

Dual Synchronous Rectified MOSFET Drivers

The ISL6610, ISL6610A integrates two ISL6609, ISL6609A drivers with enable function removed and is optimized to drive two independent power channels in a synchronous-rectified buck converter topology. These drivers, combined with an Intersil ISL63xx or ISL65xx multiphase PWM controller, form a complete high efficiency voltage regulator at high switching frequency.

The IC is biased by a single low voltage supply (5V), minimizing driver switching losses in high MOSFET gate capacitance and high switching frequency applications. Each driver is capable of driving a 3nF load with less than 10ns rise/fall time. Bootstrapping of the upper gate driver is implemented via an internal low forward drop diode, reducing implementation cost, complexity, and allowing the use of higher performance, cost effective N-Channel MOSFETs. Adaptive shoot-through protection is integrated to prevent both MOSFETs from conducting simultaneously.

The ISL6610, ISL6610A features 4A typical sink current for the lower gate driver, enhancing the lower MOSFET gate hold-down capability during PHASE node rising edge, preventing power loss caused by the self turn-on of the lower MOSFET due to the high dV/dt of the switching node.

The ISL6610, ISL6610A also features an input that recognizes a high-impedance state, working together with Intersil multiphase PWM controllers to prevent negative transients on the controlled output voltage when operation is suspended. This feature eliminates the need for the schottky diode that may be utilized in a power system to protect the load from negative output voltage damage.

In addition, the ISL6610As bootstrap function is designed to prevent the BOOT capacitor from overcharging, should excessively large negative swings occur at the transitions of the PHASE node.

Applications

- Core Voltage Supplies for Intel® and AMD® Microprocessors
- High Frequency Low Profile High Efficiency DC/DC Converters
- High Current Low Voltage DC/DC Converters
- Synchronous Rectification for Isolated Power Supplies

Features

- 5V Quad N-Channel MOSFET Drives for Two Synchronous Rectified Bridges
- Pin-to-pin Compatible with ISL6614 (12V Drive)
- Adaptive Shoot-Through Protection
- 0.4Ω On-Resistance and 4A Sink Current Capability
- Supports High Switching Frequency
 - Fast Output Rise and Fall
 - Low Tri-State Hold-Off Time
- BOOT Capacitor Overcharge Prevention (ISL6610A)
- Low V_F Internal Bootstrap Diode
- Power-On Reset
- QFN Package
 - Compliant to JEDEC PUB95 MO-220 QFN-Quad Flat No Leads-Product Outline
 - Near Chip-Scale Package Footprint; Improves PCB Utilization, Thinner Profile
- Pb-Free Plus Anneal Available (RoHS Compliant)

Functional Pin Description

PACKAGE PIN #		PIN SYMBOL	FUNCTION
SOIC	DFN		
1	15	PWM1	The PWM signal is the control input for the Channel 1 driver. The PWM signal can enter three distinct states during operation, see the Tri-state PWM Input section under DESCRIPTION for further details. Connect this pin to the PWM output of the controller.
2	16	PWM2	The PWM signal is the control input for the Channel 2 driver. The PWM signal can enter three distinct states during operation, see the Tri-state PWM Input section under DESCRIPTION for further details. Connect this pin to the PWM output of the controller.
3	1	GND	Bias and reference ground. All signals are referenced to this node.
4	2	LGATE1	Lower gate drive output of Channel 1. Connect to gate of the low-side power N-Channel MOSFET.
5	3	PVCC	This pin supplies power to both the lower and higher gate drives. Place a high quality low ESR ceramic capacitor from this pin to PGND.
6	4	PGND	Power ground return of both low gate drivers.
-	5,8	NC1,2	No connection.
7	6	LGATE2	Lower gate drive output of Channel 2. Connect to gate of the low-side power N-Channel MOSFET.
8	7	PHASE2	Connect this pin to the SOURCE of the upper MOSFET and the DRAIN of the lower MOSFET in Channel 2. This pin provides a return path for the upper gate drive.
9	9	UGATE2	Upper gate drive output of Channel 2. Connect to gate of high-side power N-Channel MOSFET.
10	10	BOOT2	Floating bootstrap supply pin for the upper gate drive of Channel 2. Connect the bootstrap capacitor between this pin and the PHASE2 pin. The bootstrap capacitor provides the charge to turn on the upper MOSFET. See the Internal Bootstrap Device section under DESCRIPTION for guidance in choosing the capacitor value.
11	11	BOOT1	Floating bootstrap supply pin for the upper gate drive of Channel 1. Connect the bootstrap capacitor between this pin and the PHASE1 pin. The bootstrap capacitor provides the charge to turn on the upper MOSFET. See the Internal Bootstrap Device section under DESCRIPTION for guidance in choosing the capacitor value.
12	12	UGATE1	Upper gate drive output of Channel 1. Connect to gate of high-side power N-Channel MOSFET.
13	13	PHASE1	Connect this pin to the SOURCE of the upper MOSFET and the DRAIN of the lower MOSFET in Channel 1. This pin provides a return path for the upper gate drive.
14	14	VCC	Connect this pin to a +5V bias supply. It supplies power to internal analog circuits. Place a high quality low ESR ceramic capacitor from this pin to GND.
-	17	PAD	Connect this pad to the power ground plane (GND) via thermally enhanced connection.

FIGURE 1. TIMING DIAGRAM

Operation and Adaptive Shoot-Through Protection

Designed for high speed switching, the ISL6610, ISL6610A MOSFET driver controls both high-side and low-side N-Channel FETs from one externally provided PWM signal.

A rising transition on PWM initiates the turn-off of the lower MOSFET (see Figure 1). After a short propagation delay [t_{PDLL}], the lower gate begins to fall. Typical fall times [t_{FL}] are provided in the *Electrical Specifications*. Adaptive shoot-through circuitry monitors the LGATE voltage and turns on the upper gate following a short delay time [t_{PDHU}] after the LGATE voltage drops below $\sim 1V$. The upper gate drive then begins to rise [t_{RU}] and the upper MOSFET turns on.

A falling transition on PWM indicates the turn-off of the upper MOSFET and the turn-on of the lower MOSFET. A short propagation delay [t_{PDLU}] is encountered before the upper gate begins to fall [t_{FU}]. The adaptive shoot-through circuitry monitors the UGATE-PHASE voltage and turns on the lower MOSFET a short delay time, t_{PDHL} , after the upper MOSFET's gate voltage drops below $1V$. The lower gate then rises [t_{RL}], turning on the lower MOSFET. These methods prevent both the lower and upper MOSFETs from conducting simultaneously (shoot-through), while adapting the dead time to the gate charge characteristics of the MOSFETs being used.

This driver is optimized for voltage regulators with large step down ratio. The lower MOSFET is usually sized larger compared to the upper MOSFET because the lower MOSFET conducts for a longer time during a switching period. The lower gate driver is therefore sized much larger to meet this application requirement. The 0.4Ω on-resistance and 4A sink current capability enable the lower gate driver to

absorb the current injected into the lower gate through the drain-to-gate capacitor (C_{GD}) of the lower MOSFET and help prevent shoot through caused by the self turn-on of the lower MOSFET due to high dV/dt of the switching node.

Tri-State PWM Input

A unique feature of the ISL6610, ISL6610A is the adaptable tri-state PWM input. Once the PWM signal enters the shutdown window, either MOSFET previously conducting is turned off. If the PWM signal remains within the shutdown window for longer than 80ns of the previously conducting MOSFET, the output drivers are disabled and both MOSFET gates are pulled and held low. The shutdown state is removed when the PWM signal moves outside the shutdown window. The PWM rising and falling thresholds outlined in the *Electrical Specifications* determine when the lower and upper gates are enabled. During normal operation in a typical application, the PWM rise and fall times through the shutdown window should not exceed either output's turn-off propagation delay plus the MOSFET gate discharge time to $\sim 1V$. Abnormally long PWM signal transition times through the shutdown window will simply introduce additional dead time between turn off and turn on of the synchronous bridge's MOSFETs. For optimal performance, no more than 100pF parasitic capacitive load should be present on the PWM line of ISL6610, ISL6610A (assuming an Intersil PWM controller is used).

Bootstrap Considerations

This driver features an internal bootstrap diode. Simply adding an external capacitor across the BOOT and PHASE pins completes the bootstrap circuit. The ISL6610A's internal bootstrap resistor is designed to reduce the overcharging of

the bootstrap capacitor when exposed to excessively large negative voltage swing at the PHASE node. Typically, such large negative excursions occur in high current applications that use D²-PAK and D-PAK MOSFETs or excessive layout parasitic inductance. The following equation helps select a proper bootstrap capacitor size:

$$C_{\text{BOOT_CAP}} \geq \frac{Q_{\text{GATE}}}{\Delta V_{\text{BOOT_CAP}}} \quad (\text{EQ. 1})$$

$$Q_{\text{GATE}} = \frac{Q_{\text{G1}} \cdot \text{PVCC}}{V_{\text{GS1}}} \cdot N_{\text{Q1}}$$

where Q_{G1} is the amount of gate charge per upper MOSFET at V_{GS1} gate-source voltage and N_{Q1} is the number of control MOSFETs. The $\Delta V_{\text{BOOT_CAP}}$ term is defined as the allowable droop in the rail of the upper gate drive.

As an example, suppose two HAT2168 FETs are chosen as the upper MOSFETs. The gate charge, Q_{G} , from the data sheet is 12nC at 5V (V_{GS}) gate-source voltage. Then the Q_{GATE} is calculated to be 26.4nC at 5.5V PVCC level. We will assume a 100mV droop in drive voltage over the PWM cycle. We find that a bootstrap capacitance of at least 0.264 μF is required. The next larger standard value capacitance is 0.33 μF . A good quality ceramic capacitor is recommended.

FIGURE 2. BOOTSTRAP CAPACITANCE vs BOOT RIPPLE VOLTAGE

Power Dissipation

Package power dissipation is mainly a function of the switching frequency (F_{SW}), the output drive impedance, the external gate resistance, and the selected MOSFET's internal gate resistance and total gate charge. Calculating the power dissipation in the driver for a desired application is critical to ensure safe operation. Exceeding the maximum allowable power dissipation level will push the IC beyond the maximum recommended operating junction temperature of +125°C. The maximum allowable IC power dissipation for

the SO14 package is approximately 1W at room temperature, while the power dissipation capacity in the QFN packages, with an exposed heat escape pad, is around 2W. See Layout Considerations paragraph for thermal transfer improvement suggestions. When designing the driver into an application, it is recommended that the following calculation is used to ensure safe operation at the desired frequency for the selected MOSFETs. The total gate drive power losses due to the gate charge of MOSFETs and the driver's internal circuitry and their corresponding average driver current can be estimated with Equations 2 and 3, respectively,

$$P_{\text{Qg_TOT}} = 2 \cdot (P_{\text{Qg_Q1}} + P_{\text{Qg_Q2}}) + I_{\text{Q}} \cdot \text{VCC} \quad (\text{EQ. 2})$$

$$P_{\text{Qg_Q1}} = \frac{Q_{\text{G1}} \cdot \text{PVCC}^2}{V_{\text{GS1}}} \cdot F_{\text{SW}} \cdot N_{\text{Q1}}$$

$$P_{\text{Qg_Q2}} = \frac{Q_{\text{G2}} \cdot \text{PVCC}^2}{V_{\text{GS2}}} \cdot F_{\text{SW}} \cdot N_{\text{Q2}}$$

$$I_{\text{DR}} = 2 \cdot \left(\frac{Q_{\text{G1}} \cdot N_{\text{Q1}}}{V_{\text{GS1}}} + \frac{Q_{\text{G2}} \cdot N_{\text{Q2}}}{V_{\text{GS2}}} \right) \cdot F_{\text{SW}} + I_{\text{Q}} \quad (\text{EQ. 3})$$

where the gate charge (Q_{G1} and Q_{G2}) is defined at a particular gate to source voltage (V_{GS1} and V_{GS2}) in the corresponding MOSFET datasheet; I_{Q} is the driver's total quiescent current with no load at both drive outputs and can be negligible; N_{Q1} and N_{Q2} are number of upper and lower MOSFETs, respectively. The factor 2 is the number of active channels. The $I_{\text{Q}} \text{VCC}$ product is the quiescent power of the driver without capacitive load and is typically negligible.

The total gate drive power losses are dissipated among the resistive components along the transition path. The drive resistance dissipates a portion of the total gate drive power losses, the rest will be dissipated by the external gate resistors (R_{G1} and R_{G2} , should be a short to avoid interfering with the operation shoot-through protection circuitry) and the internal gate resistors (R_{G11} and R_{G12}) of MOSFETs. Figures 3 and 4 show the typical upper and lower gate drives turn-on transition path. The power dissipation on the driver can be roughly estimated as:

$$P_{\text{DR}} = 2 \cdot (P_{\text{DR_UP}} + P_{\text{DR_LOW}}) + I_{\text{Q}} \cdot \text{VCC} \quad (\text{EQ. 4})$$

$$P_{\text{DR_UP}} = \left(\frac{R_{\text{HI1}}}{R_{\text{HI1}} + R_{\text{EXT1}}} + \frac{R_{\text{LO1}}}{R_{\text{LO1}} + R_{\text{EXT1}}} \right) \cdot \frac{P_{\text{Qg_Q1}}}{2}$$

$$P_{\text{DR_LOW}} = \left(\frac{R_{\text{HI2}}}{R_{\text{HI2}} + R_{\text{EXT2}}} + \frac{R_{\text{LO2}}}{R_{\text{LO2}} + R_{\text{EXT2}}} \right) \cdot \frac{P_{\text{Qg_Q2}}}{2}$$

$$R_{\text{EXT2}} = R_{\text{G1}} + \frac{R_{\text{G11}}}{N_{\text{Q1}}} \quad R_{\text{EXT2}} = R_{\text{G2}} + \frac{R_{\text{G12}}}{N_{\text{Q2}}}$$

Application Information

MOSFET and Driver Selection

The parasitic inductances of the PCB and of the power devices' packaging (both upper and lower MOSFETs) can cause serious ringing, exceeding absolute maximum rating of the devices. The negative ringing at the edges of the PHASE node could increase the bootstrap capacitor voltage through the internal bootstrap diode, and in some cases, it may overstress the upper MOSFET driver. Careful layout, proper selection of MOSFETs and packaging, as well as the proper driver can go a long way toward minimizing such unwanted stress.

FIGURE 5. PHASE RESISTOR TO MINIMIZE SERIOUS NEGATIVE PHASE SPIKE

The selection of D²-PAK, or D-PAK packaged MOSFETs, is a much better match (for the reasons discussed) for the ISL6610A with a phase resistor, as shown in Figure 5. Low-

profile MOSFETs, such as Direct FETs and multi-SOURCE leads devices (SO-8, LPAK, PowerPAK), have low parasitic lead inductances and can be driven by either ISL6610 or ISL6610A (assuming proper layout design). The ISL6610, missing the 3Ω integrated BOOT resistor, typically yields slightly higher efficiency than the ISL6610A.

Layout Considerations

A good layout helps reduce the ringing on the switching node (PHASE) and significantly lower the stress applied to the output drives. The following advice is meant to lead to an optimized layout and performance:

- Keep decoupling loops (VCC-GND, PVCC-PGND and BOOT-PHASE) short and wide, at least 25 mils. Avoid using vias on decoupling components other than their ground terminals, which should be on a copper plane with at least two vias.
- Minimize trace inductance, especially on low-impedance lines. All power traces (UGATE, PHASE, LGATE, PGND, PVCC, VCC, GND) should be short and wide, at least 25 mils. Try to place power traces on a single layer, otherwise, two vias on interconnection are preferred where possible. For no connection (NC) pins on the QFN part, connect it to the adjacent net (LGATE2/PHASE2) can reduce trace inductance.
- Shorten all gate drive loops (UGATE-PHASE and LGATE-PGND) and route them closely spaced.
- Minimize the inductance of the PHASE node. Ideally, the source of the upper and the drain of the lower MOSFET should be as close as thermally allowable.
- Minimize the current loop of the output and input power trains. Short the source connection of the lower MOSFET to ground as close to the transistor pin as feasible. Input capacitors (especially ceramic decoupling) should be placed as close to the drain of upper and source of lower MOSFETs as possible.
- Avoid routing relatively high impedance nodes (such as PWM and ENABLE lines) close to high dV/dt UGATE and PHASE nodes.

In addition, connecting the thermal pad of the QFN package to the power ground through multiple vias, or placing a low noise copper plane (such as power ground) underneath the SOIC part is recommended. This is to improve heat dissipation and allow the part to achieve its full thermal potential.

Upper MOSFET Self Turn-On Effects At Startup

Should the driver have insufficient bias voltage applied, its outputs are floating. If the input bus is energized at a high dV/dt rate while the driver outputs are floating, due to the self-coupling via the internal C_{GD} of the MOSFET, the UGATE could momentarily rise up to a level greater than the threshold voltage of the MOSFET. This could potentially turn on the upper switch and result in damaging inrush energy.

Therefore, if such a situation (when input bus powered up before the bias of the controller and driver is ready) could conceivably be encountered, it is a common practice to place a resistor (R_{UGPH}) across the gate and source of the upper MOSFET to suppress the Miller coupling effect. The value of the resistor depends mainly on the input voltage's rate of rise, the C_{GD}/C_{GS} ratio, as well as the gate-source threshold of the upper MOSFET. A higher dV/dt , a lower C_{DS}/C_{GS} ratio, and a lower gate-source threshold upper FET will require a smaller resistor to diminish the effect of the internal capacitive coupling. For most applications, the integrated $20k\Omega$ typically sufficient, not affecting normal performance and efficiency.

The coupling effect can be roughly estimated with the following equations, which assume a fixed linear input ramp and neglect the clamping effect of the body diode of the upper drive and the bootstrap capacitor. Other parasitic components such as lead inductances and PCB capacitances are also not taken into account. These equations are provided for guidance purpose only. Therefore, the actual coupling effect should be examined using a very high impedance ($10M\Omega$ or greater) probe to ensure a safe design margin.

$$I_{GS_MILLER} = \frac{dV}{dt} \cdot R \cdot C_{r_{SS}} \left(1 - e^{\frac{-V_{DS}}{dt} \cdot R \cdot C_{i_{SS}}} \right) \quad (\text{EQ. 5})$$

$$R = R_{UGPH} + R_{GI} \quad C_{r_{SS}} = C_{GD} \quad C_{i_{SS}} = C_{GD} + C_{GS}$$
