## 8-PIN PWM SWITCHER CONTROLLERIC

## FEATURES

- 8-Pin SOIC switching controller with HICCUP current limiting reduces diode power dissipation to less than $1 \%$ of normal operation
- Soft-Start capacitor allows for smooth output voltage ramp up
- On-Board MOSFET Driver
- Fastest transient response of any controller method. (0 to 100\% Duty Cycle in 100ns)
- $1 \%$ Internal Voltage Reference
- Internal Under-Voltage Lockout protects MOSFET during start-up

## APPLICATIONS

- Dual supply low voltage processor applications, such as: P55C™ , CYRIX M2 ${ }^{\text {TM }}$, POWER PC ${ }^{\text {TM }}$ and AMD K6 ${ }^{\text {TM }}$
- Simple 5V to 3.3 V switcher for Pentium with AGP or Pentium II $^{\text {TM }}$ applications

## DESCRIPTION

The IRU3034 IC provides a low cost switching controller with true short circuit protection all in a compact 8-pin surface mount package, providing a low cost switching solution for dual supply processor applications that require switching regulator for the 3.3 V supply such as the applications with AGP on-board. Typically in these applications, a dual supply regulator converts 5 V to 3.3 V for I/O supply and a jumper programmable supply of 1.25 V to 3.5 V for CORE supply. The IC uses an internal regulator generated from the 12 V supply to power the controller as well as the 12 V supply to drive the power MOSFET, allowing a low cost N -channel MOSFET to be used. The IC also includes an error comparator for fast transient response, a precise voltage reference for setting the output voltage as well as a direct drive of the MOSFET for the minimum part count.

## TYPICAL APPLICATION

Figure 1 - Typical application of IRU3034.

## PIN DESCRIPTIONS

| PIN \# | PIN SYMBOL | PIN DESCRIPTION |
| :---: | :---: | :--- |
| 1 | DN | The PWM output of the switching controller. This pin is a totem pole drive that is con- <br> nected to the gate of the power MOSFET. A resistor may be placed from this pin to the <br> gate in order to reduce switching noise. |
| 2 | $V_{12}$ | This pin supplies the voltage to the PWM drive and hysteresis circuitry and it is connected <br> to the 12V supply. A 1 $\mu$ F, high frequency capacitor must be connected from this pin to <br> ground to provide the peak current for charging and discharging of the MOSFET. |
| 3 | $V_{\text {FB }}$ | A resistor divider from this pin to the output of the switching regulator and ground sets the <br> Core supply voltage. |
| 4 | $V_{\text {HYST }}$ | A resistor and a 10pF capacitor is connected from this pin to the VFB pin to set the output <br> ripple voltage for the switching regulator. |
| 5 | Gnd | This pin is connected to the IC substrate and must be connected to the lowest potential in <br> the system. |
| 6 | CS- | This pin is connected to the minus side of the external current sense resistor. An internal <br> current source together with an external resistor in series with this pin programs the <br> current limit threshold voltage. This voltage divided by the external current sense resistor <br> sets the current limit threshold. |
| 7 | CS+ | This pin is connected to the plus side of the external current sense resistor. A resistor in <br> series with this pin and a capacitor connected between this pin and pin 6 provides a high <br> frequency filtering for the noise spikes of turn on and turn off switching. |
| 8 | SS | This pin provides the soft-start for the regulator during power up. It also sets a long off time <br> when the converter goes into current limiting, providing low duty cycle for the catch diode <br> allowing it to survive during short circuit. |

## TYPICAL APPLICATION

5 V to 3.3 V with loss-less short circuit protection (Output UVLO detection)

Figure 5 - The circuit in figure 5 is designed to provide loss-less output short detection by detecting the DC voltage across the inductor and shutting down the MOSFET and entering HICCUP mode. Note that the current limit point is a function of the inductor resistance and in this application with approximately $8 \mathrm{~m} \Omega$ resistance the peak CL is set at 10A. See application note on how to set the current limiting threshold.

## APPLICATION INFORMATION

## Introduction

The IRU3034 device is an application specific product designed to provide an on-board switching supply for the new generation of microprocessors requiring separate Core and I/O supplies where the load current demand from the I/O supply requires this regulator to also be a switching regulator such as the motherboard applications with AGP slot or the Pentium II with on-board 5 V to 3.3 V converter. The IRU3034 provides an easy and low cost switching regulator solution for Vcore and 3.3 V supplies with true short circuit protection.

## Switching Controller Operation

The operation of the switching controller is as follows:
After the power is applied, the output drive pin (Drv) goes to $100 \%$ duty cycle and the current in the inductor charges the output capacitor causing the output voltage to increase. When output reaches a pre-programmed set point the feedback pin ( $\mathrm{V}_{\text {FB }}$ ) exceeds 1.25 V causing the output drive to switch Low and the VHyst pin to switch High which jumps the feedback pin higher than 1.25 V resulting in a fixed output ripple which is given by the following equation:

$$
\Delta \mathrm{Vo}=(\mathrm{Rt} / \mathrm{Rh}) \times 11
$$

Where:
$R t=$ Resistor connected from Vout to the $\mathrm{V}_{\text {FB }}$ pin of IRU3034.
Rh = Resistor connected from $\mathrm{V}_{\text {FB }}$ pin to $\mathrm{V}_{\text {нrst }}$ pin.
For example, if $\mathrm{Rt}=1 \mathrm{~K}$ and $\mathrm{Rh}=422 \mathrm{~K}$, then the output ripple is:

$$
\Delta \mathrm{Vo}=(1 / 422) \times 11=26 \mathrm{mV}
$$

The advantage of fixed output ripple is that when the output voltage changes from 2 V to 3.5 V , the ripple voltage remains the same which is important in meeting the Intel maximum tolerance specification.

## Soft-Start

The soft-start capacitor must be selected such that during the start-up when the output capacitors are charging up, the peak inductor current does not reach the current limit threshold. A minimum of $0.1 \mu \mathrm{~F}$ capacitor insures this for most applications. During start-up the soft-start capacitor is charged up to approximately 6 V keeping the output shutdown before an internal $10 \mu \mathrm{~A}$ current source start discharging the soft-start capacitor which
slowly ramps up the inverting input of the PWM comparator, Vfb. This insures the output to ramp up at the same rate as the soft-start cap thereby limiting the input current. For example, with $0.1 \mu \mathrm{~F}$ and the $10 \mu \mathrm{~A}$ internal current source the ramp up rate is:

$$
(\Delta \mathrm{V} / \Delta \mathrm{t})=\mathrm{I} / \mathrm{Css}=10 / 0.1=100 \mathrm{~V} / \mathrm{s} \text { or } 0.1 \mathrm{~V} / \mathrm{ms}
$$

Assuming that the output capacitance is $6000 \mu \mathrm{~F}$, the peak input current will be:

$$
\operatorname{liN(p\mathrm {p})}=\operatorname{Css} \times(\Delta \mathrm{V} / \Delta \mathrm{t})=6000 \mu \mathrm{~F} \times(0.1 \mathrm{~V} / \mathrm{ms})=0.6 \mathrm{~A}
$$

The soft start capacitor also provides a delay in the turn on of the output which is given by:

$$
T_{D}=\operatorname{Css} \times K
$$

Where:

$$
\mathrm{K}=30 \mathrm{~ms} / \mu \mathrm{F}
$$

For example for $\mathrm{Css}=0.1 \mu \mathrm{~F}$,

$$
T_{D}=0.1 \times 30=3 \mathrm{~ms}
$$

## Switcher Current Limit Protection

The IRU3034 uses an external current sensing resistor and compares the voltage drop across it to a programmed voltage which is set externally via a resistor ( RcL ) placed between the CS- terminal of the IC and Vout. Once the voltage across the sense resistor exceeds the threshold, the soft-start capacitor pulls up to 12 V , pulling up the inverting pin of the error comparator higher than noninverting which causes the external MOSFET to shut off. At this point the CS comparator changes its state and pulls the soft-start capacitor to Vcc which is 12 V and shutting the PWM drive. After the output drive is turned off, an internal $10 \mu \mathrm{~A}$ current source slowly discharges the soft-start capacitor to approximately 5.7 V , before the output starts to turn back on causing a long delay before the MOSFET turns back on. This delay causes the catch diode to cool off between the current limit cycles allowing the converter to survive a short circuit condition. An example is given below as how to select the current limiting components. Assuming the desired current limit point is set to be 20A and the current sense resistor $\mathrm{Rs}=5 \mathrm{~m} \Omega$, then the current limit programming resistor, Rcl is calculated as:

$$
\begin{aligned}
& \mathrm{Vcs}=\mathrm{IcL} \times \mathrm{Rs}=20 \times 0.005=0.1 \mathrm{~V} \\
& \mathrm{RcL}=\mathrm{Vcs} / \mathrm{IB}_{\mathrm{B}}=(0.1 \mathrm{~V}) /(20 \mu \mathrm{~A})=5 \mathrm{~K} \Omega
\end{aligned}
$$

Where:
$I_{B}=20 \mu \mathrm{~A}$ is the internal current source of IRU 3034

The peak power dissipated in the CS resistor is:

$$
\text { Ppk }=\left(\mathrm{IcL}^{2}\right) \times \mathrm{Rs}=20^{2} \times 0.005=2 \mathrm{~W}
$$

However, the average power dissipated is much lower than 2 W due to the long off time caused by the hiccup circuit of IRU3034. The average power is in fact the short circuit period divided by the short circuit period plus the off time or "hiccup" period. For example, if the short circuit lasts for Tsc=100 $\mu$ s before the IRU3034 enters hiccup, the average power is calculated as:

$$
\text { Pave }=0.5 \times \text { Ppk } \times \text { Dsc }
$$

Where:
Dsc = Tsc $/ \mathrm{T}_{\mathrm{HCP}}$
$\mathrm{T}_{\text {нср }}=\mathrm{Css} \times \mathrm{M}$
$\mathrm{M}=200 \mathrm{~ms} / \mu \mathrm{F}$
Css $=$ The soft-start capacitor
For example:
For Css $=0.1 \mu \mathrm{~F}$ and $\mathrm{Tsc}=500 \mu \mathrm{~s}=0.5 \mathrm{~ms}$
$\mathrm{T}_{\mathrm{HCP}}=0.1 \times 200=20 \mathrm{~ms}$
Pave $=0.5 \times 2 \times(0.5 / 20)=25 \mathrm{~mW}$
Without "hiccup" technique, the power dissipation of the resistor is 2 W .

## Switcher Output Voltage Setting

The output voltage can be set using the following equations:

Assuming, $\mathrm{Vo}=3.38 \mathrm{~V}$ and the selected output ripple is $\approx$ $1.3 \%(44 \mathrm{mV})$ of the output voltage, a set of equations are derived that selects the resistor divider and the hysteresis resistor:

Assuming, Rt $=1 \mathrm{~K} \Omega, 1 \%$ :

$$
\mathrm{R}_{\mathrm{H}}=(11 \times \mathrm{Rt}) / \Delta \mathrm{Vo}
$$

Where:
$R t=$ Top resistor of the resistor divider
$\mathrm{R}_{\mathrm{H}}=$ Hysteresis resistor connected between pins 3 and 4 of the IRU3034
$\Delta \mathrm{Vo}=$ Selected output ripple (typically $1 \%$ to $2 \%$ of output voltage)

Assuming, $\Delta \mathrm{Vo}=44 \mathrm{mV}$ :

$$
\mathrm{R}_{\mathrm{H}}=(11 \times 1000) / 0.044=250 \mathrm{~K} \Omega
$$

Select $\mathrm{R}_{\mathrm{H}}=249 \mathrm{~K} \Omega, 1 \%$

The bottom resistor of the divider is then calculated using the following equations:

$$
R_{B}=R t / X
$$

Where:
$R_{B}=$ Bottom resistor of the divider
$V_{\text {Ref }}=1.25 \mathrm{~V}$ Typical

$$
\begin{aligned}
& X=\left[(V o+(\Delta V o / 2)) / V_{R E F}\right]-1 \\
& X=[(3.38+(0.044 / 2)) / 1.25]-1=1.72 \\
& R_{B}=1000 / 1.72=580 \Omega
\end{aligned}
$$

Select $R_{B}=576 \Omega, 1 \%$

## Frequency Calculation

The IRU3034 frequency of operation is calculated using the following formula:

$$
\mathrm{Fs}=[(\mathrm{Vo} \times(1-\mathrm{D}) \times \mathrm{ESR})] /(\mathrm{L} \times \Delta \mathrm{Vo}) \quad(\mathrm{MHz})
$$

Where:
Vo = Output voltage (V)
D = Duty cycle
ESR = Output capacitor ESR (V)
$L=$ Output inductance ( $\mu \mathrm{H}$ )
$\Delta \mathrm{Vo}=$ Output ripple voltage (V)
For our example:

$$
D \approx\left(V_{o}+V_{f}\right) / V_{\text {IN }}
$$

Where:
$\mathrm{Vf}=$ Forward voltage drop of the Schottky diode.

$$
D=(3.38+0.5) / 5=0.78
$$

The $E S R=18 \mathrm{~m} \Omega$ for 2 of the Sanyo $1500 \mu \mathrm{~F}$, 6MV1500GX caps. If $L=3.5 \mu \mathrm{H}$ then, Fs is calculated as follows:

$$
F s=\frac{[(3.38 \times(1-0.78) \times 0.018)]}{(3.5 \times 0.044)}=0.087
$$

$\mathrm{Fs}=87 \mathrm{KHz}$
