## 3W Low EMI Class-D Audio Power Amplifier with Auto-Recovering Short-circuit Protection

### **GENERAL DESCRIPTION**

The HM2010 is a high efficiency, low EMI, filterless Class-D audio amplifier with auto-recovering short-circuit protection. It operates from 2.7V to 5.5V supply. When powered with 5V voltage, the

HM2010 can deliver up to 3W into a 4 $\Omega$  load or 1.8W into an 8 $\Omega$  load at 10% THD+N.

As a Class-D audio amplifier, the HM2010 features 90% high efficiency and 75dB PSRR at 217Hz which make the device ideal for battery-powered high quality audio applications.

One of the key benefits of the HM2010 over traditional Class-D audio amplifiers is it generates much lower EMI emissions, thus greatly simplifying the system design for use in portable applications. Also included is the over-current or short-circuit protection with auto-recovery, which ensures the device be operated safely and reliably without the need for system interruption.

The HM2010 is available in 1.5mmx1.5mm COL-9L, MSOP-8L, and DFN2x2-8L package.

### **APPLICATIONS**

- Mobile Phones
- Portable Digital Assistant (PDA)
- MP3/MP4 Player

### FEATURES

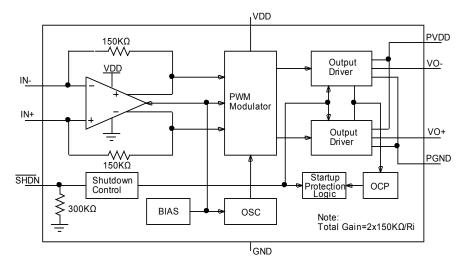

- Filterless Class-D operation
- High efficiency up to 90%
- Output power at 5V supply
  - 3.0W (4Ω load, 10% THD+N)
  - 1.8W (8Ω load, 10% THD+N)
  - 2.4W (4 $\Omega$  load, 1% THD+N)
  - 1.4W (8Ω load, 1% THD+N)
- Low THD+N: 0.05% (typical) @ 1kHz (VDD=3.6V, RL=8Ω, Po=0.5W)
- Low quiescent current: 2mA at 3.6V (8Ω load)
- Extremely low shutdown current: 0.1µA (typical)
- High PSRR: 75dB (typical) at 217Hz
- No bypass capacitor required for the common-mode bias
- Under-voltage lockout
- Auto recovering short-circuit protection
- Over-current & thermal overload protection
- Low EMI design
- Available in 1.5mmx1.5mm COL-9L, MSOP-8L, and DFN2x2-8L packages

### PIN CONFIGURATION AND DESCRIPTION

### **TEST SETUP FOR PERFORMANCE TESTING**

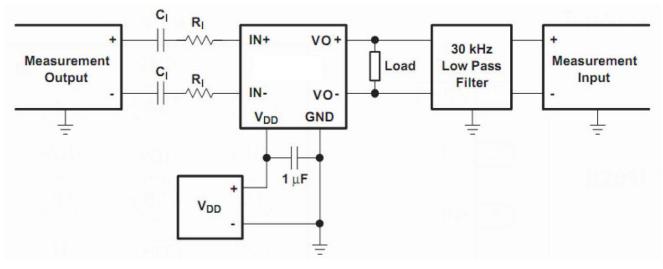

Figure 3: Test Block Diagram

Notes: 1) A 33- $\mu$ H inductor was placed in series with the load resistor to emulate a small speaker for efficiency measurements; 2) The 30-kHz low-pass filter is required even if the analyzer has an internal low-pass filter. An RC low pass filter (100 $\Omega$ , 47nF) issued on each output for the data sheet graphs.

### **APPLICATION INFORMATION**

The HM2010 is a high efficiency, low EMI, filterless Class-D audio power amplifier with auto-recovering short-circuit protection. The HM2010 can operate from 2.7 to 5.5V supply. When powered with 5V voltage, the HM2010 can deliver up to 3W into a  $4\Omega$  load or 1.8W into an  $8\Omega$  load at 10% THD+N.

As a Class-D audio amplifier, the HM2010 features 90% high efficiency and 75dB PSRR at 217Hz which make the device ideal for battery-supplied, high quality audio applications. One of the key benefits of the HM2010 over conventional Class-D audio amplifiers is it generates much lower EMI emissions, thus greatly simplifying the system design for use in portable device applications, thanks to a proprietary output stage. Also included are the short-circuit protection with auto-recovery and the circuitry to minimize turn-on and turn-off transients or "click and pops".

Furthermore, it includes under-voltage lockout to ensure proper operation when the device is first powered up; and over-temperature shutdown to safeguard the die temperature in operation.

#### **Full Differential Amplifier**

The HM2010 is configured in a fully differential topology. The fully differential topology ensures that the amplifier outputs a differential voltage on the output that is equal to the differential input times the gain. The common-mode feedback ensures that the common-mode voltage at the output is biased around VDD/2 regardless of the common-mode voltage at the input. Although the fully differential topology of the HM2010 can still be used with a single-ended input, it is highly recommended that the HM2010 be used with differential inputs in a noisy environment, like a wireless handset, to ensure maximum noise rejection.

#### **Filterless Design**

Traditional Class-D amplifiers require an output filter. The filter adds cost, size, and decreases efficiency and THD+N performance. The HM2010's filterless modulation scheme does not require an output filter. Because the switching frequency of the HM2010 is well beyond the bandwidth of most speakers, voice coil movement due to the switching frequency is very small. Use a speaker with a series inductance larger than  $10\mu$ H. Typical 8 $\Omega$  speakers exhibit series inductances in the 20 $\mu$ H to 100 $\mu$ H range.

However, LC filter is required when the trace between the HM2010 and the speaker exceeds 100mm. Long trace acts like tiny antenna and causes EMI emissions which may result in FCC and CE certification failure.

#### Low EMI Design

Traditional Class-D amplifiers require the use of external LC filters, or shielding, to reduce electromagnetic-interference (EMI). The HM2010 employs a proprietary output stage and frequency jittering technique to minimize EMI emissions while maintaining high efficiency.

#### How to Reduce EMI

Most applications require a ferrite bead filter for EMI elimination. The ferrite filter reduces EMI around 1MHz and higher. When selecting a ferrite bead, choose one with high-impedance at high frequencies, but low impedance at low frequencies.

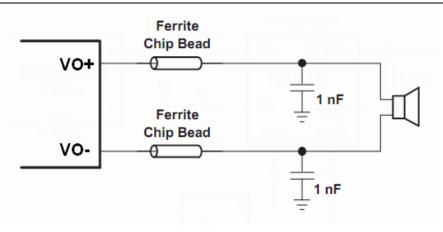

Figure 22: Ferrite Bead Filter to Reduce EMI

#### Shutdown Operation

In order to reduce power consumption while the device is not in use, the HM2010 includes shutdown circuitry to de-bias all the internal circuitry when the  $\overline{SHDN}$  pin is pulled low. During shutdown, the supply current of the HM2010 is reduced less than 0.1µA, typically.

#### Under Voltage Lockout (UVLO)

The HM2010 incorporates circuitry designed to detect a low supply voltage. When the supply voltage drops below 2.0V (typical), the HM2010 goes into shutdown mode. The device will emerge out of the shutdown mode and resume its normal operation only when the supply voltage is restored to above 2.2V (typical) and the SHDN pin pulled high.

#### Short-circuit Auto-Recovery

When an over-current or short-circuit event occurs, the HM2010 goes into shutdown mode. During shutdown, the HM2010 activates auto-recovery process whose aim is to return the device to normal operation once the fault condition is removed. This process repeatedly examines whether the fault condition persists, and returns the device to normal operation immediately after the fault condition is removed. This feature helps protect the device from large currents and maintain long-term reliability while removing the need for external system interaction to resume normal operation.

#### **Over Temperature Protection**

Thermal protection on the HM2010 prevents the device from being damaged when the internal die temperature exceeds 160°C. Once the die temperature exceeds the prescribed value, the device will enter into shutdown state and the outputs are disabled. This is not a latched fault. The thermal fault cleared once the temperature of the die decreased by 30°C. This large hysteresis will prevent it from generating motor boating sound and allow the device resume normal operation without the need for external system interaction.

#### **POP and Click Circuitry**

The HM2010 contains circuitry to minimize turn-on and turn-off transients or "click and pops", where turn-on refers to either power supply turn-on or device recover from shutdown mode. When the device is turned on, the amplifiers are internally muted. An internal current source ramps up the internal reference voltage. The device will remain in mute mode until the reference voltage reach half supply voltage, 1/2 VDD. As soon as the reference voltage is stable, the device will begin full operation. For the best power-off pop performance, the amplifier should be set in shutdown mode prior to removing the power supply voltage.

#### **Components Selection**

#### Input Resistors (RI)

The input resistors (R<sub>I</sub>) set the gain of the amplifier according to equation (1).

$$Gain = \frac{2 \times 150 k\Omega}{R_{I}} (\frac{V}{V})$$
(1)

Resistor matching is very important in full differential amplifiers. The balance of the output on the reference voltage depends on matched ratios of the resistors. CMRR, PSRR, and cancellation of the even-order harmonic distortion diminish if resistor mismatch occurs. Therefore, it is recommended to use 1% tolerance resistors or better to keep the performance optimized. Matching is more important than overall tolerance. Resistor arrays with 1% matching can be used with a tolerance greater than 1%.

Place the input resistors very close to the HM2010 to limit noise injection on the high-impedance nodes. For optimal performance the gain should be set to 2 times of  $R_1$  ( $R_1 = 150k\Omega$ ) or so. Lower gain allows the HM2010 to operate at its best, and keeps a high voltage at the input making the inputs less susceptible to noise. In addition to these features, higher value of  $R_1$  minimizes pop noise.

#### **Decoupling Capacitor (Cs)**

Decoupling capacitor helps to stabilize voltage of power supply and thus reduce the total harmonic distortion (THD). It can also be applied to prevent oscillation over long leads. A Low Equivalent-series-resistance (ESR) capacitor of  $1\mu$ F is required for decoupling and should be placed close to the HM2010 to reduce the resistance and inductance on the trace between the amplifier and the capacitor. For filtering lower-frequency noise signals, a  $10\mu$ F capacitor could be placed near the audio power amplifier.

#### Input Capacitors (C<sub>I</sub>)

The input capacitor and input resistor determine the corner frequency of the high pass filter. The corner frequency (fc) is calculated with the Equation (2) below.

$$f_{c} = \frac{1}{(2\pi R_{I}C_{I})}$$
(2)

The corner frequency directly influences the low frequency signals and consequently determines output bass quality.

#### **PCB Layout**

As output power increases, interconnect resistance (PCB traces and wires) among the audio amplifier, load and power supply create a voltage drop. The voltage loss on the traces between the HM2010 and the load results is lower output power and decreased efficiency. Higher trace resistance between the supply and the HM2010 has the same effect as a poorly regulated supply, increase ripple on the supply line also reducing the peak output power. The effects of residual trace resistance increases as output current increases due to higher output power, decreased load impedance or both. To maintain the highest output voltage swing and corresponding peak output power, the PCB traces that connect the output pins to the load and the supply pins to the power supply should be as wide as possible to minimize trace resistance. The use of power and ground planes will give the best THD+N performance. While reducing trace resistance, the use of power planes also creates parasite capacitors that help to filter the power supply line.

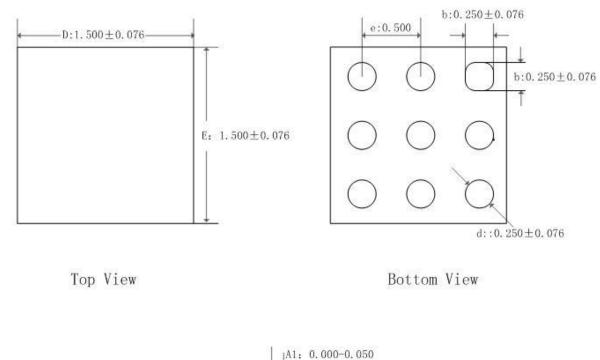

# <A &\$%

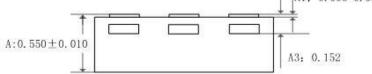

The inductive nature of the transducer load can also result in overshoot on one or both edges, clamped by the parasitic diodes to ground and VDD in each case. From an EMI standpoint, this is an aggressive waveform that can radiate or conduct to other components in the system and cause interference. It is essential to keep the power and output traces short and well shielded if possible. Use of ground planes, beads, and micro-strip layout techniques are all useful in preventing unwanted interference.

As the distance from the HM2010 and the speaker increase, the amount of EMI radiation will increase since the output wires or traces acting as antenna become more efficient with length. What is acceptable EMI is highly application specific. Ferrite chip inductors placed close to the HM2010 may be needed to reduce EMI radiation. The value of the ferrite chip is very application specific.
