 |
| 200 lfpm | 71 | 54 |
| 300 lfpm | 68 | 53 |
| 400 lfpm | 66 | 52 |
| 500 lfpm | 60 | 49 |

If the calculated maximum frequency is below 350 MHz , it becomes the upper clock speed limit for the given application conditions. The following eight derating charts describe the safe frequency operation range for the ASM2I99446. The charts were calculated for a maximum tolerable die junction temperature of $110^{\circ} \mathrm{C}\left(120^{\circ} \mathrm{C}\right)$, corresponding to an estimated MTBF of 9.1 years (4 years), a supply voltage of 3.3 V and series terminated transmission line or capacitive loading. Depending on a given set of these operating conditions and the available device convection a decision on the maximum operating frequency can be made.
