

Dual Regulators - Synchronous Buck PWM DC-DC and Linear Controller

General Description

The RT9205/A is a dual-output power controllers designed for high performance graphics cards and personal computers. The IC integrates a synchronous buck controller, a linear controller and protection functions into a small 14-pin package.

The RT9205/A uses an internal compensated voltage mode PWM control for simplifying design. An internal 0.8V reference allows the output voltage to be precisely regulated to meet low output voltage requirement. A fixed 300kHz oscillation frequency reduces the component size for saving board area.

The RT9205/A also features over voltage protection (OVP) and under voltage lock-out (UVLO).

Applications

- PC Motherboard
- Cable Modems, Set-Top-Box, and XDSL Modems
- DSP and Core Communications Processor Supplies
- Memory Power Supplies
- Personal Computer Peripherals
- Industrial Power Supplies
- 5V Input DC-DC Regulators
- Low Voltage Distributed Power Supplies
- Graphic Cards

Features

- Operates at 5V
- 0.8V Internal Reference
- Drives Two N-channel MOSFET
- Voltage Mode PWM Control
- Fast Transient Response
- Fixed 300kHz Oscillator Frequency
- Dynamic 0~100% Duty Cycle
- Internal PWM Loop Compensation
- Internal Soft-Start
- Adaptive Non-overlapping Gate Driver
- Over-voltage Protection Uses Lower MOSFET

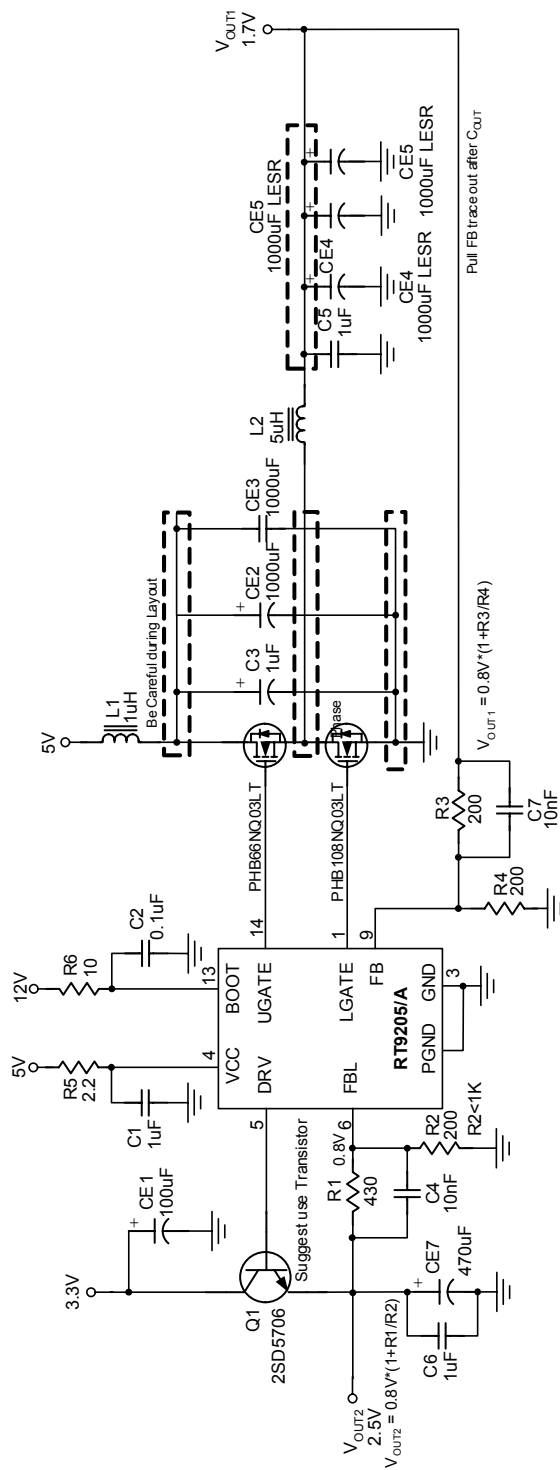

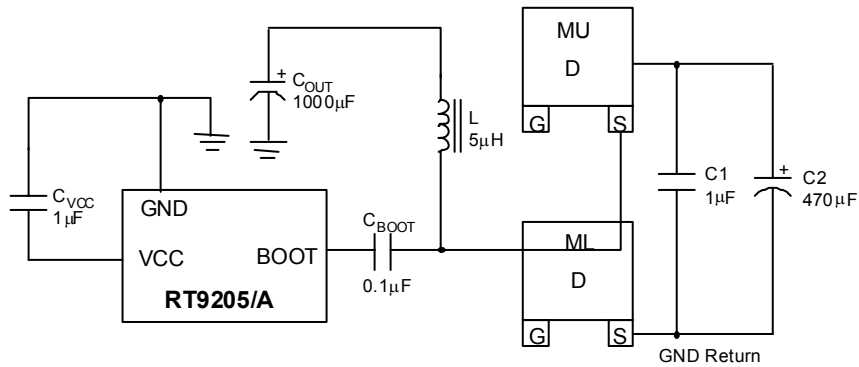

Fig.2 RT9205/A powered from 12V

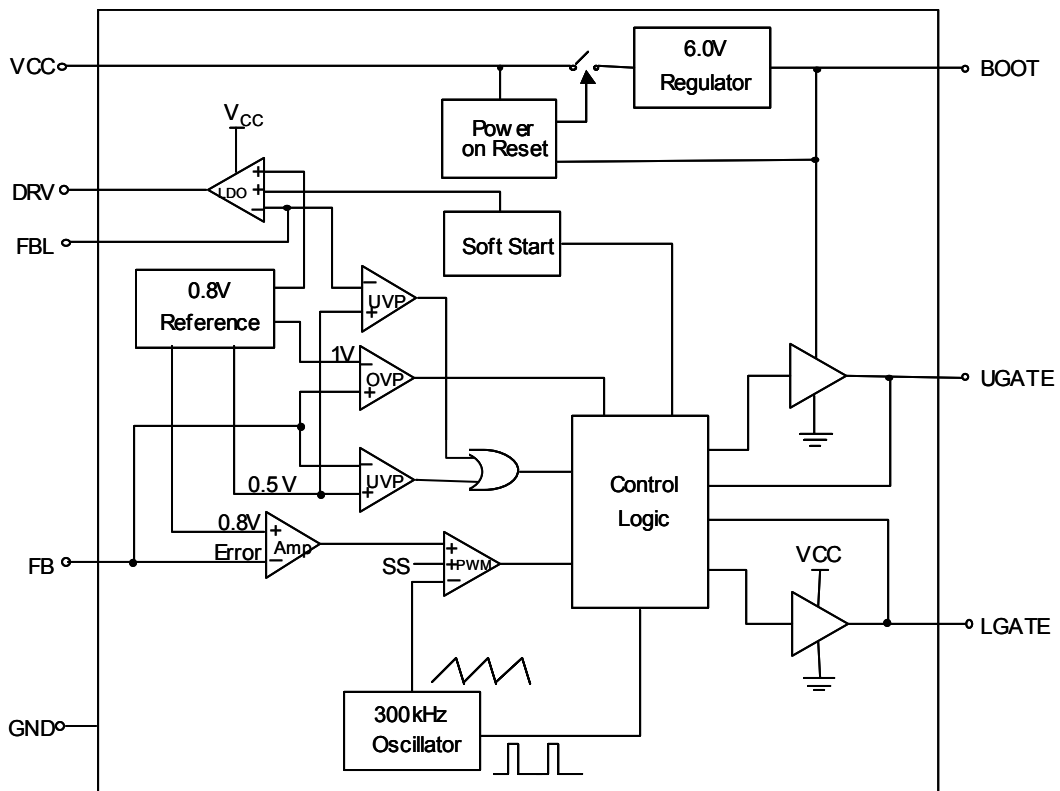

Layout Placement

Layout Notes

1. Put C1 & C2 to be near the MU drain and ML source nodes.
2. Put RT9205/A to be near the C_{OUT}
3. Put C_{BOOT} as close as to BOOT pin
4. Put C_{VCC} as close as to VCC pin

Function Block Diagram

Absolute Maximum Ratings

- Supply Voltage VCC 7V
- BOOT & UGATE to GND 19V
- Input, Output or I/O Voltage GND-0.3V ~ 7V
- Package Thermal Resistance
SOP-14, θ_{JA} 160°C/W
- Ambient Temperature Range 0°C ~ +70°C
- Junction Temperature Range -40°C ~ +125°C
- Storage Temperature Range -65°C ~ +150°C
- Lead Temperature (Soldering, 10 sec.) 260°C

CAUTION:

Stresses beyond the ratings specified in “Absolute Maximum Ratings” may cause permanent damage to the device. This is a stress only rating and operation of the device at these or any other conditions above those indicated in the operational sections of this specification is not implied.

Functional Pin Description

LGATE (Pin 1)

Connect the LGATE pin to the gate of lower MOSFET. This pin provides the gate drive for the lower MOSFET.

PGND/GND (Pin 2, 3)

Signal and power ground for the IC. All voltage levels are measured with respect to this pin.

VCC (Pin 4)

This is the main bias supply for the RT9205/A. This pin also provides the gate bias charge for the gate of lower MOSFET. The voltage at this pin is monitored for ensuring a proper power-on reset (POR). This pin is also the out of an internal 6.0V regulator that powered from the BOOT pin when the BOOT pin is directly powered from ATX 12V.

DRV (Pin 5)

This pin is the output of a linear controller. It should be connected to the base of an external bypass NPN transistor or the gate of a N-MOSFET to form a linear low dropout regulator.

FBL (Pin 6)

This pin is connected to the output resistor-divider of an external power transistor or a N-MOSFET based low dropout regulator for regulating and monitoring the output voltage. This pin is also connected to the protection monitor and the inverting input of error amplifier of internal linear regulator inside the IC.

FB (Pin 9)

This pin is connected to the PWM converter's output – divider for regulating and monitoring the output voltage of buck converter. This pin also connects to the protection monitor and the inverting input of internal PWM error amplifier inside the IC.

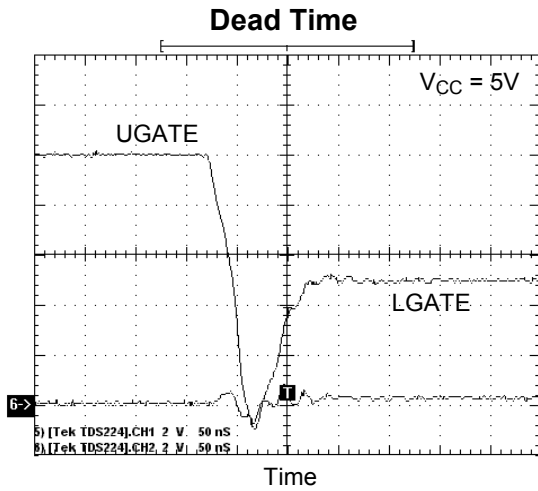

BOOT (Pin 13)

This pin provides ground referenced bias voltage to the upper MOSFET driver. A bootstrap circuit is used to create a voltage that is suitable for driving a logic-level N-channel MOSFET when operating at a single 5V power supply. This pin also could be powered from ATX 12V, in this situation, an internal 6.0V regulator will supply to VCC pin for generating bias required inside the IC.

UGATE (Pin 14)

Connect the UGATE pin to the gate of upper MOSFET. This pin provides the gate drive for the upper MOSFET.

POR (Rising/Falling) vs. Temperature

Functional Description

The RT9205/A operates at either single 5V power supply with a bootstrap UGATE driver or a 5V/12V dual-power supply form the ATX SMPS. The dual-power supply is recommended for high current applications, the RT9205/A can deliver higher gate driving current while operating with ATX SMPS based on a dual-power supply.

The Bootstrap Operation

In a single power supply system, the UGATE driver of RT9205/A is powered by an external bootstrap circuit, as shown in the Fig.3. The boot capacitor, C_{BOOT} , generates a floating reference at the PHASE pin. Typically a $0.1\mu F$ C_{BOOT} is enough for most of MOSFETs used with the RT9205/A. The voltage drop between BOOT and PHASE is refreshed to a voltage of $V_{CC} - \text{diode drop } (V_D)$ while the lower MOSFET turning on.

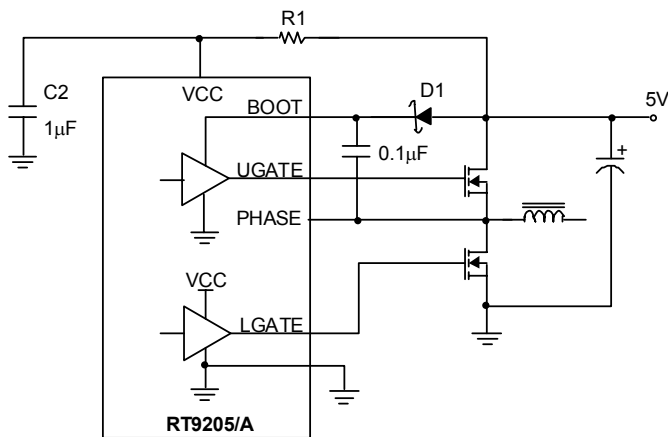

Fig.3 Single 5V power Supply Operation

Dual Power Operation

The RT9205/A was designed to supply a regulated 6.0V at VCC pin automatically when BOOT pin is powered by a 12V. In a system with ATX 5V/12V power supply, the RT9205/A is ideal for higher current applications due to the higher gate driving capability, $V_{UGATE} = 12V$ and $V_{LGATE} = 6.0V$. A RC ($10\Omega/1\mu F$) filter is also recommended at BOOT pin to prevent the ringing induced from fast power-on, as shown in Fig.4.

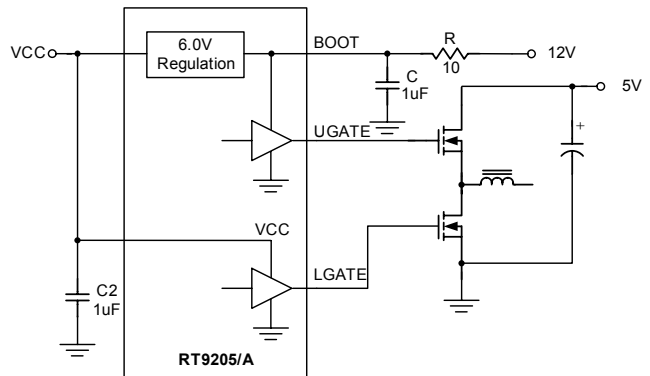

Fig.4 Dual Power Supply Operation

Power On Reset

The Power-On Reset (POR) monitors the supply voltage (normal +5V) at the VCC pin and the input voltage at the OCSET pin. The VCC POR level is set to 4.1V with 0.5V hysteresis and the normal level at OCSET pin is set to 1.5V (see over-current protection). The POR function initiates soft-start operation after all supply voltages exceed their POR thresholds.

Soft Start

A built-in soft-start is used to prevent surge current from power supply input during powering on. The soft-start voltage is controlled by an internal digital counter. It slows down and clamps the ramping of reference voltage at the input of error amplifier and the pulse-width of the output driver. The typical soft-start duration is 2.5mS.

Under Voltage and Over Voltage Protection

The voltage presents at FB pin is monitored and protected against OC (over current), UV (under voltage), and OV (over voltage). The UV threshold is 0.56V and OV-threshold is 1.0V. Both UV and OV detection are with $30\mu S$ delay after triggered. When OC or UV triggered, a hiccup re-start sequence will be initialized, as shown in Fig.5. For RT9205, only 3 times of trigger are allowed before latching off. But for RT9205A, UVP will be kept in hiccup mode. Hiccup is disabled during soft-start interval.

Fig. 5

Applications Information

Inductor Selection

The RT9205/A was designed for $V_{IN} = 5V$, step-down application mainly. Fig.6 shows the typical topology and waveforms of step-down converter.

The ripple current of inductor can be calculated as follows:

$$I_{L\text{RIPPLE}} = (5V - V_{OUT})/L \times T_{ON}$$

Because operation frequency is fixed at 300kHz,

$$T_{ON} = 3.33 \times V_{OUT}/5V$$

The V_{OUT} ripple is

$$V_{OUT\text{RIPPLE}} = I_{L\text{RIPPLE}} \times ESR$$

ESR is the equivalent series resistor of output capacitor

Table 1 shows the ripple voltage of V_{OUT} at $V_{IN} = 5V$

Table 1

V_{OUT}	3.3V		2.5V		1.5V	
Inductor	2 μ H	5 μ H	2 μ H	5 μ H	2 μ H	5 μ H
1000 μ F (ESR=53m Ω)	100mV	40mV	110mV	44mV	93mV	37mV
1500 μ F (ESR=33m Ω)	62mV	25mV	68mV	28mV	58mV	23mV
3000 μ F (ESR=21m Ω)	40mV	16mV	43mV	18mV	37mV	15mV

*Refer to Sanyo low ESR series (CE, DX, PX...)

The suggested L and C are as follows:

2 μ H with $\geq 1500\mu$ F C_{OUT}

5 μ H with $\geq 1000\mu$ F C_{OUT}

C.C.M.

Fig. 6

Input / Output Capacitor

High frequency/long life decoupling capacitors should be placed as close to the power pins of the load as physically possible. Be careful not to add inductance to the PCB trace, as it could eliminate the performance from utilizing these low inductance components. Consult with the manufacturer of the load on specific decoupling requirements.

The output capacitors are necessary for filtering output and stabilizing the close loop (see the PWM loop stability). For powering advanced high-speed processors, it is required to meet fast load transient requirement. Also high ESR usually induces ripple that may trigger UV or OV protections. So High frequency capacitors with low ESR/ESL capacitors are recommended here.

Linear Regulator Driver

The linear controller of RT9205/A was designed to drive an external bipolar NPN transistor or a N-channel MOSFET. For a N-channel MOSFET, normally DRV need to provide minimum $V_{OUT2} + V_T + \text{gate-drive voltage}$ to keep V_{OUT2} as the set voltage. When driving MOSFET operating at a 5V power supply, the gate-drive will be limited at 5V. At this situation, as shown in Fig.7, a MOSFET with low V_T threshold ($V_T = 1V$) and set V_{out2} below 2.5V are suggested. In $V_{BOOT} = 12V$ operation condition, as Fig.8 shown, VCC is regulated higher than 6V, which providing higher gate-drive capability for driving the MOSFET, V_{OUT2} can be set as $V_{OUT2} \leq 3.3V$.

Fig. 7

Fig. 8

PWM Loop Stability

The RT9205/A is a voltage mode buck controller designed for 5V step-down applications. The gain of error amplifier is fixed at 35dB for simplifying design.

The output amplitude of ramp oscillator is 1.6V, the loop gain and loop pole/zero are calculated as follows:

$$DC \text{ loop gain } G_A = 35dB \times \frac{5}{1.75} \times \frac{0.8}{V_{OUT}}$$

$$LC \text{ filter pole } P_O = \frac{1}{2\pi \sqrt{LC}}$$

$$\text{Error Amp pole } P_A = 300kHz$$

$$\text{ESR zero } Z_O = \frac{1}{2\pi ESR \times C}$$

The RT9205/A Bode plot is as shown in Fig.9. It is stable in most of application conditions.

Fig. 9

Reference Voltage

Because RT9205/A uses a low 35dB gain error amplifier, as shown in Fig.10. The voltage regulation is dependent on V_{IN} and V_{OUT} settings. The FB reference voltage of 0.8V were trimmed at $V_{IN} = 5V$ and $V_{OUT} = 2.5V$. In a fixed $V_{IN} = 5V$ application, the FB reference voltage vs. V_{OUT} voltage can be calculated as Fig.11.

Fig. 10

Fig. 12

PWM Layout Considerations

MOSFETs switch very fast in efficiency. The speed with which the current transitions from one device to another causes voltage spikes across the interconnecting impedances and parasitic circuit elements. The voltage spikes can degrade efficiency and radiate noise, that results in over-voltage stress on devices. Careful the layout for component placement layout and printed circuit design can minimize the voltage spikes induced in the converter. Consider, as an example, the turn-off transition of the upper MOSFET prior to turn-off, the upper MOSFET was carrying the full load current. During turn-off, current stops flowing in the upper MOSFET and is picked up by the lower MOSFET or Schottky diode. Any inductance in the switched current path generates a large voltage spike during the switching interval. Care with component selections, layout of the critical components, and use shorter and wider PCB traces that help in minimizing the magnitude of voltage spikes.

There are two sets of critical components in a DC-DC converter using the RT9205/A. The switching power components are most critical because they switch large amounts of energy, and as such, they tend to generate equally large amounts of noise. The critical small signal components are those connected to sensitive nodes or those supplying critical bypass current.

The power components and the PWM controller should be placed firstly. Place the input capacitors, especially the high-frequency ceramic decoupling capacitors, close to the power switches. Place the output inductor and output capacitors between the

Fig. 11

Feedback Divider

The reference of RT9205/A is 0.8V. The output voltage can be set using a resistor-divider as shown in Fig.12. Put the R1 and R2 as close as possible to FB pin. R2 value should be less than 1 kΩ to avoid noise coupling issue. The C1 capacitor is a speed-up capacitor for reducing output ripple to meet with the requirement of fast transient load. Typically, value between 1nF and 0.1μF is enough for C1.

MOSFETs and the load. Also locate the PWM controller near by MOSFETs.

A multi-layer printed circuit board is recommended. Fig.13 shows the connections of the critical components in the converter. Note that the capacitors CIN and COUT represent numerous physical capacitors. Use a dedicated grounding plane and use vias to ground all critical components to this layer. Apply another solid layer as a power plane and cut this plane into smaller islands of common voltage levels. The power plane should support the input power and output power nodes. Use copper filled polygons on the top and bottom circuit layers for the PHASE node, but it is not necessary to oversize this particular island. Since the PHASE node is subjected to very high dV/dt voltages, the stray capacitance formed between these islands and the surrounding circuitry will tend to couple switching noise. Use the remaining printed circuit layers for small signal routing. The PCB traces between the PWM controller and the gate of MOSFET and also the traces connecting source of MOSFETs should be sized to carry 2A peak currents.
