## FEATURES

Input frequencies from $\mathbf{8 k H z}$ to $\mathbf{7 1 0} \mathbf{~ M H z}$
Output frequencies up to $810 \mathbf{~ M H z}$
Preset pin-programmable frequency translation ratios cover popular wireline and wireless frequency applications, including xDSL, T1/E1, BITS, SONET, and Ethernet.
Arbitrary frequency translation ratios via SPI port
On-chip VCO
Accepts a crystal resonator for holdover applications
Two single-ended (or one differential) reference input(s)
Two output clocks (independently programmable as LVDS, LVPECL, or CMOS)
SPI-compatible, 3-wire programming interface
Single supply (3.3 V)
Very low power: <450 mW (under most conditions)
Small package size ( $5 \mathrm{~mm} \times 5 \mathrm{~mm}$ )
Exceeds Telcordia GR-253 Category II OC-48 jitter generation, transfer, and tolerance specifications

## APPLICATIONS

Cost effective replacement of high frequency VCXO, OCXO, and SAW resonators
Extremely flexible frequency translation for SONET/SDH,
Gb Ethernet, Fibre Channel, DRFI/DOCSIS, and PON/EPON/GPON
Wireless infrastructure
Test and measurement (including handheld devices)

## GENERAL DESCRIPTION

The AD9553 is a phase-locked loop (PLL) based clock translator designed to address the needs of passive optical networks (PON) and base stations. The device employs an integer-N PLL to accommodate the applicable frequency translation requirements. The user supplies up to two single-ended input reference signals or one differential input reference signal via the REFA and REFB inputs. The device supports holdover applications by allowing the user to connect a 25 MHz crystal resonator to the XTAL input.
The AD9553 is pin programmable, providing a matrix of standard input/output frequency translations from a list of 15 possible input frequencies to a list of 51 possible output frequency pairs (OUT1 and OUT2). The device also has a 3-wire SPI interface, enabling the user to program custom input-to-output frequency translations.

The AD9553 output is compatible with LVPECL, LVDS, or single-ended CMOS logic levels, although the AD9553 is implemented in a strictly CMOS process.
The AD9553 operates over the extended industrial temperature range of $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$.

## REVISION HISTORY

4/10—Revision 0: Initial Version

## SPECIFICATIONS

## POWER CONSUMPTION

Table 1.

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| TOTAL CURRENT |  | 162 | 185 | mA | Tested with both output channels active at maximum output frequency. LVPECL and LVDS outputs use a $100 \Omega$ termination between both pins of the output driver. |
| VDD CURRENT BY PIN |  |  |  |  | Tested with both output channels active at maximum output frequency. LVPECL and LVDS outputs use a $100 \Omega$ termination between both pins of the output driver. |
| Pin 18 |  | 93 | 106 | mA |  |
| Pin 21 |  |  |  |  |  |
| LVDS Configured Output |  | 35 | 41 | mA |  |
| LVPECL Configured Output |  | 36 | 42 | mA |  |
| CMOS Configured Output |  | 29 | 34 | mA |  |
| Pin 28 |  |  |  |  |  |
| LVDS Configured Output |  | 35 | 41 | mA |  |
| LVPECL Configured Output |  | 36 | 42 | mA |  |
| CMOS Configured Output |  | 29 | 34 | mA |  |

## LOGIC INPUT PINS

Table 2.

| Parameter | Min $\quad$ Typ $\quad$ Max | Unit | Test Conditions/Comments |  |
| :--- | :--- | :--- | :--- | :--- |
| INPUT CHARACTERISTICS ${ }^{1}$ |  |  |  |  |
| Logic 1 Voltage, $\mathrm{V}_{\mathrm{IH}}$ | 1.02 |  | V | For the CMOS inputs, a static Logic 1 results <br> from either a pull-up resistor or no connection. |
| Logic 0 Voltage, $\mathrm{V}_{\mathrm{IL}}$ |  | 0.64 | V |  |
| Logic 1 Current, $\mathrm{I}_{\mathrm{IH}}$ |  | 3 | $\mu \mathrm{~A}$ |  |
| Logic 0 Current, $\mathrm{I}_{\mathrm{IL}}$ |  | 17 | $\mu \mathrm{~A}$ |  |

${ }^{1}$ The $\mathrm{A}[3: 0]$ and $\mathrm{Y}[5: 0]$ pins have $100 \mathrm{k} \Omega$ internal pull-up resistors. The $\mathrm{OM}[2: 0]$ pins have $40 \mathrm{k} \Omega$ pull-up resistors when the device is not in SPI mode.

## LOGIC OUTPUT PINS

Table 3.

| Parameter | Min $\quad$ Typ | Max | Unit | Test Conditions/Comments |
| :--- | :--- | :--- | :--- | :--- |
| OUTPUT CHARACTERISTICS |  |  |  |  |
| Output Voltage High, $\mathrm{V}_{\mathrm{OH}}$ | 2.7 |  | V | Tested at 1 mA load current |
| Output Voltage Low, $\mathrm{V}_{\mathrm{oL}}$ |  | 0.19 | V | Tested at 1 mA load current |

## AD9553

## RESET PIN

Table 4.

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| INPUT CHARACTERISTICS ${ }^{1}$ |  |  |  |  |  |
| Input Voltage High, $\mathrm{V}_{\mathrm{H}}$ | 1.96 |  |  | V |  |
| Input Voltage Low, $\mathrm{V}_{\text {IL }}$ |  |  | 0.85 | V |  |
| Input Current High, $\mathrm{I}_{\mathrm{NH}}$ |  | 0.3 | 12.5 | $\mu \mathrm{A}$ |  |
| Input Current Low, lint |  | 31 | 43 | $\mu \mathrm{A}$ |  |
| MINIMUM PULSE WIDTH LOW | 150 |  |  | $\mu \mathrm{s}$ | Tested with an active source driving the $\overline{\text { RESET }}$ pin. |

## REFERENCE CLOCK INPUT CHARACTERISTICS

Table 5.

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| DIFFERENTIAL INPUT |  |  |  |  |  |
| Input Frequency Range | 0.008 |  | 250 | MHz |  |
|  |  |  | 710 | MHz | Assumes minimum LVDS input level and requires bypassing of the $/ 5$ divider and $2 \times$ multiplier. |
| Common-Mode Internally Generated Input Voltage | 613 | 692 | 769 | mV | Use ac coupling to preserve the internal dc bias of the differential input. |
| Differential Input Voltage Sensitivity | 250 |  |  | mV p-p | Capacitive coupling required; can accommodate singleended input by ac grounding unused input; the instantaneous voltage on either pin must not exceed the 3.3 V dc supply rails. |
| Differential Input Resistance |  | 5 |  | k $\Omega$ |  |
| Differential Input Capacitance |  | 3 |  | pF |  |
| Duty Cycle |  |  |  |  | Pulse width high and pulse width low establish the bounds for duty cycle. |
| Pulse Width Low | 1.6 |  |  | ns | Up to 250 MHz . |
| Pulse Width High | 1.6 |  |  | ns | Up to 250 MHz . |
| Pulse Width Low | 0.64 |  |  | ns | Beyond 250 MHz , up to 710 MHz . |
| Pulse Width High | 0.64 |  |  | ns | Beyond 250 MHz , up to 710 MHz . |
| CMOS SINGLE-ENDED INPUT |  |  |  |  |  |
| Input Frequency Range | 0.008 |  | 200 | MHz |  |
| Input High Voltage ${ }^{1}$ | 1.05 |  |  | V |  |
| Input Low Voltage ${ }^{1}$ |  |  | 0.98 | V |  |
| Input High Current |  | 0.04 |  | $\mu \mathrm{A}$ |  |
| Input Low Current |  | 0.03 |  | $\mu \mathrm{A}$ |  |
| Input Capacitance |  | 3 |  | pF |  |
| Duty Cycle |  |  |  |  | Pulse width high and pulse width low establish the bounds for duty cycle. |
| Pulse Width Low | 2 |  |  | ns |  |
| Pulse Width High | 2 |  |  | ns |  |
| $2 \times$ FREQUENCY MULTIPLIER |  |  | 125 | MHz | To avoid excessive reference spurs, the $2 \times$ multiplier requires $48 \%$ to $52 \%$ duty cycle. Reference clock input frequencies greater than 125 MHz require the use of the /5 divider. |

${ }^{1}$ The single-ended CMOS input is 3.3 V compatible. In the case of ac-coupling, the user must bias the input at 1.0 V dc.

## VCO CHARACTERISTICS

Table 6.

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| FREQUENCY RANGE | 3350 |  | 4050 | MHz |  |
| VCO GAIN |  | 45 |  | MHz/V |  |
| VCO TRACKING RANGE | $\pm 300$ |  |  | ppm |  |
| VCO CALIBRATION TIME |  |  |  |  | As measured from completion of the VCO calibration command (the rising edge of $\overline{C S}$ (Pin 12)) until the rising edge of LOCKED (Pin 20). |
| Low BW Setting ( 170 Hz ) |  |  |  |  | Applies for $\mathrm{A}[3: 0]=0001$ to 1100 or for $\mathrm{A}[3: 0]=1111$. |
| 13.3 kHz PFD Frequency |  | 214 |  | ms |  |
| 16 kHz PFD Frequency |  | 176 |  | ms |  |
| High BW Setting ( 75 kHz ) |  |  |  |  | Applies for $\mathrm{A}[3: 0]=1101$ to 1110. |
| 2.64 MHz PFD Frequency |  | 1.46 |  | ms |  |
| 4.86 MHz PFD Frequency |  | 0.80 |  | ms |  |
| PLL LOCK TIME |  |  |  |  | Using the pin selected frequency settings. Lock time is from the rising edge of the RESET pin to the rising edge of the LOCKED pin. |
| Low BW Setting ( 170 Hz ) |  |  |  |  | Applies for $\mathrm{A}[3: 0]=0001$ to 1100 or for $\mathrm{A}[3: 0]=1111$. |
| 13.3 kHz PFD Frequency |  | 214 |  | ms |  |
| 16 kHz PFD Frequency |  | 176 |  | ms |  |
| High BW Setting ( 75 kHz ) |  |  |  |  | Applies for $\mathrm{A}[3: 0]=1101$ to 1110. |
| 2.64 MHz PFD Frequency |  | 1.50 |  | ms |  |
| 4.86 MHz PFD Frequency |  | 0.89 |  | ms |  |

## CRYSTAL INPUT CHARACTERISTICS

Table 7.

| Parameter | Min | Typ | Max | Unit |
| :--- | :--- | :--- | :--- | :--- |
| CRYSTAL FREQUENCY <br> Range | 10 | 25 | 52 | Test Conditions/Comments |
| Tolerance | 20 | ppm |  |  |
| CRYSTAL MOTIONAL RESISTANCE |  | 100 | $\Omega$ | When using the pin selected frequency settings, the device <br> requires a 25 MHz crystal to support holdover functionality. |
| CRYSTAL LOAD CAPACITANCE |  | 10 | pF | Using a crystal with a specified load capacitance other than 10 pF <br> $(8 \mathrm{pF}$ to 24 pF) is possible, but necessitates using the SPI port. |

## AD9553

## OUTPUT CHARACTERISTICS

Table 8.

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| LVPECL MODE |  |  |  |  |  |
| Differential Output Voltage Swing | 690 | 800 | 890 | mV | Output driver static (for dynamic performance, see Figure 13). |
| Common-Mode Output Voltage | VDD-1.66 | VDD-1.34 | VDD-1.01 | v | Output driver static. |
| Frequency Range | 0 |  | 810 | MHz |  |
| Duty Cycle | 40 |  | 60 | \% | Up to 805 MHz output frequency. |
| Rise/Fall Time ${ }^{1}$ (20\% to 80\%) |  | 255 | 305 | ps | $100 \Omega$ termination between the output driver pins. |
| LVDS MODE |  |  |  |  |  |
| Differential Output Voltage Swing |  |  |  |  | Output driver static (for dynamic performance, see Figure 13). |
| Balanced, V ${ }_{\text {od }}$ | 297 |  | 398 | mV | Voltage swing between output pins; output driver static. |
| Unbalanced, $\mathrm{V}_{\text {Oo }}$ |  |  | 8.3 | mV | Absolute difference between voltage swing of normal pin and inverted pin; output driver static. |
| Offset Voltage |  |  |  |  |  |
| Common Mode, Vos | 1.17 |  | 1.35 | V | Output driver static. |
| Common-Mode Difference, $\Delta V_{0}$ |  |  | 7.3 | mV | Voltage difference between output pins; output driver static. |
| Short-Circuit Output Current |  | 17 | 24 | mA |  |
| Frequency Range | 0 |  | 810 | MHz |  |
| Duty Cycle | 40 |  | 60 | \% | Up to 805 MHz output frequency. |
| Rise/Fall Time' ${ }^{1}$ (20\% to 80\%) |  | 285 | 355 | ps | $100 \Omega$ termination between the output driver pins. |
| CMOS MODE |  |  |  |  |  |
| Output Voltage High, $\mathrm{V}_{\text {OH }}$ |  |  |  |  | Output driver static; standard drive strength setting. |
| $\mathrm{l}_{\mathrm{OH}}=10 \mathrm{~mA}$ | 2.8 |  |  | V |  |
| $\mathrm{l}_{\text {OH }}=1 \mathrm{~mA}$ | 2.8 |  |  | V |  |
| Output Voltage Low, Voı |  |  |  |  | Output driver static; standard drive strength setting. |
| $\mathrm{loL}=10 \mathrm{~mA}$ |  |  | 0.5 | V |  |
| $\mathrm{l}_{\mathrm{oL}}=1 \mathrm{~mA}$ |  |  | 0.3 | V |  |
| Frequency Range | 0 |  | 200 | MHz | 3.3 V CMOS; standard drive strength setting. Output toggle rates in excess of the maximum are possible, but with reduced amplitude (see Figure 12). |
| Duty Cycle | 45 |  | 55 | \% | At maximum output frequency. |
| Rise/Fall Time ${ }^{1}$ (20\% to 80\%) |  | 500 | 745 | ps | 3.3 V CMOS; standard drive strength setting; 10 pF load. |

${ }^{1}$ The listed values are for the slower edge (rise or fall).

## JITTER CHARACTERISTICS

Table 9.

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| JITTER GENERATION |  |  |  |  |  |
| 12 kHz to 20 MHz |  |  |  |  |  |
| LVPECL Output |  | 1.31 |  | ps rms | Input $=122.88 \mathrm{MHz}$, output $=155.52 \mathrm{MHz}$. |
| LVDS Output |  | 1.32 |  | ps rms | Input $=122.88 \mathrm{MHz}$, output $=155.52 \mathrm{MHz}$. |
| CMOS Output |  | 1.24 |  | ps rms | Input $=122.88 \mathrm{MHz}$, output $=155.52 \mathrm{MHz}$. |
| LVPECL Output |  | 1.28 |  | ps rms | Input $=19.44 \mathrm{MHz}$, output $=245.76 \mathrm{MHz}$. |
| LVDS Output |  | 1.29 |  | ps rms | Input $=19.44 \mathrm{MHz}$, output $=245.76 \mathrm{MHz}$. |
| CMOS Output |  | 1.26 |  | ps rms | Input $=19.44 \mathrm{MHz}$, output $=245.76 \mathrm{MHz}$. See Figure 12 regarding CMOS toggle rates above 250 MHz . |
| 50 kHz to 80 MHz |  |  |  |  | Input $=122.88 \mathrm{MHz}$, output $=155.52 \mathrm{MHz}$. |
| LVPECL Output |  | 0.44 |  | ps rms | Input $=122.88 \mathrm{MHz}$, output $=155.52 \mathrm{MHz}$. |
| LVDS Output |  | 0.45 |  | ps rms | Input $=122.88 \mathrm{MHz}$, output $=155.52 \mathrm{MHz}$. |
| CMOS Output |  | 0.39 |  | ps rms | Input $=122.88 \mathrm{MHz}$, output $=155.52 \mathrm{MHz}$. |
| LVPECL Output |  | 0.75 |  | ps rms | Input $=19.44 \mathrm{MHz}$, output $=245.76 \mathrm{MHz}$. |
| LVDS Output |  | 0.76 |  | ps rms | Input $=19.44 \mathrm{MHz}$, output $=245.76 \mathrm{MHz}$. |
| CMOS Output |  | 0.44 |  | ps rms | Input $=19.44 \mathrm{MHz}$, output $=245.76 \mathrm{MHz}$. See Figure 12 regarding CMOS toggle rates above 250 MHz . |
| JITTER TRANSFER BANDWIDTH |  |  |  |  | See the Typical Performance Characteristics section. |
| Low BW Setting |  | 170 |  | Hz | Applies to all input frequency pin programming configurations that use 170 Hz loop bandwidth per Table 17. |
| High BW Setting |  | 75 |  | kHz | Applies to all input frequency pin programming configurations that use 75 kHz loop bandwidth per Table 17. |
| JITTER TRANSFER PEAKING |  |  |  |  | See the Typical Performance Characteristics section |
| Low BW Setting |  | 1.3 |  | dB | Applies to all input frequency pin programming configurations that use 170 Hz loop bandwidth per Table 17. |
| High BW Setting |  | 0.08 |  | dB | Applies to all input frequency pin programming configurations that use 75 kHz loop bandwidth per Table 17. |

## AD9553

## SERIAL CONTROL PORT

Table 10.

| Parameter | Min | Typ | Max | Unit | Test Conditions/Comments |
| :---: | :---: | :---: | :---: | :---: | :---: |
| $\overline{\overline{C S}}$ |  |  |  |  |  |
| Input Logic 1 Voltage | 1.6 |  |  | V |  |
| Input Logic 0 Voltage |  |  | 0.5 | V |  |
| Input Logic 1 Current |  |  | 0.03 | $\mu \mathrm{A}$ |  |
| Input Logic 0 Current |  | 2 |  | $\mu \mathrm{A}$ |  |
| Input Capacitance |  | 2 |  | pF |  |
| SCLK |  |  |  |  |  |
| Input Logic 1 Voltage | 1.6 |  |  | V |  |
| Input Logic 0 Voltage |  |  | 0.5 | V |  |
| Input Logic 1 Current |  | 2 |  | $\mu \mathrm{A}$ |  |
| Input Logic 0 Current |  |  | 0.03 | $\mu \mathrm{A}$ |  |
| Input Capacitance |  | 2 |  | pF |  |
| SDIO |  |  |  |  |  |
| Input |  |  |  |  |  |
| Input Logic 1 Voltage | 1.6 |  |  | V |  |
| Input Logic 0 Voltage |  |  | 0.5 | V |  |
| Input Logic 1 Current |  | 1 |  | $\mu \mathrm{A}$ |  |
| Input Logic 0 Current |  | 1 |  | $\mu \mathrm{A}$ |  |
| Input Capacitance |  | 2 |  | pF |  |
| Output |  |  |  |  |  |
| Output Logic 1 Voltage | 2.8 |  |  | V | 1 mA load current |
| Output Logic 0 Voltage |  |  | 0.3 | V | 1 mA load current |

## SERIAL CONTROL PORT TIMING

Table 11.

| Parameter | Limit | Unit |
| :---: | :---: | :---: |
| SCLK |  |  |
| Clock Rate, 1/tclk | 50 | MHz max |
| Pulse Width High, thigh | 3 | ns min |
| Pulse Width Low, tıow | 3 | ns min |
| SDIO to SCLK Setup, tos | 4 | ns min |
| SCLK to SDIO Hold, $\mathrm{toH}^{\text {d }}$ | 0 | $n s$ min |
| SCLK to Valid SDIO, tov | 13 | ns max |
| $\overline{\mathrm{CS}}$ to SCLK Setup (ts) and Hold ( $\mathrm{tr}_{\text {) }}$ | 0 | $n \mathrm{~ns}$ min |
| $\overline{\mathrm{CS}}$ Minimum Pulse Width High | 6.4 | $n \mathrm{nsmin}$ |

## ABSOLUTE MAXIMUM RATINGS

Table 12.

| Parameter | Rating |
| :--- | :--- |
| Supply Voltage (VDD) | 3.6 V |
| Maximum Digital Input Voltage | -0.5 V to VDD +0.5 V |
| Storage Temperature Range | $-65^{\circ} \mathrm{C}$ to $+150^{\circ} \mathrm{C}$ |
| Operating Temperature Range | $-40^{\circ} \mathrm{C}$ to $+85^{\circ} \mathrm{C}$ |
| Lead Temperature (Soldering, 10 sec ) | $300^{\circ} \mathrm{C}$ |
| Junction Temperature | $150^{\circ} \mathrm{C}$ |

Stresses above those listed under Absolute Maximum Ratings may cause permanent damage to the device. This is a stress rating only; functional operation of the device at these or any other conditions above those indicated in the operational section of this specification is not implied. Exposure to absolute maximum rating conditions for extended periods may affect device reliability.

## ESD CAUTION

ESD (electrostatic discharge) sensitive device. Charged devices and circuit boards can discharge without detection. Although this product features patented or proprietary protection circuitry, damage may occur on devices subjected to high energy ESD. Therefore, proper ESD precautions should be taken to avoid performance degradation or loss of functionality.

## AD9553

## PIN CONFIGURATION AND FUNCTION DESCRIPTIONS

Figure 2. Pin Configuration
Table 13. Pin Function Descriptions

| Pin No. | Mnemonic | Type ${ }^{1}$ | Description |
| :---: | :---: | :---: | :---: |
| $\begin{aligned} & 29,30,31, \\ & 32,1,2 \end{aligned}$ | $\begin{aligned} & \mathrm{Y} 0, \mathrm{Y} 1, \mathrm{Y} 2, \mathrm{Y} 3, \\ & \mathrm{Y} 4, \mathrm{Y} 5 \end{aligned}$ | I | Control Pins. These pins select one of 51 preset output frequency combinations for OUT1 and OUT2. Note that when all six control pins are Logic $0, \mathrm{SPI}$ programming is active. |
| 3, 4, 5, 6 | A0, A1, A2, A3 | I | Control Pins. These pins select one of 15 preset input reference frequencies. Note that when all four control pins are Logic 0, SPI programming is active. |
| 7 | REFA | I | Reference Clock Input. Connect this pin to a single-ended active clock input signal. Alternatively, this pin is the noninverted part of a differential clock input signal. |
| 8 | REFB/ $\overline{\text { REFA }}$ | I | Reference Clock Input. Connect this pin to a single-ended active clock input signal. Alternatively, this pin is the inverted part of a differential clock input signal. |
| 9,10 | XTAL | I | Crystal Resonator Input. Connect a crystal resonator across these pins. When using the preset input/output frequencies via the $\mathrm{Y}[5: 0]$ and $\mathrm{A}[3: 0]$ pins, the crystal must have a resonant frequency of 25 MHz with a specified load capacitance of 10 pF . |
| 11 | SEL REFB | I | Control Pin. This pin allows manual selection of REFA (Logic 0 ) or REFB (Logic 1 ) as the active reference assuming that the desired reference signal is present. Note that this pin is nonfunctional when Register 0x29[5] = 1 . |
| 12 | OM2/CS | 1 | Digital Input. When the device is not in SPI mode, this pin is an output mode control pin (OM2) with an internal $40 \mathrm{k} \Omega$ pull-up resistor. The OM2 pin, in conjunction with the OM0 and OM1 pins, allows the user to select 1 -of-8 output configurations (see Table 21). In SPI mode, this pin is an active low chip select $(\overline{\mathrm{CS}})$ with no internal pull-up resistor. |
| 13 | OM1/SCLK | I | Digital Input. When the device is not in SPI mode, this pin is an output mode control pin (OM1) with an internal $40 \mathrm{k} \Omega$ pull-up resistor. The OM1 pin, in conjunction with the OM0 and OM2 pins, allows the user to select 1-of-8 output configurations (see Table 21). In SPI mode, this pin is the serial data clock (SCLK) with no internal pull-up resistor. |
| 14 | OMO/SDIO | 1/O | Digital Input/Output. When the device is not in SPI mode, this pin is an input only and functions as an output mode control pin (OMO) with an internal $40 \mathrm{k} \Omega$ pull-up resistor. The OM0 pin, in conjunction with the OM1 and OM2 pins, allows the user to select 1-of-8 output configurations (see Table 21). In SPI mode, this pin is the serial data input/output (SDIO) with no internal pull-up resistor. |
| 15 | $\overline{\text { RESET }}$ | I | Digital Input, Active Low with a $100 \mathrm{k} \Omega$ Internal Pull-Up Resistor. Resets the internal logic to default states (see the Automatic Power-On Reset section). |
| 16 | FILTER | I/O | Loop Filter Node for the PLL. Connect external loop filter components (see Figure 22) from this pin to Pin 17 (LDO). |
| 17, 19 | LDO | P/O | LDO Decoupling Pins. Connect a $0.47 \mu \mathrm{~F}$ decoupling capacitor from each of these pins to ground. |
| 18, 21, 28 | VDD | P | Power Supply Connection: 3.3 V Analog Supply. |
| 20 | LOCKED | 0 | Active High Locked Status Indicator for the PLL. |
| 26, 22 | $\overline{\text { OUT1, OUT2 }}$ | 0 | Complementary Square Wave Clocking Outputs. |
| 27, 23 | OUT1, OUT2 | 0 | Square Wave Clocking Outputs. |
| 24, 25 | GND | P | Ground. |
| EP | Exposed die pad |  | The exposed die pad must be connected to GND. |

## PRESET FREQUENCIES

The frequency selection pins (A[3:0] and $\mathrm{Y}[5: 0]$ ) allow the user to hardwire the device for preset input and output frequencies based on the pin logic states (see Figure 20). The pins decode ground or open connections as Logic 0 or Logic 1, respectively.
In order to have access to the device control registers via the SPI port, the user must select $\mathrm{Y}[5: 0]=000000$ and/or $\mathrm{A}[3: 0]=0000$. Doing so causes Pin 12 through Pin 14 to function as SPI port control pins instead of output mode control pins (see the Output Driver Mode Control section). Note that after selecting SPI mode, the user must write a Logic 1 to Bit 0 of Register 0x32 and Register 0x34 to enable the registers as the source of the OUT1 and OUT2 mode control bits (see Figure 23 and the Output Driver Mode Control section).
The A[3:0] pins allow the user to select one of fifteen input reference frequencies as shown in Table 14. The device sets the appropriate divide-by- $5\left(/ 5_{\mathrm{A}}, / 5_{\mathrm{B}}\right)$, multiply-by- $2\left(\times 2_{\mathrm{A}}, \times 2_{\mathrm{B}}\right)$, and input divider $\left(\mathrm{R}_{\mathrm{A}}, \mathrm{R}_{\mathrm{B}}, \mathrm{R}_{\mathrm{xo}}\right)$ values based on the logic levels applied to the $\mathrm{A}[3: 0]$ pins.

The same settings apply to both the REFA and REFB input paths. Furthermore, the $/ 5, \times 2$, and R values cause the PLL input frequency to be either 16 kHz or $40 / 3 \mathrm{kHz}$. The exceptions are $\mathrm{A}[3: 0]=1101$ and 1110 , which yield a PLL input frequency of $155.52 / 59 \mathrm{MHz}$ and 4.86 MHz , respectively. Note that the XTAL input is not available for holdover functionality in the $\mathrm{A}[3: 0]=1101$ and 1110 configurations, thus the undefined Rxo value.
The Y [5:0] pins allow the user to select one of 51 output frequency combinations (fout1 and fout2) per Table 15. The device sets the appropriate $P_{0}, P_{1}$, and $P_{2}$ settings based on the logic levels applied to the $\mathrm{Y}[5: 0]$ pins. Note, however, that selections 101101 through 110010 require $\mathrm{A}[3: 0]=1101$ and selection 110011 requires $\mathrm{A}[3: 0]=1110$.

The value ( N ) of the PLL feedback divider and the control setting for the charge pump current (CP) depend on a combination of both the $\mathrm{A}[3: 0$ ] and $\mathrm{Y}[5: 0]$ pin settings as shown in Table 16.

## DEVICE CONTROL MODES

The AD9553 provides two modes of control: pin control and register control. Pin control, via the frequency selection pins (A [3:0] and Y[5:0]) as described in the Preset Frequencies section, is the simplest. Typically, pin control is for applications requiring only a single set of operating parameters (assuming that one of the options available via the frequency selection pins provides the parameters that satisfy the application requirements). Register control is typically for applications that require the flexibility to program different operating parameters
from time to time, or for applications that require parameters not available with any of the pin control options. The block diagram (see Figure 19) shows how the SPI and pin control modes interact.
The SPI/OM[2:0] label in Figure 19 refers to Pin 12, Pin 13 , and Pin 14 of the AD9553. Furthermore, the SPI mode signal is Logic 1 when $\mathrm{A}[3: 0]=0000$ and/or $\mathrm{Y}[5: 0]=000000$; otherwise, it is Logic 0 .

Figure 19. Control Mode Diagram

The SPI/OM[2:0] pins serve double duty (as either SPI pins or output mode control pins). A mux (controlled by the SPI mode signal) selects whether the three signals associated with the SPI/OM[2:0] pins connect to the output mode control decoder or to the SPI controller. Note that the SPI mode signal originates from the frequency selection pins decoder.
To enable communication with the SPI controller (SPI mode), the user must apply the appropriate logic pattern to the frequency selection pins (A[3:0] = 0000 and/or $\mathrm{Y}[5: 0]=000000)$. Note that as long as the frequency selection pins are set to invoke SPI mode, the user cannot establish output mode control via the output mode control decoder. Conversely, when the frequency selection pins are set to anything other than SPI mode, the user cannot communicate with the device via the SPI controller.

In Figure 19, note that some of the functions internal to the AD9553 are controlled by function bits that originate either from the two pin decoders or from within the register map. Specifically, each function receives its function bits from a function mux; and each function mux, in turn, receives its control signal from a single enable SPI control bit in the register map.
Be aware that the default values within the register map are such that all enable SPI control bits are Logic 0 . Thus, the default state of the device is such that each function mux selects the pin decoders (not the register map) as the source for all control functions.

In order to switch a function mux so that it selects function bits from the register map, the user must first set the frequency selection pins to SPI mode. Then, write a Logic 1 to the appropriate enable SPI control bit in the register map. Be aware that the function mux routes the function bits in the register map
to the selected function the instant that the enable SPI control bit becomes Logic 1 . Thus, it is a good idea to program the function bits to the desired state prior to writing Logic 1 to the corresponding enable SPI control bit.

Although the SPI and pin control modes are functionally independent, it is possible to mix the control modes. For example, suppose that pin control satisfies all of the requirements for an application except for the value of the $\mathrm{P}_{2}$ divider (which is associated with OUT2). The user could do the following:

- Activate SPI mode via the frequency selection pins.
- Program the desired $P_{0}, P_{1}$, and $P_{2}$ values in the register map (Register 0x15 to Register 0x18).
- Set the enable SPI control bit for the output dividers (Register 0x14[2] = 1).
- Calibrate the VCO by enabling SPI control of VCO calibration (Register $0 \times 0 \mathrm{E}[2]=1$ ), then issue a calibrate command (Register $0 \mathrm{x} 0 \mathrm{E}[7]=1$ ). Be sure to program the N divider, R dividers, $/ 5$ dividers, and $\times 2$ multipliers to the values defined by the $\mathrm{A}[3: 0]$ and $\mathrm{Y}[5: 0$ ] pin settings prior to calibrating the VCO.
- Restore the original settings to the frequency selection pins to invoke the desired frequency selection.

In this way, the function muxes that control $P_{0}, P_{1}$, and $P_{2}$ select the appropriate register bits as the source for controlling the dividers, while all the other function muxes select the pin decoders as the source for controlling the other functions. Note that the dividers remain under register control until the user activates SPI mode and writes Register 0x14[2] $=0$, thereby causing the function mux to use the frequency selection pins decoder as the source for controlling the dividers, instead of the register map.

## THEORY OF OPERATION

## GENERAL DESCRIPTION

The AD9553 can receive up to two input reference clocks, REFA and REFB. Both input clock paths include an optional divide-by- 5 (/5) prescaler, an optional $2 \times$ frequency multiplier, and a 14-bit programmable divider. Alternatively, the user can program the device to operate with one differential input clock (instead of two single-ended input clocks) via the serial I/O port. In the differential operating mode, the REFB path is inactive.
The AD9553 also has a dedicated XTAL input for direct connection of an optional 25 MHz crystal resonator. This allows for a backup clock signal useful for holdover operation in case both input references fail. The XTAL clock path includes a fixed $2 \times$ frequency multiplier and a 14 -bit programmable divider.
The AD9553 includes a switchover control block that automatically handles switching from REFA to REFB (or vice versa) in the event of a reference failure. If both REFA and REFB fail, however, then the switchover control block automatically enters holdover mode by selecting the XTAL clock signal (assuming the presence of a crystal resonator at the XTAL input).

Generally, the clock signals that appear at the input to the clock multiplexer (see Figure 20) all operate at the same frequency. Thus, the frequency at the input to the PLL (FPFD in Figure 20) is the same regardless of the signal selected by the clock multiplexer. The PLL converts FPFD to a frequency within the operating range of the VCO $(3.35 \mathrm{GHz}$ to 4.05 GHz$)$ based on the value of the feedback divider $(\mathrm{N})$. The VCO prescaler $\left(\mathrm{P}_{0}\right)$ reduces the VCO output frequency by a factor of either 5 or 6 ,
resulting in an intermediate frequency in the range of 558 MHz to 810 MHz . The 10 -bit $\mathrm{P}_{1}$ and $\mathrm{P}_{2}$ dividers can further reduce the $P_{0}$ output frequency to yield the final output clock frequencies at OUT1 and OUT2, respectively.

Thus, the frequency translation ratio from the reference input to the output depends on the selection of the $/ 5$ prescalers; the $2 \times$ frequency multipliers; the values of the three R dividers; the N divider; and the $\mathrm{P}_{0}, \mathrm{P}_{1}$, and $\mathrm{P}_{2}$ dividers. The user can set all of these parameters automatically by using the preconfigured divider settings available via the $\mathrm{A}[3: 0]$ and $\mathrm{Y}[5: 0]$ pins (see the Preset Frequencies section). Alternatively, the user can custom program these parameters via the serial I/O port (see the Serial Control Port and Register Map sections), allowing the device to accommodate custom frequency translation ratios.

## DESCRIPTION OF FUNCTIONAL BLOCKS

## Reference Inputs

The default configuration of the AD9553 provides up to two single-ended input clock receivers, REFA and REFB, which are high impedance CMOS inputs. In applications that require redundant reference clocks with switchover capability, REFA is the primary reference and REFB the secondary reference. Alternatively, the user can configure the input (via the serial I/O port) as a single differential receiver. In this case, the REFB input functions as $\overline{\text { REFA }}$ (the complementary input of REFA). Note that in this configuration the device operates with only one reference input clock, eliminating the need for switchover functionality.

## AD9553

## XTAL Input

The AD9553 accepts an optional 25 MHz crystal resonator connected across the XTAL pins. Unless otherwise programmed, the device expects the crystal to have a specified load capacitance of 10 pF (default). The AD9553 provides the necessary load capacitance internally. The internal load capacitance consists of a fixed component of 8 pF and a variable (programmable) component of 0 pF to 15.75 pF .
After applying power to the AD9553 (or after a device reset), the programmable component defaults to 2 pF . This establishes the default load capacitance of 10 pF ( 8 pF fixed plus 2 pF programmable).

To accommodate crystals with a specified load capacitance other than 10 pF ( 8 pF to 23.75 pF ), the user can adjust the programmable capacitance in 0.25 pF increments via Register $0 \times 1 \mathrm{~B}$ [5:0]. Note that when the user sets Register 0x1B[7] to 0 (enabling SPI control of the XTAL tuning capacitors), the variable capacitance changes from 2 pF (its default power-up value) to 15.75 pF due to the default value of Register $0 \times 1 \mathrm{~B}[5: 0]$. This causes the crystal load capacitance to be 23.75 pF until the user overwrites the default contents of Register $0 \times 1 \mathrm{~B}$ [5:0].

A noncomprehensive, alphabetical list of crystal manufacturers includes the following:

- AVX/Kyocera
- ECS
- Epson Toyocom
- Fox Electronics
- NDK
- Siward

Although these crystals meet the load capacitance and motional resistance requirements of the AD9553 according to their data sheets, Analog Devices, Inc., does not guarantee their operation with the AD9553, nor does Analog Devices endorse one supplier of crystals over another.

## Input Frequency Prescalers $\left(/ 5_{A} / 5_{B}\right)$

The $/ 5$ prescalers provide the option to reduce the input reference frequency by a factor of five. Note that the prescalers physically precede the $2 \times$ frequency multipliers. This allows the prescalers to bring a high frequency reference clock down to a frequency that is within the range of the $2 \times$ frequency multipliers.

## Input $\mathbf{2 \times}$ Frequency Multipliers ( $\mathbf{x} \mathbf{2}_{A}, \times \mathbf{2}_{B}$ )

The $2 \times$ frequency multipliers provide the option to double the frequency at their input. This allows the user to take advantage of a higher frequency at the input to the PLL (FPFD), which allows for greater separation between the frequency generated by the PLL and the modulation spur associated with FPFD. However, increased reference spur separation comes at the expense of the harmonic spurs introduced by the frequency
multiplier. As such, beneficial use of the frequency multiplier is application specific. Note that the maximum input frequency to the $2 \times$ frequency multipliers must not exceed 125 MHz .

## Input Clock Detectors

The three clock input sections (REFA, REFB, and XTAL) include a dedicated monitor circuit that detects signal presence at the input. The detectors provide input to the switchover control block to support automatic reference switching and holdover operation.

## Switchover/Holdover

The AD9553 supports automatic reference switching and holdover functions. It also supports manual reference switching via an external pin (SEL REFB) or via program control using the serial I/O port. A block diagram of the switchover/holdover capability appears in Figure 21. Note that the mux selects one of the three input signals (REFA, REFB, or XTAL) routing it to the input of the PLL. The selection of an input signal depends on which signals are present along with the contents of Register 0x29[7:6] and the logic level at the SEL REFB pin.

Note that each input signal has a dedicated signal presence detector. Each detector uses the feedback signal from the PLL as a sampling clock (which is always present due to the freerunning VCO). This allows the detectors to determine the presence or absence of the input signals reliably. Note that the mux control logic uses the detector signals directly in order to determine the need for a switch to holdover operation.

Holdover occurs whenever the mux control logic determines that both the REFA and REFB signals are not present, in which case the device selects the XTAL signal if it is present. The exception is when Register $0 \times 29[7: 6]=10$ or 11, which disables the holdover function. If none of the three input signals is present, the device waits until at least one signal becomes present and selects according to the device settings (Register 0x29[7:6] and the logic level at the SEL REFB pin).
When the device is reset (or following a power-up), the internal logic defaults to revertive switchover mode (Register 0x29[7:6] = 00 ). In revertive switchover mode, the device selects the REFA signal whenever it is present. If REFA is not present, then the device selects the REFB signal, if present, but returns to REFA whenever it becomes available. That is, in revertive switchover mode, the device favors REFA. If both REFA and REFB are not present, the device switches to holdover mode.
When programmed for nonrevertive switchover mode (Register 0x29[7:6] = 01), the device selects the REFA signal if it is present. If REFA is not present, then the device selects the REFB signal (if present). Even if REFA becomes available, the device continues to use REFB until REFB fails. That is, in nonrevertive switchover mode, the switch to REFB is permanent unless REFB fails (or unless both REFA and REFB fail, in which case the device switches to holdover mode).

Figure 21. Switchover/Holdover Block Diagram

The user can override the automatic switchover functions (revertive and nonrevertive) and manually select the REFA or REFB signal by programming Register $0 \times 29[7: 6]=10$ or 11 , respectively. Note, however, that the desired signal (REFA or REFB) must be present for the device to select it.
The user can also force the device to switch to REFB by applying a Logic 1 to the external SEL REFB pin. This overrides a REFA selection invoked by either the revertive/nonrevertive logic or when Register 0x29[7:6] = 10. Note, however, that REFB must be present to be selected by the device.

## PLL (PFD, Charge Pump, VCO, Feedback Divider)

The PLL (see Figure 20) consists of a phase-frequency detector (PFD), a partially integrated analog loop filter (see Figure 22), an integrated voltage-controlled oscillator (VCO), and a 20 -bit programmable feedback divider. The PLL generates a 3.35 GHz to 4.05 GHz clock signal based on the frequency of FPFD (see Figure 20) and the feedback divider value, which is phaselocked to the input reference signal.
The PFD of the PLL drives a charge pump that increases, decreases, or holds constant the charge stored on the loop filter capacitors (both internal and external). The stored charge results in a voltage that sets the output frequency of the VCO. The feedback loop of the PLL causes the VCO control voltage to vary in such a way as to phase lock the PFD input signals. Note that the PFD supports input frequencies spanning 13.3 kHz to 100 MHz (implying that input frequencies between 8 kHz and 13.3 kHz must use the $2 \times$ frequency multiplier in the input path).

The PLL has a VCO with 128 frequency bands spanning a range of 3350 MHz to 4050 MHz ( 3700 MHz nominal). However, the actual operating frequency within a particular band depends on the control voltage that appears on the loop filter capacitor. The control voltage causes the VCO output frequency to vary linearly within the selected band. This frequency variability allows the control loop of the PLL to synchronize the VCO output signal with the reference signal applied to the PFD.
Typically, selection of the VCO frequency band (as well as gain adjustment) occurs automatically as part of the device's automatic VCO calibration process, which initiates at power up (or reset). Alternatively, the user can force VCO calibration by first enabling SPI control of VCO calibration (Register 0x0E[2] = 1) and then writing a 1 to the calibrate VCO bit (Register 0x0E[7]).

To facilitate system debugging, the user can override the VCO band setting by first enabling SPI control of VCO band (Register $0 \times 0 \mathrm{E}[0]=1$ ) and then writing the desired value to Register 0x10[7:1].
The feedback divider ( N -divider) sets the frequency multiplication factor of the PLL in integer steps over a 20-bit range. However, the N -divider has a lower limit of 32 , which sets a minimum PLL multiplication factor of 32 .

## AD9553

## Loop Filter

The charge pump in the PFD delivers current to the loop filter (see Figure 22). The main components of the loop filter are external and connect between Pin 16 and Pin 17. Note that to achieve the best jitter performance in applications requiring a loop bandwidth of less than $1 \mathrm{kHz}, \mathrm{C} 1$ and C 2 must have an insulation resistance of at least $500 \Omega \mathrm{~F}$.

There are two recommended sets of external loop filter components (see Table 17) based on the $\mathrm{A}[3: 0]$ pin configuration.

Table 17. External Loop Filter Components

| Pins A[3:0] | $\mathbf{R}(\mathbf{k} \boldsymbol{\Omega})$ | $\mathbf{C 1}$ | $\mathbf{C 2}$ | Loop Bandwidth (kHz) |
| :--- | :--- | :--- | :--- | :--- |
| 0001 to | 6.8 | 47 nF | $1 \mu \mathrm{~F}$ | 0.17 |
| 1100 |  |  |  |  |
| 1101 to | 12 | 51 pF | 220 nF | 75 |
| 1110 |  |  |  |  |
| 1111 | 6.8 | 47 nF | $1 \mu \mathrm{~F}$ | 0.17 |

## PLL Locked Indicator

The PLL provides a status indicator that appears at Pin 20 (LOCKED). When the PLL acquires phase lock, the LOCKED pin switches to a Logic 1 state.
Alternatively, the LOCKED pin serves as a test port allowing the user to monitor one-of-four internal clocks. Register 0x17[3:1] controls the test port as shown in Table 18.

Table 18: LOCKED Pin Output Control

| Register <br> $\mathbf{0 x 1 7 [ 3 : 1 ] ~}$ | LOCKED Pin Output |
| :--- | :--- |
| $0 X X$ | PLL locked indication (default) |
| 100 | Crystal oscillator clock signal |
| 101 | PFD pump-up clock divided-by-2 |
| 110 | PFD reference input clock divided-by-2 |
| 111 | PLL feedback to PFD clock divided-by-2 |
| Output Dividers |  |

## Output Dividers

The output divider section consists of three dividers: $\mathrm{P}_{0}, \mathrm{P}_{1}$, and $\mathrm{P}_{2}$. The $\mathrm{P}_{0}$ divider (or VCO frequency prescaler) accepts the VCO frequency and reduces it by a factor of 5 or 6 (selectable). This brings the frequency down to a range between 558 MHz and 810 MHz .

The output of the $\mathrm{P}_{0}$ divider independently drives the $\mathrm{P}_{1}$ divider and the $P_{2}$ divider. The $P_{1}$ divider establishes the frequency at OUT1 and the $\mathrm{P}_{2}$ divider establishes the frequency at OUT2. The $P_{1}$ and $P_{2}$ dividers are each programmable over a range of 1 to 1023 , which results in a frequency at OUT1 or OUT2 that is an integer submultiple of the frequency at the output of the $P_{0}$ divider.

## Output Driver Configuration

The user has complete control over all configurable parameters of the OUT1 and OUT2 drivers via the OUT1 and OUT2 driver control registers (Register 0x32 and Register 0x34, respectively, as shown in Figure 23). To alter the parameters from their default values, the user must use the SPI port to program the driver control registers as desired.

The OUT1 and OUT2 drivers are configurable in terms of the following parameters:

- Logic family (via mode control)
- Pin function (via mode control but only applies to the CMOS family)
- Polarity (only applies to the CMOS family)
- Drive current
- Power-down

## Output Driver Mode Control

Three mode control bits establish the logic family and pin function of the output drivers. The three bits originate either from Bits[5:3] of Register 0x32 and Register 0x34 or from the decode logic associated with the $\mathrm{OM}[2: 0]$ pins as shown in Figure 23. Note that Bit 0 of Register 0x32 and Register 0x34 determines the source of the three mode control bits for the associated output driver. Specifically, when Bit 0 of the register is Logic 0 (default), the source of the mode control bits for the associated driver is the OM[2:0] pin decoder. When Bit 0 is Logic 1, the source of the mode control bits is from Bits[5:3] of Register 0x32 and Register 0x34.
The mode control bits establish the logic family and output pin function of the associated output driver per Table 19. The logic families include LVDS, LVPECL, and CMOS. Because both output drivers support the LVDS and LVPECL logic families, each driver has two pins to handle the differential signals associated with these two logic families. The OUT1 driver uses the OUT1 and $\overline{\text { OUT1 }}$ pins and the OUT2 driver uses the OUT2 and OUT2 pins. However, the CMOS logic family handles only single-ended signals, thereby requiring only one pin. Even though CMOS only requires one pin, both pins of OUT1 and both pins of OUT2 have a dedicated CMOS driver.
The user has the option to disable (that is, tristate) either or both of the pins for OUT1 and/or OUT2 via the mode control bits (see Table 19, Bit Patterns 001, 010, and 011). Alternatively, the user can make both pins active (see Table 19, Bit Pattern 000 ) to produce two single-ended CMOS output clocks at OUT1 and/or OUT2.

## AD9553

Table 19. Output Mode Control Bits

| Mode Control <br> Bits | Logic <br> Family | Pin Function of the Output <br> Driver |
| :--- | :--- | :--- |
| 000 | CMOS | Both pins active <br> Positive pin active, negative <br> pin tristate <br> 001 |
| 010 | CMOS |  |
| 011 | CMOS | Positive pin tristate, negative <br> pin active |
| 100 | LVDS | Both pins tristate <br> Both pins active <br> 101 |
| 110 | LVPECL | Both pins active |
| 111 | Unused | Unused |

Note that the pin decoder for the OM[2:0] pins generates two sets of mode control bits: one set for the OUT1 driver and another set for the OUT2 driver. The relationship between the logic levels applied to the $\mathrm{OM}[2: 0]$ pins and the resulting mode control bits appears in Table 20.
Table 20. OM[2:0] Pin Decoder

| Pins OM[2:0] | Mode Control Bits |  |
| :--- | :--- | :--- |
|  | OUT1 | OUT2 |
| 000 | 101 | 101 |
| 001 | 101 | 100 |
| 010 | 100 | 101 |
| 011 | 101 | 001 |
| 100 | 100 | 100 |
| 101 | 100 | 001 |
| 110 | 001 | 100 |
| 111 | 001 | 001 |

This decoding scheme allows the $\mathrm{OM}[2: 0]$ pins to establish a matrix of logic family selections for the OUT1 and OUT2 drivers as shown in Table 21. Note that when the OM[2:0] pins select the CMOS logic family, only the positive pin active, negative pin tristate output driver pin function option is available.

Table 21. Logic Family Assignment via the OM[2:0] Pins

| Pins OM[2:0] | Logic Family |  |
| :--- | :--- | :--- |
|  | OUT1 | OUT2 |
| 000 | LVPECL | LVPECL |
| 001 | LVPECL | LVDS |
| 010 | LVDS | LVPECL |
| 011 | LVPECL | CMOS |
| 100 | LVDS | LVDS |
| 101 | LVDS | CMOS |
| 110 | CMOS | LVDS |
| 111 | CMOS | CMOS |

## AD9553

Figure 23. Output Driver Control

## Output Driver Polarity (CMOS)

When the mode control bits indicate the CMOS logic family (see Table 19), the user has control of the logic polarity associated with each CMOS output pin. Driver polarity defines how the logic level (Logic 1 or Logic 0 ) at a CMOS output pin relates to the logic state (Logic True or Logic False). Normal polarity equates Logic $1 /$ Logic 0 to Logic True/Logic False, while inverted polarity equates Logic 0/Logic 1 to Logic True/Logic False. Bits[2:1] of the OUT1 and OUT2 driver control registers control the CMOS polarity of the associated output driver (see Figure 23).

## Output Drive Strength (CMOS or LVDS)

When the mode bits indicate the CMOS or LVDS logic family (see Table 19), the user can select whether the output driver uses weak or strong drive capability. Bit 7 of the OUT1 and OUT2 driver control registers control the drive strength of the associated output driver (see Figure 23). In the case of the CMOS family, the strong setting allows for driving increased capacitive loads. In the case of the LVDS family, the nominal weak and strong drive currents are 3.5 mA and 7 mA , respectively.

## Output Power Down

The AD9553 supports the option of independent power-down of the output drivers. Bit 6 of the OUT1 and OUT2 driver control registers controls the power-down function (see Figure 23). When Bit 6 is Logic 0 , the associated output driver is active. When Bit 6 is Logic 1, the associated output driver is in power-down mode.

## JITTER TOLERANCE

Jitter tolerance is the ability of the AD9553 to maintain lock in the presence of sinusoidal jitter. The AD9553 meets the input jitter tolerance mask per Telcordia GR-253-CORE (see Figure 24). The acceptable jitter tolerance is the region above the mask. The trace showing the performance of the AD9553 in Figure 24 represents the limitations of the test equipment because the AD9553 did not indicate loss of lock, even with the test equipment injecting its maximum jitter level.

Figure 24. Jitter Tolerance

## OUTPUT/INPUT FREQUENCY RELATIONSHIP

The frequency at OUT1 and OUT2 depends on the frequency at the input to the PLL, the PLL feedback divider value ( N ), and the output divider values ( $\mathrm{P}_{0}, \mathrm{P}_{1}$, and $\mathrm{P}_{2}$ ). The equations that define the frequency at OUT1 and OUT2 (fout1 and fout2, respectively) are as follows:

$$
\begin{aligned}
& f_{\text {OUT1 }}=F P F D\left(\frac{N}{P_{0} \times P_{1}}\right) \\
& f_{\text {OUT2 }}=F P F D\left(\frac{N}{P_{0} \times P_{2}}\right)
\end{aligned}
$$

where:
$F P F D$ is the frequency at the reference input of the PFD.
$N$ is the feedback divider value.
$P_{0}$ is the VCO prescaler divider value.
$P_{1}$ is the OUT1 divider value.
$P_{2}$ is the OUT2 divider value.
The operating frequency range of the PFD places a limitation on FPFD as follows:

$$
13.3 \mathrm{kHz} \leq F P F D \leq 100 \mathrm{MHz}
$$

Note that for applications using the frequency selection pins in conjunction with the XTAL input for the holdover function, the maximum value of FPFD is 50 MHz (twice the 25 MHz default crystal frequency).
FPFD depends on the input frequency to the AD9553, the configuration of the multiplexers for the $/ 5$ prescaler and $2 \times$ frequency multiplier, and the value of the $R_{x}$ divider (either $R_{A}$, $\mathrm{R}_{\mathrm{B}}$, or $\mathrm{R}_{\mathrm{xo}}$ ) as follows:

$$
F P F D=f_{X} \times \frac{K}{R_{X}}
$$

where:
$f_{X}$ is equal to $\mathrm{f}_{\text {REFA }}, \mathrm{f}_{\text {REFB }}$, or $\mathrm{f}_{\mathrm{XTAL}}$.
$K$ is the scale factor per Table 22.
$F P F D$ is the frequency at the input to the phase frequency detector.

Table 22. K as a Function of Input Multiplexer Configuration

| Input | $\mathbf{1 5}$ | $\mathbf{2 \times}$ | K |
| :--- | :--- | :--- | :--- |
| REFA | Bypassed | Bypassed | 1 |
|  | Active | Bypassed | $1 / 5$ |
|  | Bypassed | Active | 2 |
|  | Active | Active | $2 / 5$ |
| REFB | Bypassed | Bypassed | 1 |
|  | Active | Bypassed | $1 / 5$ |
|  | Bypassed | Active | 2 |
|  | Active | Active | $2 / 5$ |
| XTAL | N/A | N/A | 2 |

## AD9553

This leads to the complete frequency translation formula

$$
\begin{aligned}
& f_{\text {OUT } 1}=f_{X}\left(\frac{K}{R_{X}}\right)\left(\frac{N}{P_{0} \times P_{1}}\right) \\
& f_{\text {OUT } 2}=f_{X}\left(\frac{K}{R_{X}}\right)\left(\frac{N}{P_{0} \times P_{2}}\right)
\end{aligned}
$$

Specific numeric constraints apply as follows. Note that the symbol $\in$ indicates that the constraint is an element of one in the series from the list within the curly brackets.

$$
\begin{aligned}
& K \in\left\{\frac{1}{5}, \frac{2}{5}, 1,2\right\} \\
& R_{X} \in\{1,2, \cdots, 16384\} \\
& N \in\{32,33, \cdots, 1048576\} \\
& P_{0} \in\{5,6\} \\
& P_{1} \in\{1,2, \cdots, 63\} \\
& P_{2} \in\{1,2, \cdots, 63\}
\end{aligned}
$$

Additional constraints apply. One constraint is related to the VCO and the other to the $2 \times$ frequency multipliers in the REFA and REFB paths. The VCO constraint is a consequence of its limited bandwidth. However, the $2 \times$ frequency multiplier constraint only applies when the / 5 prescalers are bypassed, but it also requires that $\mathrm{R}_{\mathrm{A}}$ and $\mathrm{R}_{\mathrm{B}}$ are large enough to satisfy the FPFD constraint. The additional constraints are as follows:

$$
\begin{aligned}
& 3350 \mathrm{MHz} \leq \mathrm{f}_{\text {OUT } 1} \times \mathrm{P}_{0} \times \mathrm{P}_{1} \leq 4050 \mathrm{MHz} \\
& 3350 \mathrm{MHz} \leq \mathrm{f}_{\text {OUT2 }} \times \mathrm{P}_{0} \times \mathrm{P}_{2} \leq 4050 \mathrm{MHz} \\
& \mathrm{f}_{\mathrm{REFA} / \mathrm{B}} \leq 125 \mathrm{MHz}(2 \times \text { multiplier with } / 5 \text { bypassed })
\end{aligned}
$$

Generally, the AD9553 is for applications in which $f_{\text {REFA }}$ and $f_{\text {REFB }}$ are the same frequency, so the multiplexers in the REFA and REFB paths share identical configurations. This, in conjunction with the crystal frequency ( $\mathrm{f}_{\mathrm{xTAL}}$ ), results in the following relationship between the $\mathrm{R}_{\mathrm{A}}$ and Rxo dividers (here K is the scale factor for the REFA path).

$$
\frac{2 \times f_{X T A L}}{f_{R E F A}}=K \times \frac{R_{X O}}{R_{A}}
$$

Note that for pin-programmed holdover applications using the crystal, the crystal frequency must be 25 MHz . Under these circumstances, the above equation simplifies as follows:

$$
\frac{50 \times 10^{6}}{f_{R E F A}}=K \times \frac{R_{X O}}{R_{A}}
$$

## CALCULATING DIVIDER VALUES

This section describes the process of calculating the divider values when given a specific $f_{\text {OUT } 1} / f_{\text {REF }}$ ratio ( $\mathrm{f}_{\text {REF }}$ is the frequency of either the REFA or REFB input signal source or the external crystal resonator). This description is in general terms, but it includes a specific example for clarity. The example assumes a frequency control pin setting of $\mathrm{A}[3: 0]=1011$ (see Table 14) and $\mathrm{Y}[5: 0]=011100$ (see Table 15), yielding the following:
$f_{\text {REF }}=125 \mathrm{MHz}$
$f_{\text {outl }}=155.52 \mathrm{MHz}$
Follow these steps to calculate the divider values.

1. Determine the output divide factor (ODF).

Note that the VCO frequency ( $\mathrm{f}_{\mathrm{vco}}$ ) spans 3350 MHz to 4050 MHz . The ratio, $\mathrm{f}_{\mathrm{vco}} / \mathrm{fout}_{\mathrm{fot}}$, indicates the required ODF. Given the specified value of fouti $(155.52 \mathrm{MHz})$ and the range of $\mathrm{f}_{\mathrm{vco}}$, the ODF spans a range of 21.54 to 26.04. The ODF must be an integer, which means that ODF is $22,23,24,25$, or 26 .
2. Determine suitable values for $P_{0}, P_{1}$ and $f_{v c o}$.

The ODF is the product of the two output dividers $\mathrm{P}_{0}$ and $P_{1}(O D F=P 0 P 1)$. However, $P_{0}$ is constrained to 5 or 6 (see the Output/Input Frequency Relationship section), which means that there are only two possibilities for ODF in this example: $\mathrm{ODF}=24\left(\mathrm{P}_{0}=6, \mathrm{P}_{1}=4\right)$ and $\mathrm{ODF}=25\left(\mathrm{P}_{0}=5\right.$, $P_{1}=5$ ). These two ODF values result in the only VCO frequencies that satisfy the 155.52 MHz requirement for OUT1 ( 3732.48 MHz for ODF $=24$ and 3888 MHz for $\mathrm{ODF}=25$ ). The results appear below. Note that the first result agrees with Table 15 in the Preset Frequencies section).

$$
\begin{aligned}
& \mathrm{P}_{0}=6, \mathrm{P}_{1}=4\left(\mathrm{f}_{\mathrm{vco}}=3732.48 \mathrm{MHz}\right) \\
& \mathrm{P}_{0}=5, \mathrm{P}_{1}=5\left(\mathrm{f}_{\mathrm{vco}}=3888 \mathrm{MHz}\right)
\end{aligned}
$$

3. Determine the boundary conditions on $\mathrm{N}, \mathrm{K}$, and R. Because of the architecture of the PLL, FPFD must be an integer submultiple of the VCO frequency as shown in the following equation. Note that N is an integer and is the 20-bit value of the N -divider.

$$
F P F D=\frac{f_{V C O}}{N}
$$

This relationship leads to boundary conditions on N because N must be an integer that satisfies $\mathrm{N}=\mathrm{f}_{\mathrm{vco}} /$ FPFD. The limits on FPFD ( 13.3 kHz to 100 MHz ) combined with the results for fvco from Step 2 yield

$$
\begin{aligned}
& \mathrm{N}=38 \ldots 280,637(\text { for } \mathrm{fvco}=3732.48 \mathrm{MHz}) \\
& \mathrm{N}=39 \ldots 292,330\left(\text { for } \mathrm{f}_{\mathrm{vco}}=3888 \mathrm{MHz}\right)
\end{aligned}
$$

Note that FPFD also relates to the input frequency, $\mathrm{f}_{\text {ReF, }}$, per the following equation. Here, R is the 14 -bit integer division factor of the input divider $\left(R_{A}\right.$ or $\left.R_{B}\right)$, while $K$ is the scale factor associated with the optional $2 \times$ multiplier and divide-by-five functions. Note that K can only be one of four values: $1 / 5,2 / 5,1$, or 2 .

$$
F P F D=f_{R E F}\left(\frac{K}{R}\right)
$$

This relationship leads to boundary conditions on R because $\mathrm{R} / \mathrm{K}=\mathrm{f}_{\text {REF }} / \mathrm{FPFD}$ where R must be an integer and K can only be $1 / 5,2 / 5,1$, or 2 . The limits on FPFD ( 13.3 kHz to 100 MHz ) combined with the given value of $\mathrm{f}_{\text {REF }}$ yield the following bounds on R. Note that for $\mathrm{K}=2$, the upper bound on R is limited by its 14 -bit range.

$$
\begin{aligned}
& \mathrm{R}=1 \ldots 1,879(\text { for } \mathrm{K}=1 / 5) \\
& \mathrm{R}=1 \ldots 3,759(\text { for } \mathrm{K}=2 / 5) \\
& \mathrm{R}=2 \ldots 9,398(\text { for } \mathrm{K}=1) \\
& \mathrm{R}=3 \ldots 16,384(\text { for } \mathrm{K}=2)
\end{aligned}
$$

4. Relate $\mathrm{N}, \mathrm{K}$, and R to the frequency requirements. The two FPFD equations in Step 3 show that $\mathrm{f}_{\mathrm{VCO}}$ and $\mathrm{f}_{\text {REF }}$ relate as

$$
\frac{f_{V C O}}{f_{R E F}}=\frac{N K}{R}
$$

Note that $\mathrm{f}_{\text {REF }}$ is a known quantity $(125 \mathrm{MHz})$ and the VCO frequencies were determined in Step 2 as 3732.48 MHz and 3888 MHz . Based on these values of $\mathrm{f}_{\text {REF }}$ and $\mathrm{f}_{\mathrm{VCO}}$

$$
\frac{3732.48}{125}=\frac{N K}{R} \quad \text { or } \quad \frac{3888}{125}=\frac{N K}{R}
$$

5. Determine N, K. and R.

For $\mathrm{f}_{\mathrm{Vco}}=3888 \mathrm{MHz}$, an obvious solution is $\mathrm{K}=1, \mathrm{R}=125$ and $\mathrm{N}=3888$, which satisfies the constraint on both N and R and yields $\mathrm{FPFD}=1 \mathrm{MHz}$.

For $\mathrm{f}_{\mathrm{VCO}}=3732.48 \mathrm{MHz}$, an obvious solution is $\mathrm{N}=373,248$, $\mathrm{K}=1$ and $\mathrm{R}=12,500$. This choice, however, violates the constraints on both N and R in Step 3.

A simple remedy is to divide both N and R by a common factor. In this particular case, four is the greatest common factor of N and R. Dividing by four leads to $\mathrm{N}=93,312, \mathrm{~K}=1$, and $\mathrm{R}=$ $3,125(\mathrm{~K}=1)$, satisfying the constraint on N and R , and yielding FPFD $=40 \mathrm{kHz}$. Note that to match the values given in the Preset Frequencies section, FPFD must be 16 kHz . To accomplish this, keep $\mathrm{R}=3,125$, but choose $\mathrm{K}=2 / 5$ (see Table 14 ). This changes N to 233,280, which agrees with Table 16. In summary, if one chooses $\mathrm{f}_{\mathrm{VCO}}=3732.48 \mathrm{MHz}$, then the solution set that matches the tables in the Preset Frequencies section is

$$
\begin{aligned}
& \mathrm{P}_{0}=6 \\
& \mathrm{P}_{1}=4 \\
& \mathrm{~N}=233,280 \\
& \mathrm{R}=3,125 \\
& \mathrm{~K}=2 / 5 \\
& \mathrm{FPFD}=16 \mathrm{kHz}
\end{aligned}
$$

If one chooses $\mathrm{fvco}=3888 \mathrm{MHz}$, then a possible solution is

$$
\begin{aligned}
& \mathrm{P}_{0}=5 \\
& \mathrm{P}_{1}=5 \\
& \mathrm{~N}=3888 \\
& \mathrm{R}=125 \\
& \mathrm{~K}=1 \\
& \mathrm{FPFD}=1 \mathrm{MHz}
\end{aligned}
$$

6. If applicable, determine $\mathrm{R}_{\mathrm{x} \text {, }}$, the XTAL divider value. The value of $\mathrm{Rxo}_{\text {xo }}$ depends on the value of $\mathrm{f}_{\text {REF }}, \mathrm{K}$, and R from Step 5, as follows:

$$
R_{X O}=\left(\frac{50 \times 10^{6}}{f_{\text {REF }}}\right)\left(\frac{R}{K}\right)
$$

Given that $\mathrm{f}_{\text {REF }}=125 \mathrm{MHz}$, the two results from Step 5 lead to

$$
\begin{aligned}
& R_{X O}=3125(\text { for } \mathrm{R}=3125 \text { and } \mathrm{K}=2 / 5) \\
& R_{X O}=50(\text { for } \mathrm{R}=125 \text { and } \mathrm{K}=1)
\end{aligned}
$$

## LOW DROPOUT (LDO) REGULATORS

The AD9553 is powered from a single 3.3 V supply and contains on-chip LDO regulators for each function to eliminate the need for external LDOs. To ensure optimal performance, each LDO output should have a $0.47 \mu \mathrm{~F}$ capacitor connected between its access pin and ground.

## AUTOMATIC POWER-ON RESET

The AD9553 has an internal power-on reset circuit (see Figure 25). At power-up, an 800 pF capacitor momentarily holds a Logic 0 at the active low input of the reset circuitry. This ensures that the device is held in a reset state ( $\sim 250 \mu \mathrm{~s}$ ) until the capacitor charges sufficiently via the $100 \mathrm{k} \Omega$ pull-up resistor and $200 \mathrm{k} \Omega$ series resistor. Note that when using a low impedance source to drive the $\overline{\operatorname{RESET}}$ pin, be sure that the source is either tristate or Logic 0 at power-up. Otherwise, the device may not calibrate properly.

Figure 25. Power-On Reset

## AD9553

## APPLICATIONS INFORMATION

## THERMAL PERFORMANCE

The AD9553 is specified for a case temperature ( $\mathrm{T}_{\text {CASE }}$ ). To ensure that $\mathrm{T}_{\text {CASE }}$ is not exceeded, an airflow source can be used. Use the following equation to determine the junction temperature on the application PCB:

$$
T_{J}=T_{C A S E}+\left(\Psi_{I T} \times P_{D}\right)
$$

where:
$T_{I}$ is the junction temperature ( ${ }^{\circ} \mathrm{C}$ ).
$T_{\text {CASE }}$ is the case temperature $\left({ }^{\circ} \mathrm{C}\right)$ measured by the customer at the top center of the package.
$\Psi_{J T}$ is the value indicated in Table 23.
$P_{D}$ is the power dissipation (see the Power Consumption section).

Values of $\theta_{\mathrm{IA}}$ are provided for package comparison and PCB design considerations. $\theta_{\mathrm{JA}}$ can be used for a first-order approximation of $\mathrm{T}_{J}$ using the following equation:

$$
T_{I}=T_{A}+\left(\theta_{I A} \times P_{D}\right)
$$

where $T_{A}$ is the ambient temperature $\left({ }^{\circ} \mathrm{C}\right)$.
Values of $\theta_{\mathrm{JC}}$ are provided for package comparison and PCB design considerations when an external heat sink is required.
Values of $\theta_{J B}$ are provided for package comparison and PCB design considerations.

Table 23. Thermal Parameters for the 32-Lead LFCSP Package

| Symbol | Description | Value ${ }^{1}$ | Unit |
| :---: | :---: | :---: | :---: |
| $\theta_{\text {JA }}$ | Junction-to-ambient thermal resistance, $0 \mathrm{~m} / \mathrm{sec}$ airflow per JEDEC JESD51-2 (still air) | 41.6 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\theta_{\text {Jма }}$ | Junction-to-ambient thermal resistance, $1.0 \mathrm{~m} / \mathrm{sec}$ airflow per JEDEC JESD51-6 (moving air) | 36.4 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\theta_{\text {Jма }}$ | Junction-to-ambient thermal resistance, $2.5 \mathrm{~m} / \mathrm{sec}$ airflow per JEDEC JESD51-6 (moving air) | 32.6 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |
| $\theta_{\text {лв }}$ | Junction-to-board thermal resistance, $0 \mathrm{~m} / \mathrm{sec}$ airflow per JEDEC JESD51-8 (still air) | 24.2 | ${ }^{\circ} \mathrm{C} / \mathrm{W}$ |

[^4]
## SERIAL CONTROL PORT

The AD9553 serial control port is a flexible, synchronous, serial communications port that allows an easy interface to many industry-standard microcontrollers and microprocessors. Single or multiple byte transfers are supported, as well as MSB first or LSB first transfer formats. The AD9553 serial control port is configured for a single bidirectional I/O pin (SDIO only). The serial control port uses 16-bit instructions, which allows access to the entire register address range ( $0 \times 00$ to $0 \times 34$ ).
The serial control port has two types of registers: read-only and buffered. Read-only registers are nonbuffered and ignore write commands. All writable registers are buffered (also referred to as mirrored) and require an I/O update to transfer the new values from a temporary buffer on the chip to the actual register. To invoke an I/O update, write a 1 to the I/O update bit found in Register 0x05[0]. Because any number of bytes of data can be changed before issuing an update command, the update simultaneously enables all register changes occurring since any previous update.

## SERIAL CONTROL PORT PIN DESCRIPTIONS

The serial data clock (SCLK) is the serial shift clock. This pin is an input. SCLK is used to synchronize serial control port reads and writes. Write data bits are registered on the rising edge of this clock, and read data bits are registered on the falling edge.
The digital serial data input/output (SDIO) pin is a dualpurpose pin that acts as input only or as an input/output. The AD9553 defaults to bidirectional pins for I/O.
The chip select bar $(\overline{\mathrm{CS}})$ is an active low control that gates the read and write cycles. When $\overline{\mathrm{CS}}$ is high, SDIO is in a high impedance state. See the Operation of the Serial Control Port section on the use of the $\overline{\mathrm{CS}}$ pin in a communication cycle.

Figure 26. Serial Control Port

## OPERATION OF THE SERIAL CONTROL PORT

## Framing a Communication Cycle with $\overline{C S}$

The $\overline{\mathrm{CS}}$ line gates the communication cycle (a write or a read operation). $\overline{\mathrm{CS}}$ must be brought low to initiate a communication cycle.
The $\overline{\mathrm{CS}}$ stall high function is supported in modes where three or fewer bytes of data (plus instruction data) are transferred. Bits[W1:W0] must be set to 00,01 , or 10 (see Table 24). In these modes, $\overline{\mathrm{CS}}$ may temporarily return high on any byte boundary, allowing time for the system controller to process the next byte. $\overline{\mathrm{CS}}$ can go high on byte boundaries only and can go high during either part (instruction or data) of the transfer. During this period,
the serial control port state machine enters a wait state until all data has been sent. If the system controller decides to abort before the complete transfer of all the data, the state machine must be reset either by completing the remaining transfer or by returning the $\overline{\mathrm{CS}}$ line low for at least one complete SCLK cycle (but fewer than eight SCLK cycles). A rising edge on the $\overline{C S}$ pin on a nonbyte boundary terminates the serial transfer and flushes the buffer.

Table 24. Byte Transfer Count

| Bit W1 | Bit W0 | Bytes to Transfer <br> (Excluding the 2-Byte Instruction) |
| :--- | :--- | :--- |
| 0 | 0 | 1 |
| 0 | 1 | 2 |
| 1 | 0 | 3 |
| 1 | 1 | Streaming mode |

In the streaming mode (Bits[W1:W0] = 11), any number of data bytes can be transferred in a continuous stream. The register address is automatically incremented or decremented (see the MSB/LSB First Transfers section). $\overline{\mathrm{CS}}$ must be raised at the end of the last byte to be transferred, thereby ending the stream mode.

## Communication Cycle—Instruction Plus Data

There are two parts to a communication cycle with the AD9553. The first part writes a 16-bit instruction word into the AD9553, coincident with the first 16 SCLK rising edges. The instruction word provides the AD9553 serial control port with information regarding the data transfer, which is the second part of the communication cycle. The instruction word defines whether the upcoming data transfer is a read or a write, the number of bytes in the data transfer, and the starting register address for the first byte of the data transfer.

## Write

If the instruction word is for a write operation (Bit $\mathrm{I} 15=0$ ), the second part is the transfer of data into the serial control port buffer of the AD9553. The length of the transfer ( 1,2 , or 3 bytes; or streaming mode) is indicated by two bits (Bits[W1:W0]) in the instruction byte. The length of the transfer indicated by (Bits[W1:W0]) does not include the 2-byte instruction. $\overline{\mathrm{CS}}$ can be raised after each sequence of eight bits to stall the bus (except after the last byte, where it ends the cycle). When the bus is stalled, the serial transfer resumes when $\overline{\mathrm{CS}}$ is lowered. Stalling on nonbyte boundaries resets the serial control port.

## Read

If the instruction word is for a read operation (Bit $\mathrm{I} 15=1$ ), the next $\mathrm{N} \times 8$ SCLK cycles clock out the data from the address specified in the instruction word, where $N$ is $1,2,3$, or 4 , as determined by Bits[W1:W0]. In this case, 4 is used for streaming mode, where four or more words are transferred per read. The data read back is valid on the falling edge of SCLK.

The default mode of the AD9553 serial control port is bidirectional mode, and the data readback appears on the SDIO pin.

## AD9553

By default, a read request reads the register value that is currently in use by the AD9553. However, setting Register $0 \times 04[0]=1$ causes the buffered registers to be read instead. The buffered registers are the ones that take effect during the next I/O update.

Figure 27. Relationship Between the Serial Control Port Register Buffers and the Control Registers

## INSTRUCTION WORD (16 BITS)

The MSB of the instruction word (see Table 25) is R/ $\bar{W}$, which indicates whether the instruction is a read or a write. The next two bits, W1 and W0, are the transfer length in bytes. The final 13 bits are the address bits (Address Bits[A12:A0]) at which the read or write operation is to begin.
For a write, the instruction word is followed by the number of bytes of data indicated by Bits[W1:W0], which is interpreted according to Table 24.
Address Bits[A12:A0] select the address within the register map that is written to or read from during the data transfer portion of the communication cycle. The AD9553 uses all of the 13-bit address space. For multibyte transfers, this address is the starting byte address.

## MSB/LSB FIRST TRANSFERS

The AD9553 instruction word and byte data can be MSB first or LSB first. The default for the AD9553 is MSB first. The LSB first mode can be set by writing a 1 to Register $0 \times 00[6]$ and requires that an I/O update be executed. Immediately after the LSB first bit is set, all serial control port operations are changed to LSB first order.

When MSB first mode is active, the instruction and data bytes must be written from MSB to LSB. Multibyte data transfers in MSB first format start with an instruction byte that includes the register address of the most significant data byte. Subsequent data bytes must follow in order from high address to low address. In MSB first mode, the serial control port internal address generator decrements for each data byte of the multibyte transfer cycle.

When LSB first = 1 (LSB first), the instruction and data bytes must be written from LSB to MSB. Multibyte data transfers in LSB first format start with an instruction byte that includes the register address of the least significant data byte followed by multiple data bytes. The serial control port internal byte address generator increments for each data byte of the multibyte transfer cycle.
The AD9553 serial control port register address decrements from the register address just written toward $0 x 00$ for multibyte I/O operations if the MSB first mode is active (default). If the LSB first mode is active, the serial control port register address increments from the address just written toward 0x34 for multibyte I/O operations.
Unused addresses are not skipped during multibyte I/O operations. The user should write the default value to a reserved register and should write only zeros to unmapped registers. Note that it is more efficient to issue a new write command than to write the default value to more than two consecutive reserved (or unmapped) registers.

Table 25. Serial Control Port, 16-Bit Instruction Word, MSB First MSB

Table 26. Definition of Terms Used in Serial Control Port Timing Diagrams

| Parameter | Description |
| :--- | :--- |
| $t_{\text {CLK }}$ | Period of SCLK |
| $t_{\text {DV }}$ | Read data valid time (time from falling edge of SCLK to valid data on SDIO) |
| $t_{D S}$ | Setup time between data and rising edge of SCLK |
| $t_{D H}$ | Hold time between data and rising edge of SCLK |
| $t_{S}$ | Setup time between $\overline{\mathrm{CS}}$ and SCLK |
| $\mathrm{t}_{\mathrm{H}}$ | Hold time between $\overline{\mathrm{CS}}$ and SCLK |
| $\mathrm{t}_{\text {HIGH }}$ | Minimum period that SCLK should be in a logic high state |
| $\mathrm{t}_{\text {LOw }}$ | Minimum period that SCLK should be in a logic low state |

## AD9553

## REGISTER MAP DESCRIPTIONS

Control bit functions are active high unless stated otherwise. Register address values are always hexadecimal unless otherwise indicated.

## Serial Port Control (Register 0x00 to Register 0x05)

Table 28.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x00 | 7 | Unused | Forced to Logic 0 internally, which enables 3-wire mode only. |
|  | 6 | LSB first | $\begin{aligned} & \text { Bit order for SPI port. } \\ & 0=\text { most significant bit and byte first (default). } \\ & 1=\text { least significant bit and byte first. } \\ & \hline \end{aligned}$ |
|  | 5 | Soft reset | Software initiated reset (register values set to default). This is an autoclearing bit. |
|  | 4 | Unused | Forced to Logic 1 internally, which enables 16-bit mode (the only mode supported by the device). |
|  | [3:0] | Unused | Mirrored version of the contents of Register 0x00[7:4] (that is, Bits[3:0] = Bits[7:4]). |
| 0x04 | [7:1] | Unused | Unused. |
|  | 0 | Readback control | For buffered registers, serial port readback reads from actual (active) registers instead of from the buffer. <br> $0=$ reads values currently applied to the internal logic of the device (default). <br> 1 = reads buffered values that take effect on next assertion of I/O update. |
| 0x05 | [7:1] | Unused | Unused. |
|  | 0 | I/O update | Writing a 1 to this bit transfers the data in the serial I/O buffer registers to the internal control registers of the device. This is an autoclearing bit. |

## PLL Charge Pump and PFD Control (Register 0x0A to Register 0x0D)

Table 29.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x0A | [7:0] | Charge pump current control | These bits set the magnitude of the PLL charge pump current. The granularity is $\sim 3.5 \mu \mathrm{~A}$ with a full-scale magnitude of $\sim 900 \mu \mathrm{~A}$. Default is $0 \times 80$, or $\sim 448 \mu \mathrm{~A}$. Register 0x0A is ineffective unless Register 0x0B[7] = 1 . |
| 0x0B | 7 | Enable SPI control of charge pump current | Controls the functionality of Register 0x0A. <br> $0=$ charge pump current based on $\mathrm{A}[3: 0]$ and $\mathrm{Y}[5: 0]$ pins per Table 16 (default). <br> 1 = charge pump current defined by Register 0x0A. |
|  | 6 | Enable SPI control of antibacklash period | Controls the functionality of Register 0x0D[7:6]. <br> $0=$ the device automatically controls the antibacklash period (default). <br> 1 = antibacklash period defined by Register 0x0D[7:6]. |
|  | [5:4] | Charge pump mode | Controls the mode of the PLL charge pump. $00=$ tristate. <br> 01 = pump up. <br> 10 = pump down. <br> 11 = normal (default). |
|  | 3 | Disable charge pump | Disables the charge pump (functionally equivalent to Register $0 \times 0 B[5: 4]=00$ ). $0=$ normal operation (default). <br> 1 = disable charge pump. |
|  | 2 | PFD feedback input edge control | Selects the polarity of the active edge of the PLL's feedback input. $0=$ positive edge (default). <br> 1 = negative edge. |
|  | 1 | PFD reference input edge control | Selects the polarity of the active edge of the PLL's reference input. $0=$ positive edge (default). <br> 1 = negative edge. |
|  | 0 | Force VCO to midpoint frequency | Selects VCO control voltage functionality. $0=$ normal VCO operation (default). <br> 1 = force VCO control voltage to midscale. |

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x0C | [7:3] | Unused | Unused. |
|  | [2:0] | Charge Pump Clock Div | Enables the PFD clock dividers (used for test only via test mux). $000=$ test clocks disabled, normal operation (default). <br> 001 = divide feedback clock by 2. <br> $010=$ divide PFD reference input clock by 2 . <br> 011 = divide PFD reference input and feedback clocks by 2. <br> $100=$ divide pump-up clock by 2 . <br> 101 = divide pump-up and feedback clocks by 2. <br> $110=$ divide pump-up and PFD reference input clocks by 2. <br> 111 = divide feedback, pump-up, and pump-down clocks by 2. |
| 0x0D | [7:6] | Antibacklash control | Controls the PFD antibacklash period of the PLL. These bits are ineffective unless Register $0 \times 0 \mathrm{~B}[6]=1$. $00=\text { minimum (default). }$ $01 \text { = low. }$ $10=\text { high. }$ <br> 11 = maximum. |
|  | [5:1] | Unused | Unused. |
|  | 0 | PLL lock detector powerdown | Controls power-down of the PLL lock detector. $0=$ lock detector active (default). <br> 1 = lock detector powered down. |

## VCO Control (Register 0x0E to Register 0x10)

Table 30.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x0E | 7 | Calibrate VCO | Initiates VCO calibration (this is an autoclearing bit). This bit is ineffective unless Register 0x0E[2] $=1$. |
|  | 6 | Enable ALC | Enables automatic level control (ALC) of the VCO. <br> 0 = Register 0x0F[7:2] defines the VCO level. <br> 1 = the device automatically controls the VCO level (default). |
|  | [5:3] | ALC threshold | Controls the VCO ALC threshold detector level from minimum (000) to maximum (111). The default is 110 . |
|  | 2 | Enable SPI control of VCO calibration | Enables the functionality of Register 0x0E[7]. <br> $0=$ the device automatically performs VCO calibration (default). <br> 1 = VCO calibration controlled by Register 0x0E[7]. |
|  | 1 | Boost VCO supply | Selects VCO supply voltage. <br> $0=$ normal supply voltage (default). <br> 1 = increase supply voltage by 100 mV . |
|  | 0 | Enable SPI control of VCO band setting | Controls VCO band setting functionality. <br> $0=$ the device automatically selects the VCO band (default). <br> 1 = VCO band defined by Register 0x10[7:1]. |
| 0x0F | [7:2] | VCO level control | Controls the VCO amplitude from minimum (00 0000) to maximum (11 1111). The default is 100000 . <br> These bits are ineffective unless Register $0 \times 0 \mathrm{E}[6]=0$. |
|  | [1:0] | Unused | Unused. |
| 0x10 | [7:1] | VCO band control | Controls the VCO frequency band from minimum (000 0000) to maximum (111 1111). The default is 1000000. <br> These bits are ineffective unless Register $0 \times 0 \mathrm{E}[0]=1$. |
|  | 0 | Unused | Unused. |

## AD9553

## PLL and Output Frequency Control (Register 0x1 1 to Register 0x19)

Table 31.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x11 | [7:0] | Unused | Unused. |
| $0 \times 12$ | [7:0] | Feedback divider (N) | Bits[19:12] of the 20-bit feedback divider ( N ). |
| 0x13 | [7:0] | Feedback divider (N) | Bits[11:4] of the 20-bit feedback divider (N). |
| 0x14 | [7:4] | Feedback divider (N) | Bits[3:0] of the 20-bit feedback divider ( N ). Default is $\mathrm{N}=0 \times 80000(524,288)$. The feedback divider bits are ineffective unless Register 0x14[3] $=1$. |
|  | 3 | Enable SPI control of feedback divider | Enables SPI port control of the feedback divider value (N). $0=$ The $\mathrm{A}[3: 0]$ and $\mathrm{Y}[5: 0]$ pins define N per Table 16 (default). <br> $1=$ The 20-bit value in the feedback divider register defines $N$. |
|  | 2 | Enable SPI control of output dividers | Enables SPI port control of the output dividers $\mathrm{P}_{0}, \mathrm{P}_{1}$, and $\mathrm{P}_{2}$. $0=$ The $Y[5: 0]$ pins define the output divider values per Table 15 (default). <br> 1 = The SPI port registers ( $0 \times 15,0 \times 16,0 \times 18$ ) define the output divider values. |
|  | 1 | Unused | Unused. |
|  | 0 | Reset PLL | Controls initialization of the PLL. <br> $0=$ normal operation (default). <br> 1 = resets the counters and logic associated with the PLL but does not affect the output dividers. |
| 0x15 | [7:0] | $\mathrm{P}_{1}$ divider | Bits[9:2] of the 11-bit $\mathrm{P}_{1}$ divider. |
| 0x16 | [7:6] | $\mathrm{P}_{1}$ divider | Bits[1:0] of the 11-bit $P_{1}$ divider (the default $P_{1}$ divider register value is 128 decimal). The $P_{1}$ divider bits are ineffective unless Register $0 \times 14[2]=1$. |
|  | [5:0] | $\mathrm{P}_{2}$ divider | Bits[9:4] of the 11-bit $P_{2}$ divider. |
| $0 \times 17$ | [7:4] | $\mathrm{P}_{2}$ divider | Bits[3:0] of the 11-bit $P_{2}$ divider. <br> The $P_{2}$ divider bits are ineffective unless Register $0 \times 14[2]=1$. |
|  | 3 | Enable test port | Enables use of the LOCKED pin as a test port. <br> $0=$ the LOCKED pin indicates PLL status (default). <br> $1=$ the LOCKED pin outputs a test signal per Register 0x17[2:1]. |
|  | [2:1] | Test Mux | Test mux select bits. <br> $00=$ crystal oscillator output (XO). <br> 01 = PFD pump up clock divided-by-2 (UP/2). <br> $10=$ PFD reference input clock divided-by-2 (FPFD/2). <br> 11 = PFD feedback clock divided-by-2 (FDBK/2). |
|  | 0 | Unused | Unused. |
| 0x18 | 7 | Unused | When programming this register write a Logic 0 to this bit. |
|  | [6:5] | Po divider | Sets the $\mathrm{P}_{0}$ divider to divide-by-5 or divide-by-6. <br> $00=$ invalid. <br> 01 = divide-by-5. <br> $10=$ divide-by-6. <br> 11 = invalid. <br> The $P_{0}$ divider bits are ineffective unless Register $0 \times 14[2]=1$. |
|  | [4:0] | Unused | Unused. |
| 0x19 | [7:0] | Unused | Unused. |

## Input Receiver and Band Gap Control (Register 0x1A)

Table 32.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x1A | 7 | Receiver reset | Input receiver reset control. This is an autoclearing bit. <br> $0=$ normal operation (default). <br> 1 = resets the reference input hardware (detectors, dividers, switchover control, crystal oscillator and its associated frequency doubler). |
|  | [6:2] | Band gap voltage adjust | Controls the band gap voltage setting from minimum (00000) to maximum (11111). Default is 00000 . <br> The band gap voltage adjust bits are ineffective unless Register $0 \times 1 \mathrm{~A}[0]=1$. |
|  | 1 | Unused | Unused. |
|  | 0 | Enable SPI control of band gap voltage | Enables functionality of Register 0x1A[6:2]. <br> $0=$ the device automatically selects receiver band gap voltage (default). <br> 1 = Register 0x1A[6:2] defines the receiver band gap voltage. |

## XTAL Control (Register 0x1B to Register 0x1E)

Table 33.

| Address | Bit | Bit Name | Description |
| :--- | :--- | :--- | :--- |
| $0 \times 1 \mathrm{~B}$ | 7 | Disable SPI control of XTAL <br> tuning capacitance | Disables functionality of Register 0x1B[5:0]. <br> $0=$ tuning capacitance defined by Register $0 \times 1 \mathrm{~B}[5: 0]$. <br> $1=$ the device automatically selects XTAL tuning capacitance (default). |
|  |  |  | When programming this register write a Logic 0 to this bit. |
|  | 6 | Unused | Capacitance value coded as inverted binary $(0.25 \mathrm{pF}$ per bit); that is, 111111 is 0 pF,$$ <br> 111110 is 0.25 pF, and so on. The default value, 000000, is 15.75 pF. <br> The XTAL tuning capacitor bits are ineffective unless Register $0 \times 1 \mathrm{~B}[7]=0$. |
|  | $[5: 0]$ | XTAL tuning capacitor control |  |
| $0 \times 1 \mathrm{C}$ | $[7: 0]$ | Unused | Unused. |
| $0 \times 1 \mathrm{D}$ | $[7: 0]$ | Unused | Unused. |
| $0 \times 1 \mathrm{E}$ | $[7: 0]$ | Unused | Unused. |

## REFA Frequency Control (Register 0x1F to Register 0x22)

Table 34.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x1F | [7:0] | REFA divider ( $\mathrm{R}_{\mathrm{A}}$ ) | Bits[13:6] of the 14-bit REFA divider. |
| 0x20 | [7:2] | REFA divider ( $\mathrm{R}_{\mathrm{A}}$ ) | Bits[5:0] of the 14-bit REFA divider (default: $R_{A}=2048$ decimal). The REFA divider bits are ineffective unless Register $0 \times 20[1]=1$. |
|  | 1 | Enable SPI control of RA | Enables SPI port control of the REFA divider value ( $\mathrm{R}_{\mathrm{A}}$ ). $0=$ The A[3:0] pins define RA per Table 14 (default). <br> $1=$ The 14-bit value in the REFA divider register defines $R_{A}$. |
|  | 0 | Unused | Unused. |
| 0x21 | 7 | Enable SPI control of x2A | Enables SPI control of the REFA $2 x$ frequency multiplier ( $\times 2_{A}$ ) per $0 \times 21$ [6]. $0=$ the device automatically selects $\times 2_{A}$ per Table 14 (default). <br> $1=$ Register $0 \times 21[6]$ controls the selection of $\times 2$. |
|  | 6 | Select $\times 2 \mathrm{~A}$ | $\begin{aligned} & \text { Selects } \times 2_{A} . \\ & 0=\text { bypass } \times 2_{A} \text { (default). } \\ & 1=\text { select } \times 2_{A} \text {. } \\ & \text { This bit is ineffective unless Register } 0 \times 21[7]=1 . \end{aligned}$ |
|  | 5 | Enable SPI control of /5A | Enables SPI control of the $/ 5_{\mathrm{A}}$ prescaler per 0x21[4]. <br> $0=$ the device automatically selects $/ 5_{\mathrm{A}}$ per Table 14 (default). <br> 1 = Register $0 \times 21$ [4] controls the selection of $/ 5_{\mathrm{A}}$. |
|  | 4 | Select $/ 5_{\text {A }}$ | Selects $/ 5 \mathrm{~A}$. $0=\text { bypass } / 5_{\mathrm{A}} \text { (default). }$ $1=\text { select } / 5_{\mathrm{A}} \text {. }$ <br> This bit is ineffective unless Register $0 \times 21[5]=1$. |
|  | [3:0] | Unused | Unused. |
| 0×22 | [7:0] | Unused | Unused. |

## AD9553

## REFB Frequency Control (Register 0x23 to Register 0x26)

Table 35.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x23 | [7:0] | REFB divider ( $\mathrm{R}_{\mathrm{B}}$ ) | Bits[13:6] of the 14-bit REFB divider. |
| 0x24 | [7:2] | REFB divider ( $\mathrm{R}_{\mathrm{B}}$ ) | Bits[5:0] of the 14-bit REFB divider (default: $R_{B}=4096$ decimal). The REFB divider bits are ineffective unless Register 0x24[1] = 1 . |
|  | 1 | Enable SPI control of $\mathrm{R}_{B}$ | Enables SPI port control of the REFB divider value ( $\mathrm{R}_{\mathrm{B}}$ ). $0=$ The A[3:0] pins define $R_{B}$ per Table 14 (default). <br> 1 = The 14 -bit value in the REFB divider register defines $R_{B}$. |
|  | 0 | Unused | Unused. |
| 0x25 | 7 | Enable SPI control of $\mathrm{x} 2_{\text {B }}$ | Enables SPI control of the REFB 2x frequency multiplier ( $\mathrm{x} 2_{\mathrm{B}}$ ) per Register 0x25[6]. $0=$ the device automatically selects $\times 2_{B}$ per Table 14 (default). <br> $1=$ Register $0 \times 25[6]$ controls the selection of $\times 2_{\text {B }}$. |
|  | 6 | Select x2 ${ }_{\text {B }}$ | ```Selects \(\times 2_{\text {b }}\). \(0=\) bypass \(\times 2_{B}\) (default). \(1=\) select \(\times 2_{\text {B }}\). This bit is ineffective unless Register 0×25[7] \(=1\).``` |
|  | 5 | Enable SPI control of / $5_{\text {B }}$ | Enables SPI control of the $/ 5_{\mathrm{B}}$ prescaler per Register 0x25[4]. $0=$ the device automatically selects $/ 5_{\text {в }}$ per Table 14 (default). $1=$ Register $0 \times 25[4]$ controls the selection of $/ 5_{B}$. |
|  | 4 | Select /5B | ```Selects \(/ 5_{\text {B }}\). \(0=\) bypass \(/ 5_{B}\) (default). \(1=\) select \(/ 5_{B}\). This bit is ineffective unless Register 0×25[5] = 1 .``` |
|  | [3:0] | Unused | Unused. |
| 0x26 | [7:0] | Unused | Unused. |

## DCXO Frequency and Reference Switchover Control (Register 0x27 to Register 0x31)

Table 36.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x27 | [7:0] | XO divider (Rxo) | Bits[13:6] of the 14-bit XO divider. |
| 0×28 | [7:2] | XO divider (Rxo) | Bits[5:0] of the 14-bit XO divider (default: $\mathrm{Rxo}=2048$ decimal). The XO divider bits are ineffective unless Register $0 \times 28[1]=1$. |
|  | 1 | Enable SPI control of Rxo | Enables SPI port control of the XO divider value ( $\mathrm{R}_{\mathrm{xo}}$ ). $0=$ The $A[3: 0]$ pins define Rxo per Table 14 (default). <br> 1 = The 14 -bit value in the XO divider register defines Rxo. |
|  | 0 | Unused | Unused. |
| 0x29 | [7:6] | Switchover mode | Selects the switchover operating mode. $00=$ revertive switchover (default). 01 = nonrevertive switchover. $10=$ selects REFA as the active reference. $11=$ selects REFB as the active reference. |
|  | 5 | REFA diff | Enables the differential input reference function. <br> $0=$ normal single-ended operation of REFA and REFB (default). <br> $1=$ REFA configured as a differential reference in which the REFA pin functions as one differential input and the REFB/REFA pin functions as the other differential input. In this configuration, the REFB channel and switchover functionality are both unavailable. |
|  | [4:0] | Unused | Unused. |
| $\begin{aligned} & \hline 0 \times 2 \mathrm{~A} \text { to } \\ & 0 \times 31 \end{aligned}$ | [7:0] | Unused | Unused. |

## OUT1 Driver Control (Register 0x32)

Table 37.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x32 | 7 | OUT1 drive strength | Controls the output drive capability of the OUT1 driver. $0=$ weak. <br> 1 = strong (default). |
|  | 6 | OUT1 power-down | Controls power-down functionality of the OUT1 driver. $0=$ OUT1 active (default). <br> 1 = OUT1 powered down. |
|  | [5:3] | OUT1 mode control | OUT1 driver mode selection. <br> $000=$ CMOS, both pins active. <br> $001=$ CMOS, positive pin active, negative pin tristate. <br> $010=$ CMOS, positive pin tristate, negative pin active. <br> $011=$ CMOS, both pins tristate. <br> $100=$ LVDS. <br> 101 = LVPECL (default). <br> $110=$ not used. <br> 111 = not used. |
|  | [2:1] | OUT1 CMOS polarity | Selects the polarity of the OUT1 pins in CMOS mode. <br> $00=$ positive pin is normal polarity and negative pin is inverted polarity (default). <br> $01=$ positive pin is normal polarity and negative pin is normal polarity. <br> $10=$ positive pin is inverted polarity and negative pin logic is inverted polarity. <br> 11 = positive pin logic is inverted polarity and negative pin is normal polarity. <br> These bits are ineffective unless Bits[5:3] select CMOS mode. See the Output Driver <br> Polarity (CMOS) section for the definition of normal and inverted polarity. |
|  | 0 | Use Bits[5:3] as source for OUT1 mode control | Controls OUT1 driver functionality. <br> $0=$ OUT1 mode determined by the OM[2:0] pins (default). <br> 1 = OUT1 mode defined by Register 0x32[5:3]. |

## Reserved (Register 0x33)

Table 38.

| Address | Bit | Bit Name | Description |
| :--- | :--- | :--- | :--- |
| $0 \times 33$ | $[7: 0]$ | Unused | Unused. |

## AD9553

## OUT2 Driver Control (Register 0x34)

Table 39.

| Address | Bit | Bit Name | Description |
| :---: | :---: | :---: | :---: |
| 0x34 | 7 | OUT2 drive strength | Controls the output drive capability of the OUT2 driver. $\begin{aligned} & 0=\text { weak. } \\ & 1=\text { strong (default). } \end{aligned}$ |
|  | 6 | OUT2 power-down | Controls power-down functionality of the OUT2 driver. $0=$ OUT2 active (default). <br> 1 = OUT2 powered down. |
|  | [5:3] | OUT2 mode control | OUT2 driver mode selection. <br> $000=$ CMOS, both pins active. <br> $001=$ CMOS, positive pin active, negative pin tristate. <br> $010=$ CMOS, positive pin tristate, negative pin active. <br> 011 = CMOS, both pins tristate. <br> $100=$ LVDS. <br> 101 = LVPECL (default). <br> $110=$ not used. <br> 111 = not used. |
|  | [2:1] | OUT2 CMOS polarity | Selects the polarity of the OUT2 pins in CMOS mode. <br> $00=$ positive pin is normal polarity and negative pin is inverted polarity (default). <br> $01=$ positive pin is normal polarity and negative pin is normal polarity. <br> $10=$ positive pin is inverted polarity and negative pin logic is inverted polarity. <br> 11 = positive pin logic is inverted polarity and negative pin is normal polarity. <br> These bits are ineffective unless Bits[5:3] select CMOS mode. See the Output Driver <br> Polarity (CMOS) section for the definition of normal and inverted polarity. |
|  | 0 | Use Bits[5:3] as source for OUT2 mode control | Controls OUT2 driver functionality. <br> $0=$ OUT2 mode determined by the OM[2:0] pins (default). <br> 1 = OUT2 mode defined by Register $0 \times 34[5: 3]$. |
