# SIEMENS

# Decoder for Program Delivery Control and Video Program System PDC / VPS Decoder

# SDA 5648 SDA 5648X

**CMOS IC** 

# Features

- Single-chip receiver for PDC data, broadcast either – in Broadcast Data Service Packet (BDSP) 8/30/2
  - according to CCIR teletext system B, or
    in dedicated line no. 16 of the vertical blanking interval (VPS)
- Reception of Unified Date and Time (UDT) broadcast in BDSP 8/30/1
- Low external components count
- On-chip data and sync slicer
- I<sup>2</sup>C-Bus interface for communication with external microcontroller
- Selection of PDC/VPS operating mode software controlled by I<sup>2</sup>C-Bus register
- Pin and software compatible to VPS Decoder SDA 5642
- Supply voltage: 5 V ± 10 %
- Video input signal level: 0.7 Vpp to 1.4 Vpp
- Technology: CMOS
- Package: P-DIP-14-3 and P-DSO-20-1
- Operating temperature range: 0 to 70 °C

P-DIP	-14-3	

P-DSO-20-1

Туре	Ordering Code	Package
SDA 5648	Q67000-A5186	P-DIP-14-3
SDA 5648X	Q67006-A5198	P-DSO-20-1 Tape & Reel

### **Functional Description**

The CMOS circuit SDA 5648 is intended for use in video cassette recorders to retrieve control data of the PDC system from the data lines broadcast during the vertical blanking interval of a standard video signal.

The SDA 5648 is devised to handle PDC data transported either in Broadcast Data Service Packet (BDSP) 8/30 format 2 (bytes no. 13 through 25) of CCIR teletext system B or in the dedicated data line no. 16 in the case of VPS.

Furthermore it is able to receive the Unified Date and Time (UDT) information transmitted in bytes no. 15 through 21 of packet 8/30 format 1.

#### Pin Configuration

(top view)

Operating mode (PDC/VPS) is selected by a control register which can be written to via the I<sup>2</sup>C-Bus interface.

# **Pin Definitions and Functions**

Pin No. P-DIP-14-3	Pin No. P-DSO-20-1	Symbol	Function
1		V <sub>SS</sub>	Ground (0 V)
	1	V <sub>SSA</sub>	Analog ground (0 V)
	2	V <sub>SSD</sub>	Digital ground (0 V)
	3	N.C.	Not connected
2	4	SCL	Serial clock input of I <sup>2</sup> C-Bus.
3	5	SDA	Serial data input of I <sup>2</sup> C-Bus.
4	6	CS0	Chip select input determining the I <sup>2</sup> C-Bus addresses: $20_{H}$ / $21_{H}$ , when pulled low $22_{H}$ / $23_{H}$ , when pulled high.
5	7	VCS	Video Composite Sync output from sync slicer used for PLL based clock generation.
	8	N.C.	Not connected
6	9	DAVN	Data available output active low, when PDC/VPS data is received.
7	10	EHB	Output signaling the presence of the first field active high.
8	11	TI	Test input; activates test mode when pulled high.
9	12	PD1	Phase detector/charge pump output of data PLL (DAPLL).
	13	N.C.	Not connected
10	14	PD2/VCO2	Connector of the loop filter for the SYSPLL.
11	15	VCO1	Input to the voltage controlled oscillator #1 of the DAPLL.
12	16	I <sub>REF</sub>	Reference current input for the on-chip analog circuit.
13	17	CVBS	Composite video signal input.
	18	N.C.	Not connected
14		V <sub>DD</sub>	Positive supply voltage (+ 5 V nom.).
	19	V <sub>DDD</sub>	Positive supply voltage for the digital circuits (+ 5 V nom.).
	20	V <sub>DDA</sub>	Positive supply voltage for the analog circuits (+ 5 V nom.).

# Block Diagram

#### **Circuit Description**

Referring to the functional block diagram of the PDC / VPS decoder, the composite video signal with negative going sync pulses is coupled to the pin CVBS through a capacitor which is used for clamping the bottom of the sync pulses to an internally fixed level. The signal is passed on to the slicer, an analog circuitry separating the sync and the data parts of the CVBS signal, thus yielding the digital composite sync signal VCS and a digital data signal for further processing by comparing those signals to internally generated slicing levels.

The output of the sync separator is forwarded, on one hand, to the output pin VCS, and on the other hand, to the clock generator and the Timing block. The VCS signal represents a key signal that is used for deriving a system clock signal by means of a PLL.

The data slicer separates the data signal from the CVBS signal by comparing the video voltage to an internally generated slicing level which is found by averaging the data signal during TV line no. 16 in the VPS mode or by averaging the data signal during the clock run-in period of the teletext lines during the data entry window (DEW) in PDC mode.

The clock generator delivers the system clock needed for the basic timing as well as for the regeneration of the data clock. It is based on two phase locked loops (PLL's) all parts of which are integrated on chip with the exception of the loop filter components. Each of the PLL's is composed of a voltage controlled oscillator (VCO), a phase/frequency detector (PFD), and a charge pump which converts the digital output signals of the PFD to an analog current. That current is transformed to a control voltage for the VCO by the off-chip loop filter. The generated VCO frequencies are 10 MHz and 13.875 MHz for VPS mode and PDC mode, respectively.

All signals necessary for the control of sync and data slicing as well as for the data acquisition are generated by the Timing block.

In PDC mode, only teletext rows 8/30 containing Broadcast Data Service Package (BDSP) information are acquired. The relevant bytes of 8/30 format 1 (8/30/1) and 8/30 format 2 (8/30/2) are extracted. The 8/30/1-bytes are stored in the acquisition register in a transparent way without any bit manipulation, whereas the Hamming coded bytes of packet 8/30/2 are Hamming-checked and bytes with one bit error are corrected. The storage of error free or corrected 8/30/2-data bytes in the transfer register to the I<sup>2</sup>C-Bus is signalled by the DAVN output going low. The reception and storage of 8/30/1- data, however, is not indicated by the DAVN output. The presence of 8/30/1 data can only be checked by polling the data register via the I<sup>2</sup>C-Bus.

In VPS mode, the extracted data bits of TV line no. 16 are checked for biphase errors. With no biphase errors encountered, the acquired bytes are stored in the transfer register to the I<sup>2</sup>C-Bus. That transfer is signalled by a H/L transition of the DAVN output, as well.

In both operating modes data are updated when a new data line has been received, provided that the chip is not accessed via the I<sup>2</sup>C-Bus at the same time.

A micro controller can read the stored bytes via the I<sup>2</sup>C-Bus interface at any time. However, one must be aware that the storage of new data from the acquisition interface is inhibited as long as the PDC decoder is being accessed via the I<sup>2</sup>C-Bus. At the end of an I<sup>2</sup>C-Bus reading the transfer registers are set to FF (hex) until they are updated by the reception of new data packet contained in the CVBS signal.

#### I<sup>2</sup>C-Bus

#### **General Information**

The I<sup>2</sup>C-Bus interface implemented on the PDC decoder is a slave transmitter/receiver, i.e., both reading from and writing to the PDC / VPS decoder is possible. The clock line SCL is controlled only by the bus master usually being a micro controller, whereas the SDA line is controlled either by the master or by the slave. A data transfer can only be initiated by the bus master when the bus is free, i.e., both SDA and SCL lines are in a high state. As a general rule for the I<sup>2</sup>C-Bus, the SDA line changes state only when the SCL line is low. The only exception to that rule are the Start Condition and the Stop Condition. Further details are given below. The following abbreviations are used:

START :	Start Condition generated by master
AS :	Ackknowledge by slave
AM :	Ackknowledge by master
NAM :	No Ackknowledge by master
STOP :	Stop Condition generated by master

#### **Chip Address**

There are two pairs of chip addresses, which are selected by the CS0-input pin according to the following table

CS0 Input	Write Mode	Read Mode
Low	20 (hex)	21 (hex)
High	22 (hex)	23 (hex)

#### Write Mode

For writing to the PDC decoder, the following format has to be used:

START	Chipadress White Mode	AS	Byte Set Control Register	AS	STOP	
-------	-----------------------	----	---------------------------	----	------	--

#### Data Transfer (Write Mode)

- *Step1*: In order to start a data transfer the master generates a Start Condition on the bus by pulling the SDA line low while the SCL line is held high.
- Step 2: The bus master puts the chip address on the SDA line during the next eight SCL pulses.
- *Step 3*: The master releases the SDA line during the ninth clock pulse. Thus the slave can generate an acknowledge (AS) by pulling the SDA line to a low level.
- Step 4: The controller transmits the data byte to set the Control register.
- *Step 5*: The slave acknowledges the reception of the byte.
- Step 6: The master concludes the data communication by generating a Stop Condition.

The write mode is used to set the I<sup>2</sup>C-Bus control register which determines the operating mode:

#### **Control Register**

Bit Number	7	6	5	4	3	2	1	0
	T4	Т3	T2	T1	то	DIS	PDC/ VPS	FOR1/ FOR2

Default: All bits are set to 0 on power-up.

Value				
0	1			
BDSP	BDSP 8/ 30/ 1 or			
8/ 30/ 2	header row			
data accessible	data accessible (refer to description of Bit 2)			

#### Bit 1: Determines the operating mode.

Value				
0	1			
VPS mode active	PDC mode active			

Bits 2 through 7 are used for test purposes.

DIS: Don't care.

Bits 3 through 7 must not be changed for normal operation by user software!

#### Read Mode

For reading from the PDC decoder, the following format has to be used.

START	Chipaddress Read Mode	AS	1st Byte	AM	 Last Byte	NAM	STOP
					Dyic		

#### Data Transfer (Read Mode)

- *Step1*: To start a data transfer the master generates a Start Condition on the bus by pulling the SDA line low while the SCL line is held high. The byte address counter in the decoder is reset and points to the first byte to be output.
- Step 2: The bus master puts the chip address on the SDA line during the next eight SCL pulses.
- Step 3: The master releases the SDA line during the ninth clock pulse. Thus the slave can generate an acknowledge (AS) by pulling the SDA line to a low level. At this moment, the slave switches to transmitting mode.
- Step 4: During the next eight clock pulses the slave puts the addressed data byte onto the SDA line.
- Step 5: The reception of the byte is acknowledged by the master device which, in turn, pulls down the SDA line during the next SCL clock pulse. By acknowledging a byte, the master prompts the slave to increment its internal address counter and to provide the output of the next data byte.
- Step 6: Steps no. 4 and no. 5 are repeated, until the desired amount of bytes have been read.
- Step 7: The last byte is output by the slave since it will not be acknowledged by the master.
- Step 8: To conclude the read operation, the master doesn't acknowledge the last byte to be received. A No Acknowledge by the master (NAM) causes the slave to switch from transmitting to receiving mode. Note that the master can prematurely cease any reading operation by not acknowledging a byte.
- Step 9: The master gains control over the SDA line and concludes the data transfer by generating a Stop Condition on the bus, i. e., by producing a low/high transition on the SDA line while the SCL line is in a high state. With the SDA and the SCL lines being both in a high state, the I<sup>2</sup>C-Bus is free and ready for another data transfer to be started.

The contents of up to 7 registers (bytes) can be read starting with byte 1 bit 7 (refer to the following table).

t

# **Description of DAVN and EHB Outputs**

DAVN (Data Valid active low)

EHB (First Field active high)

Signal Output	VPS Mode	PDC Mode						
		8/30/2	8/30/1					
DAVN								
H/L-transition (set low)	in line 16 when valid VPS data is received	in the line carrying valid 8/30/2 data	in the line carrying valid 8/30/1 data					
L/H-transition (set high)	at the start of line 16	at the beginning of the next field i.e.,at the start of the next data entry windo						
always set high	on power-up or during I <sup>2</sup> C-Bus acc acknowledge in or		bus master doesn't he stop condition					
EHB								
L/H-transition	at the beginning o	f the first field						
H/L-transition	at the beginning o	at the beginning of the second field						

In test mode (i.e. TI = high), both DAVN and EHB are controlled by the CS0 pin and reproduce the state of the CS0 input.
